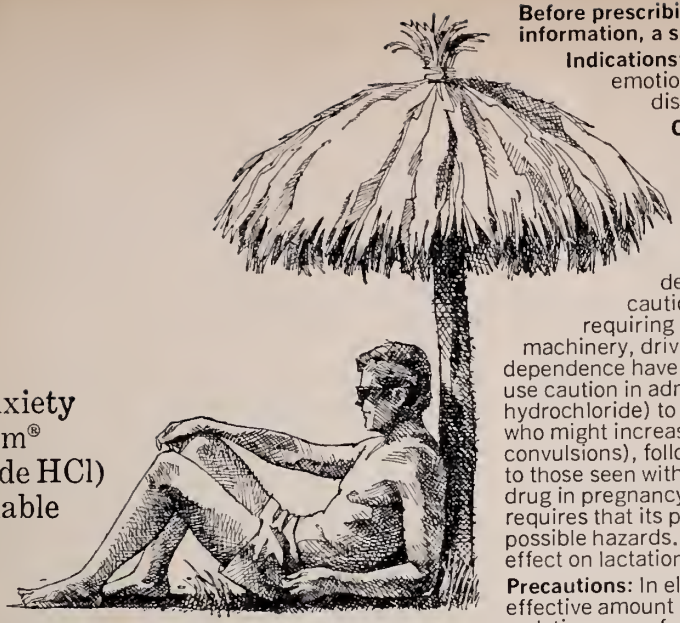
IF MORE MEN CRIED

At least seventy-five out of one hundred adults with duodenal ulcers are men.[1] Why? It may be significant that duodenal ulcer patients tend to crave recognition and are "especially vulnerable to threats to their manly assertive independence."[2]

Hypersecretion—an atavistic response. Stewart Wolf, who, with Harold G. Wolff, studied the personalities of duodenal ulcer patients, wonders if masculine competitiveness is related to "an atavistic urge to devour an adversary." It is striking, he reports, that an accentuation of gastric acid secretion and motility can be "induced in ulcer patients by discussions that arouse feelings of inadequacy, frustration and resentment."[2]

By chance? A lean, hungry lot. Was the link between emotions and gastric hyperacidity acquired through mutation to serve a purpose? During man's jungle period of evolution, the investigator points out, a male dealt with a foe by killing and devouring it. "It may be more than coincidence," he concludes, that peptic ulcer patients appear to be "a lean, hungry, competitive lot."[3]



Big boys don't cry. If more men crie maybe fewer would wind up with duoden ulcers. But men will be men—the sum total their genes and what the are taught. Schottstaed observes that when mother admonishes he son who has hurt himse that big boys don't cry, sh is teaching hi stoicism.[4] Crying is th negation of everythin society thinks of as manly A boy starts defending hi manhood at an early age

Take away stress you can take away symptoms. There is no question that stress plays a role in the etiology of duodenal ulcer. Alvarez[5] observes that many a man with ar ulcer loses his symptoms the day he shuts up the office and starts out on a vacation. The problem is, the type of man likely to have an ulcer is the type least likely to take long vacations or take it easy at work.

The rest cure vs. the two-way action of Librax. For most patients, the rest cure is as unrealistic as it is desirable. Still, the stress factor must be dealt with. And here is where the dual action of adjunctive Librax can help. Librax is the only drug that com-

References: 1. Silen, W.: "Peptic Ulcer," in Wintrobe, M. M., *et al.* (eds.): *Harrison's Principles of Internal Medicine*, ed. 6, New York, McGraw-Hill Book Company, 1970, p. 1444. 2. nes the antianxiety
tion of Librium®
nlordiazepoxide HCl)
th the dependable
tisecretory/
tispasmodic
tion of
iarzan® (clidinium Br).

Protects man from his own hungry personality. The action of Librium reduces xiety—helps protect the vulnerable patient om the psychological overreaction to stress at clutches his stomach. At the same time, e action of Quarzan helps quiet the hyper-tive gut, decreasing hypermotility and persecretion.

An inner healing environment with 1 2 capsules, 3 or 4 times daily. Of course, ere's more to the treatment of duodenal cer than a prescription for Librax. The pa-ent—with your guidance—will have to ad-st to a different pattern of living if treat-ent is to succeed. During this adjustment riod, 1 or 2 capsules of Librax 3 or 4 times ily can help establish a desirable environ-ent for healing.

Librax: It can't change man's nature. ut it can usually make it easier for men to pe with the discomfort of stress—both sychic and gastric—that can precipitate nd exacerbate duodenal ulcer.
ibrax: Rx #60 1 cap. *a.c.* and 2 *h.s.*

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Indicated as adjunctive therapy to control emotional and somatic factors in gastrointestinal disorders.

Contraindications: Patients with glaucoma; prostatic hypertrophy and benign bladder neck obstruction; known hypersensitivity to chlordiazepoxide hydrochloride and/or clidinium bromide.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering Librium (chlordiazepoxide hydrochloride) to known addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards. As with all anticholinergic drugs, an inhibiting effect on lactation may occur.

Precautions: In elderly and debilitated, limit dosage to smallest effective amount to preclude development of ataxia, oversedation or confusion (not more than two capsules per day initially; increase gradually as needed and tolerated). Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (e.g., excitement, stimulation and acute rage) have been reported in psychiatric patients. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: No side effects or manifestations not seen with either compound alone have been reported with Librax. When chlordiazepoxide hydrochloride is used alone, drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally with chlordiazepoxide hydrochloride, making periodic blood counts and liver function tests advisable during protracted therapy. Adverse effects reported with Librax are typical of anticholinergic agents, *i.e.*, dryness of mouth, blurring of vision, urinary hesitancy and constipation. Constipation has occurred most often when Librax therapy is combined with other spasmolytics and/or low residue diets.

in the treatment of duodenal ulcer

• adjunctive

Librax®

Each capsule contains 5 mg chlordiazepoxide HCl and 2.5 mg clidinium Br.

A gratifying announcement about Empirin® Compound with Codeine

You may now specify up to five refills within six months when you prescribe Empirin Compound with Codeine (unless restricted by state law).

It is significant in this era of increased regulation, that Empirin Compound with Codeine has been placed in a less restrictive category. You may now wish to consider Empirin with Codeine even more frequently for its predictable analgesia in acute or protracted pain of moderate to severe intensity.

Empirin Compound with Codeine No. 3 contains codeine phosphate* (32.4 mg.) gr. ½. No. 4 contains codeine phosphate* (64.8 mg.) gr. 1. *(Warning—may be habit-forming.) Each tablet also contains: aspirin gr. 3½, phenacetin gr. 2½, caffeine gr. ½.

Old winner, new bottle.

DBI® phenformin HCl
tablets of 25 mg.
DBI-TD® phenformin HCl
capsules of 50 and 100 mg.

Indications: Stable adult diabetes mellitus; sulfonylurea failures, primary and secondary; adjunct to insulin therapy of unstable diabetes mellitus.
Contraindications: Diabetes mellitus that can be regulated by diet alone; juvenile diabetes mellitus that is uncomplicated and well regulated on insulin; acute complications of diabetes mellitus (metabolic acidosis, coma, infection, gangrene); during or immediately after surgery where insulin is indispensable; severe hepatic disease; renal disease with uremia; cardiovascular collapse (shock); after disease states associated with hypoglycemia.
Warnings: Use during pregnancy is to be avoided.
Precautions: 1. *Starvation Ketosis:* This must be differentiated from "insulin lack" ketosis and is characterized by ketonuria which, in spite of relatively normal blood and urine sugar, may result from excessive phenformin therapy, excessive insulin reduction, or insufficient carbohydrate intake. Adjust insulin dosage, lower phenformin dosage, or supply carbohydrates to alleviate this state. **Do not give insulin without first checking blood and urine sugar.**
2. *Lactic Acidosis:* This drug is not recommended in the presence of azotemia or in any clinical situation that predisposes to sustained hypotension that could lead to lactic acidosis. To differentiate lactic acidosis from ketoacidosis, periodic determinations of ketones in the blood and urine should be made in diabetics previously stabilized on phenformin, or phenformin and insulin, who have become unstable. If electrolyte imbalance is suspected, periodic determinations should also be made of electrolytes, pH, and the lactate-pyruvate ratio. The drug should be withdrawn and insulin, when required, and other corrective measures instituted immediately upon the appearance of any metabolic acidosis.
3. *Hypoglycemia:* Although hypoglycemic reactions are rare when phenformin is used alone, every precaution should be observed during the dosage adjustment period particularly when insulin or a sulfonylurea has been given in combination with phenformin.
Adverse Reactions: Principally gastrointestinal; unpleasant metallic taste, continuing to anorexia, nausea and, less frequently, vomiting and diarrhea. Reduce dosage at first sign of these symptoms. In case of vomiting, the drug should be immediately withdrawn. Although rare, urticaria has been reported, as have gastrointestinal symptoms such as anorexia, nausea and vomiting following excessive alcohol intake.
(B)98-146-103-C

President's Letter

Minnesota Pathologists

IN THE FACE of growing inefficiencies in all fields of human endeavor, the practices of anatomical and clinical pathology have struggled to become more accurate, efficient and up-to-date.

During the 1960s the pathologists developed quality control in the laboratories. This exercise alone greatly improved the proficiency and accuracy in the fields of clinical chemistry, blood banking, hematology, bacteriology and blood coagulation; and Minnesota pathologists were quick to incorporate these new ideas as well as to develop further methods for laboratory quality control.

During the latter part of the 1960s the large auto-analyzer of multiple chemical procedures became a common sight in Minnesota's larger hospitals, and soon clinicians recognized the value of a routine chemical profile on all hospital admissions. Numerous articles were written showing the discovery of unsuspected cases uncovered by the use of screening chemical procedures.

Soon smaller hospitals were developing their own profiles or sending them to larger laboratories. There was a feeling that one can't afford not to do a chemical profile since it often afforded speed of diagnosis on the first hospital admission. In the past, for instance, numerous hospital admissions were sometimes required in order to diagnose moderate hyperparathyroidism. The costs of these profiles were lowered in the face of climbing costs in the rest of the economy.

During 1970 many laboratories in Minnesota developed still further profiles, such as the anemia profile, lipid profile, kidney and liver profiles, in order to diagnose more rapidly and accurately. Chemical fingerprinting of the patient, or following the patient with an annual chemical profile started to become more popular and acceptable. In this way a change in the patient's BUN, for instance, shows up early. A BUN of 28 mgm% may not appear alarming in a 63-year-old patient. However, if it were 10 mgm% the year before and jumped to 28 mgm% in one year for no apparent reason, then further investigation seems necessary. Thus, 1970 appears to be the beginning of real preventive laboratory medicine.

In 1971 the Minnesota pathologists planned further work in quality control for all laboratories in the state with direction from the State Health Laboratories. Legislation is now in process in Minnesota in order to insure that laboratory quality control remains high in this state. Pathologists are also planning to offer better coverage to the smaller hospitals of the state with visitation from pathologists who will direct their laboratories, do autopsies and carry out frozen sections. We are planning better equipped regional laboratories functioning for the purpose of doing more complicated laboratory tests quickly and accurately for the physicians, smaller hospitals and patients of the state. As always we plan to make every effort to train good laboratory personnel and to keep in touch with the school systems of this state in order to inform the counselors of the different levels of laboratory workers.

It is through these efforts that the pathologists, with the help of their colleagues in this state, are hoping to prevent the weak from making the strong weak.

Valvular Competent Patent Foramen Ovale in Adults

RICHARD F. SCHROECKENSTEIN, B.S.*; GREGORY J. WASENDA† AND JESSE E. EDWARDS, M.D.

IN THE ATRIAL SEPTUM of the fetus, it is normal for a channel to be present through which vena caval blood (principally inferior caval) enters the left atrium.

A flap valve guards the channel called the foramen ovale: the so-called valve of the foramen ovale (Figures 1 and 2). At birth, with the onset

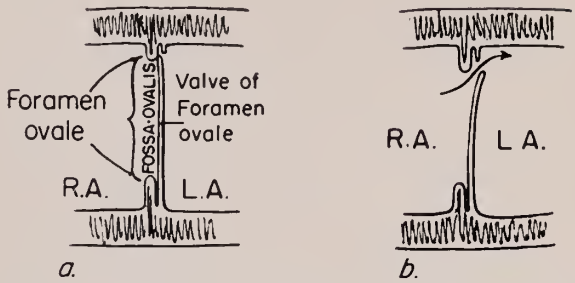

Fig. 1 Diagrammatic portrayal of the atrial septum at the region of the foramen ovale. R.A. = right atrial cavity; L.A. = left atrial cavity. The foramen ovale represents an opening in a component of the septum. On section it appears in two parts. Lying to the left of the foramen is a flap variously called the floor of the fossa ovalis or the valve of the foramen ovale. This flap responds to relative atrial pressures.

From the Departments of Pathology of the Charles T. Miller Hospital, St. Paul, Minnesota and the University of Minnesota, Minneapolis, Minnesota.

This study was supported by Public Health Service Research Grant 5 RO1 HE05694 and Research Training Grant 5 TO1 HE05570 from the National Heart Institute and by the Otto Bremer Foundation.

*Medical Student Research Trainee.
†Research Assistant.

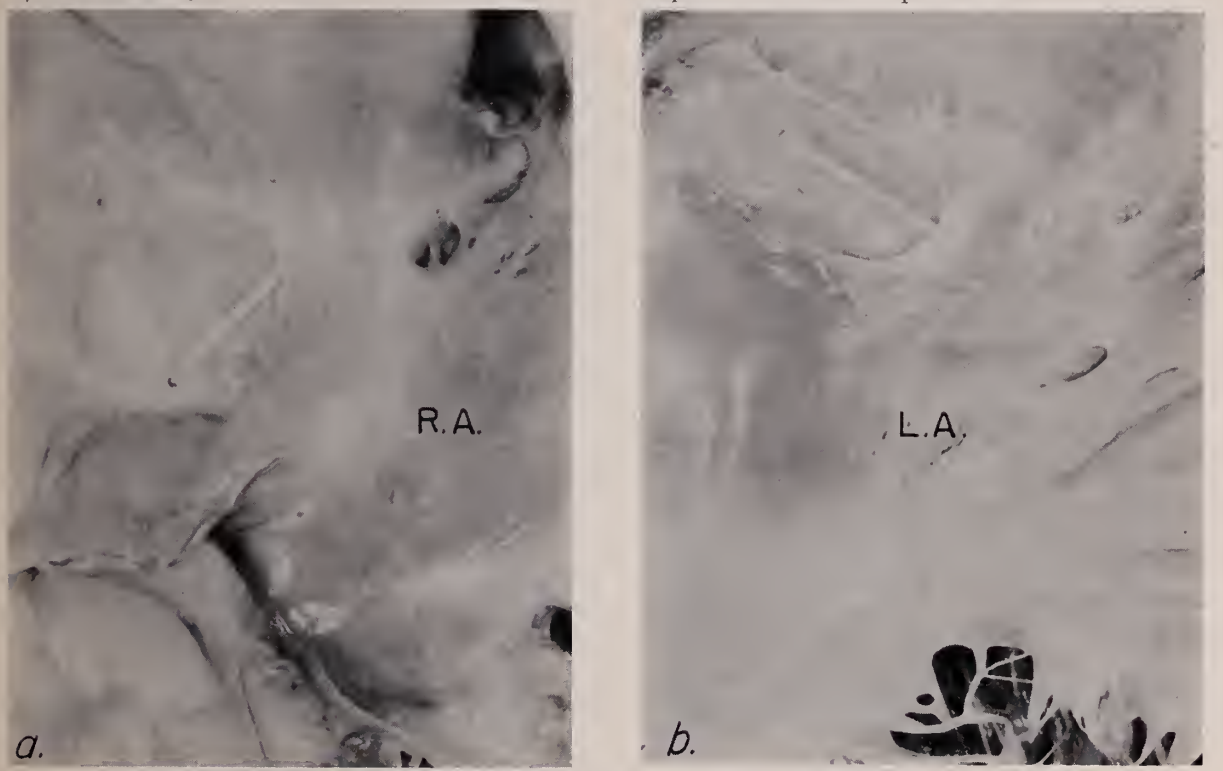

Fig. 2—Valvular competent patent foramen ovale in an adult. *a.* Right atrial (R.A.) aspect. The foramen ovale appears as a circle; the probe placed in the foramen disappears between the edge of the foramen and the floor of the fossa ovalis or valve of foramen. *b.* Left atrial (L.A.) aspect showing the probe placed in the foramen in *a* appearing in the left atrial cavity between the edge of the foramen ovale, on one hand, and the valve of the foramen ovale, on the other. The valve mechanism is such that left atrial pressure in excess of right atrial pressure would tend to close the potential opening.

of respiration, the associated increase in pulmonary blood flow results in a rise in left atrial pressure. This is turn causes the valve flap of the foramen ovale to close the foramen,[1] although episodes of right-to-left, transatrial shunting have been demonstrated in the first week of life.[1,2]

Later, there is a tendency for the valve of the foramen ovale to become adherent to the related structures of the atrial septum so as to cause permanent closure of the foramen ovale (Figure 3). In 1918 Scammon and Norris[3] found the foramen patent in 50 percent of subjects less than five years of age, while in individuals over the age of 20 years, the foramen ovale showed persistent patency in somewhat over 25 percent.

In 1938 Patten[4] reviewed the literature on the incidence of persistent patency of the foramen ovale in adults and found that, in general, this varied from 20 to 25 percent.

Patten named the condition of persistent patency of the foramen ovale, as it occurs in the normal fetus, *probe patent foramen ovale*. Later, one of us (JEE) and co-workers[5] introduced the term *valvular competent foramen ovale* for the same condition.

In view of the variations in incidence of valvular competent foramen ovale reported, we studied hearts obtained at necropsy at the Charles T. Miller Hospital from 144 subjects varying in age from the fourth through the ninth decades (30-89 years; the Table).

The majority of the subjects (112 cases) were in the sixth through the eighth decades, 60 percent of them male. In our material a variety of diseases was represented, including malignant tumors and various forms of cardiac disease principally of coronary and hypertensive types. Cases with congenital heart disease were not included.

There was no significant variation as to the nature of the foramen ovale in males as compared

TABLE

Years in Decades	Number of Cases
30-39	5
40-49	8
50-59	37
60-69	29
70-79	46
80-89	19
Total	144

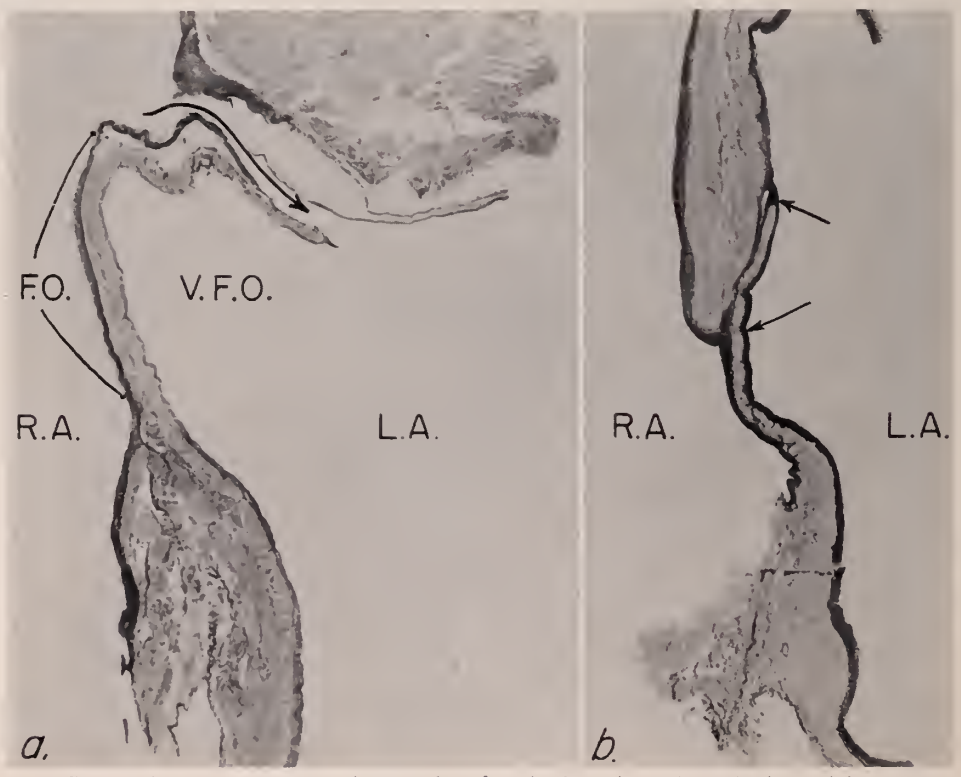

Fig. 3.—Low power photomicrographs of sagittal sections through the atrial septum in two cases. Perspective as in Fig. 1. *a*. The valve of the foramen ovale (V.F.O.) is not sealed to the foramen ovale, allowing a potential opening from right to left (arrow). *b*. The valve of the foramen ovale is sealed (arrows) to the atrial septum so that no potential opening is now present in this case.

with females among the various ages studied.

The average incidence of valvular competent patent foramen ovale in our material was 35.4 percent (Figure 4).

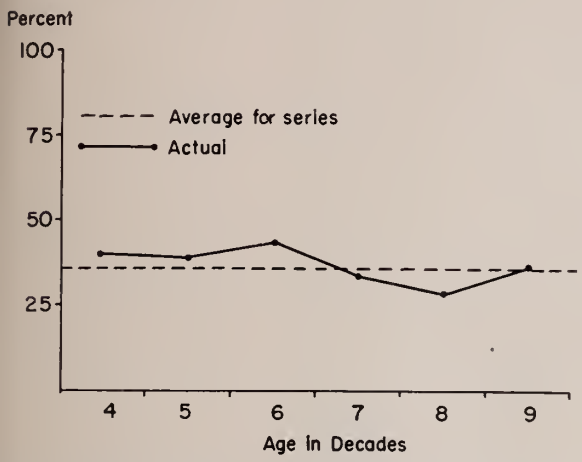

Fig. 4. Graphic portrayal of incidence of valvular competent patent foramen ovale in the various decades studied, the average being 35.4 percent.

Comment

This study on the incidence of valvular competent or so-called probe patent foramen ovale in adults revealed an average of 35.4 percent. This figure is higher than that generally quoted and may reflect the fact that, in this study, particular attention was directed to the foramen ovale. Reports using records of autopsies may yield a lower figure, as there is a tendency for a valvular competent foramen ovale to be overlooked unless a special point is made to determine the state of the foramen ovale.

Our study emphasizes that, in many adult subjects under proper circumstances, blood could potentially flow across the atrial septum.

When a valvular competent foramen ovale is present, its significance depends upon the relative pressures between the two atria. When a normal situation exists and the left atrial pressure is at a level only slightly above that in the right atrium, no flow occurs across the atrial septum. When the left atrial pressure rises to unusually high levels, as in mitral valvular disease, the valve may be pulled backward sufficiently as to create incompetence of the foramen ovale. The resulting left-to-right shunt may cause the right atrium and the foramen ovale to enlarge. The latter situation is a compounding one and may lead to a state in which a true atrial septal defect develops as a secondary condition.

On the contrary, when the pressure in the right atrium rises to a level above that in the left atrium and in the presence of a valvular competent foramen ovale, the valve of the foramen is pushed toward the left as a right-to-left shunt develops. Conditions which favor such an occurrence are right ventricular hypertension, as in pulmonary parenchymal disease, or the rare acquired pulmonary valvular stenosis. A common condition is recurrent pulmonary embolism. In this, once a right-to-left transatrial shunt has developed, further embolism may set the stage for paradoxical embolism.

Summary

Specimens of heart from 144 adult subjects were studied for the incidence of valvular competent foramen ovale ("probe patent foramen ovale"). This was found to average 35.4 percent, a figure higher than generally given in published accounts.

The results of the study emphasize that, in adult patients, a potential for transatrial flow of blood, especially a right-to-left shunt, is common.

Historic Hospitals
The Bimaristan at Jundi Shapur

Anushirwan, Sassanian king and patron of the Bimaristan. Courtesy of the Smithsonian Institution, Freer Gallary of Art, Washington, D. C.

The primitive Christian civilization which followed the fall of the Roman Empire saw the emphasis in care of the sick pass to theological considerations and ideas of individual charity, to the neglect of Greek medical science. Greek medicine in this period was kept alive by a few scholars in the intellectual centers of Syria, but more prominently in the Persian Empire where a renaissance was building under the leadership of its Sassanian dynasty.

Most outstanding of the Sassanian kings was Anushirwan (531-579) who was a generous patron of the university at Jundi Shapur in southwest Persia, and of the hospital built opposite the university. The hospital was known as the Bimaristan, a Persian word meaning "place for the sick." Because of the great influence which this institution exerted over the Arab civilization in the centuries to come, the word "bimaristan" or simply "maristan" came to be the Arabic generic term for hospital.

At the Bimaristan Greek physicians mingled with Persian, Hindu, and Jewish scholars, synthesizing a new medicine, still modeled on Greek methods, but judged superior to all others. There was considerable stress on bedside teaching and on a free exchange of medical ideas. About 550 A.D. Anushirwan convened a symposium on medical subjects presided over by his own personal physician.

In 636 A.D. an Arab army invaded Persia and captured Jundi Shapur. The university and hospital were left undisturbed by the Arabs, but such was their admiration for these institutions that they gradually drained them of their leaders and trained staff to supply the similar hospitals which they built in their own cities.

There was a great interest in the therapeutic action of drugs at Jundi Shapur, and at the Bimaristan was published the first hospital pharmacopeia in history, a work of twenty-two volumes. The greatest Persian medical contribution of all, however, was the very concept of the medical hospital.

Recurrent Pulmonary Embolism

From Upper Extremity Thrombophlebitis

H. BRYAN NEEL, M.D.;* WILLIAM G. HAMMOND, M.D. AND
WILLIAM JOSEPH, M.D.

THROMBOPHLEBITIS of the upper extremity is usually considered a mild disorder, although associated pulmonary embolism has been reported.[1-3] The combination of *septic* thrombophlebitis of the upper extremity and pulmonary embolism is even more unusual and has been reported in severely debilitated patients with signs of lower extremity phlebitis as well.[1,4,5]

Like its counterpart in the legs, septic thrombophlebitis involving the arms is potentially hazardous. The present report illustrates the serious complication of septic pulmonary embolism and infarction following the development of septic thrombophlebitis from an indwelling polyethylene central venous pressure catheter in the arm. Absence of lower extremity thromboembolic disease was suggested on clinical grounds and confirmed by venography. Innominate vein ligation accomplished control of the disease.

Case Report

An otherwise healthy 46-year-old Caucasian male underwent uneventful right hemiglossectomy, hemimandibulectomy, and radical neck dissection with tracheostomy and tube esophagostomy for epidermoid carcinoma† of the tongue. Just prior to operation a polyethylene catheter was inserted percutaneously into the left median cubital vein and advanced into the right artium for central venous pressure measurement and fluid administration. The catheter was removed on the fourth postoperative day. There was no evidence of local infection or superficial phlebitis.

Infection

Eight hours later the patient's temperature rapidly rose to 39° C. even though administration of sodium cephalothin had been continued since the day of surgery. No source of infection was found. Treatment with chloramphenicol was begun empirically and the fever subsided.

The next day he again became febrile. Marked swelling, erythema, superficial venous distension, and tenderness extended from the medial aspect of the left arm into the axilla and over the upper anterior hemithorax. A firm, tender axillary cord was palpable. Continuous warm, moist soaks and a 10-day course of intravenous heparin were begun. In spite of repeated sterile blood cultures, chloramphenicol was continued, sodium cloxacillan was added and sodium cephalothin discontinued. The cellulitis had resolved by the tenth postoperative day.

He remained asymptomatic until the sixteenth postoperative day when fever and leucocytosis recurred. (These persisted during the next six weeks, the temperature ranging between 38-40° C and the white blood count between 15-20,000). No new source of infection was detected clinically. Although the chest x ray was clear, a heavy growth of *Pseudomonas aeruginosa* was cultured from tracheostomy aspirations. Since the initial febrile episode, cultures of tracheostomy aspirate for

†Stage $T_3N_1M_0$.

Mycobacteria and fungi had been repeatedly negative.

Pulmonary Findings

On the nineteenth postoperative day, several small infiltrates appeared in the right upper and left lower lobes on chest xrays. Using ^{131}I-MAA (iodinated macroaggregated serum albumin), a lung scan showed areas of reduced perfusion at the right base. Intravenous heparin was reinstituted, and a five-day course of sodium colistimethate was started. Chloramphenicol and sodium cloxacillin were discontinued.

On the twenty-second postoperative day the patient noted hemoptysis and complained of left-sided pleuritic pain and dyspnea There was no clinical evidence of lower extremity thrombosis. Chest xrays showed a wedge-shaped density in the left lower lobe and a left pleural effusion (Figure 1). An electrocardiogram was normal. A left upper extremity venogram showed complete axillary and subclavian thrombosis with collateralization (Figure 2), while bilateral lower extremity venograms were normal. Subsequent serum lactic dehydrogenase and bilirubin values were compatible with a diagnosis of pulmonary embolism. Thoracentesis produced 200 ml. of bloody sterile fluid.

Additional infiltrates appeared serially, first in the right upper and then in the right-middle lobes, the latter containing an area of central rarefaction suggesting an abscess. The lung scan was repeated and was consistent with reduced perfusion of the entire right lung. Pulmonary angiograms showed multiple emboli in the middle and upper lobe branches of the right pulmonary artery. Repeated blood cultures remained sterile until the thirty-fifth postoperative day when *Staphylococcus epidermidis* was isolated.

Ligation of Vein

During the persistently febrile course, additional transient bilateral small pulmonary infiltrates appeared despite almost 50 days of heparinization, varied antibiotic therapy, and vigorous tracheal toilet. Accordingly, on the sixtieth postoperaitve day the left innominate vein was ligated through an upper median sternotomy. Bronchoscopic examination at operation was unremarkable. The patient's temperature promptly fell with concurrent clearing of the chest xray (Figure 3). Because of persistent copious tracheal secretions, his tracheostomy was reinserted two days later. All antibiotic therapy was discontinued 10 days following vein ligation. No new foci of pulmonary infection appeared. Although minimal edema of the arm occurred shortly after operation, there was no persistent edema, cyanosis or loss of function of the involved arm.

Comment

Septic pulmonary infarction is most often con-

Fig. 2—Venogram demonstrating occlusion of the axillary (arrows) and subclavian veins with extensive collateralization.

Fig. 3—(Left) Chest film before vein interruption showing right upper and lower lobe infiltrates and a left-sided pleural effusion secondary to multiple septic emboli. (Right) Film 10 days after vein interruption showing almost complete clearing.

fused with pneumonia or postoperative atelectasis. Chills, fever, pleuritic pain, hemoptysis and leukocytosis in various combinations are seen in all three conditions and are therefore not useful in the differential diagnosis. When adequate appropriate treatment for pneumonia or postoperative atelectasis is ineffective, the alternative diagnosis of septic pulmonary infarction should be strongly considered. As in our case, review of serial chest xrays will often reveal multiple patchy infiltrates which occasionally show areas of central rarefaction compatible with abscess formation.[8]

Venography is the best available method for confirming the diagnosis of thromboembolic disease and should be done promptly if the clinical impression is at all uncertain. After embolism had recurred in this patient, venograms of the left arm showed axillary and subclavian vein thrombosis. Although there was no clinical evidence of leg thrombosis, because of the rarity of embolism from the arm, venograms of the legs were performed. These were normal, substantiating the clinical impression that the septic emboli originated in the upper extremity. Indar[5] noted one instance of septic pulmonary infarction, presumably from the axillary vein, among the complications of indwelling polyethylene cannulae in the deep veins of 15 severely-burned patients. Crane[4] reported an instance of upper extremity septic phlebitis requiring venous interruption, and, although the patient had repeated pulmonary emboli, there was also associated saphenous phlebitis following bilateral lower extremity indwelling catheters. However, unless lower extremity throboembolic disease is excluded, the diagnosis of upper extremity thromboembolism remains highly suspect.[1] In our case the thromboembolic disease was clearly localized to the upper extremity.

The diagnosis of septic thrombophlebitis is often made on indirect evidence. In 93 cases, Neuhof[6] noted an inflammatory focus in 88%, chills in 66% and positive blood cultures in only 63%. Blood cultures were positive on only one occasion in this case. The growth of *Staphylococcus epidermidis* (albus), often regarded as a "skin contaminent," is seen frequently with intravenous catheter sepsis.[7] Unless treatment is adequate, one may anticipate extension of the process with development of acute bacterial endocarditis, septic pulmonary embolism and infarction, empyema, or metastatic abscess formation elsewhere.[5,8]

Initial management of septic thrombophlebitis includes an intensive course of intravenous heparin and antibiotics, extremity elevation, and local heat. Evidence of continucd sepsis, pulmonary consolidation or infarction are indications for *immediate* vein ligation proximal to the thrombus.[4,8] Although Neuhof in 1947 advocated excision of the infected vein,[6] more recent data[4] supports the conclusion that simple proximal vein ligation is sufficient when combined with intensive antibiotic therapy. Pyogenic foci elsewhere should be drained when present. Ligation and division of major upper exremity veins following thrombosis has not resulted in further edema or dysfunction of the extremity.[4,6]

Recent packaging of sterile catheters with large-bore needles for percutaneous insertion has made venous cannulation quite convenient and, by largely eliminating the surgical cutdown, has encouraged their use for *routine* administration of fluids. The most effective means of reducing venous thrombosis and sepsis from indwelling intravenous polyethylene catheters is to *restrict* their use to specific clinical situations—where a metal needle would be inadequate. The catheter should be removed as early as possible because: (1) a striking increase in positive catheter cultures and bacteremia occurs after 48 hours,[7,9] and (2) as in this instance, the absence of clinically apparent phlebitis may not reliably exclude deep venous disease and its hazardous potential.

Summary

A case of upper extremity septic thrombophlebitis giving rise to repeated septic pulmonary emboli was treated by proximal vein interruption. The disease followed the use of an indwelling venous catheter. Venography was valuable in the early diagnosis and specific localization of thromboembolic disease.

Do Not Die

A "singing commercial" of penny-newspaper days tripped along like this:

Where'er Consumption's victims are,
In palaces or halls,
Or in the rural cottages,
With neatly white-washed walls,
Sink not into despondency,
There's naught for you to fear,
By the pale and flickering taper,
Or the brilliant chandelier;
But drink the draught, 'twil save you,
That bids Consumption fly,
Take DR. SWAYNE'S WILD CHERRY,
And do not, do not die!

Cherry pectorals were a flourishing item. They employed oil of almonds for the cherry flavor and a drug like morphine for the medical principle. Not all the blame falls on the package-medicine industry, however. Peddlers brought raw drugs to the back door. And many a regularly licensed doctor solved his diagnostic riddles with a dose of laudanum or paregoric.*

IT *LOOKS* LIKE WHISKY . . .
IT *TASTES* LIKE WHISKY . . .
IT *FEELS* LIKE WHISKY . . .
BECAUSE IT *IS* WHISKY!

Josh Billings, the popular cracker-box philosopher who panicked them in the 1870s and 1890s, said that if it was necessary to cheat in the "bitters" business, he hoped they'd cut down on the roots but not lower the base. Plantation Bitters, whose base was St. Croix rum, came in a brownish-amber bottle shaped like a log cabin, with a sloping roof. The nostrum first appeared during the Civil War when there was a heavy excise tax on whisky. The patents, being medicine, were exempt. The man behind the product was Colonel P. H. Drake, whose medication was promoted by means of a mysterious combination of letters and figures: "S. T. 1860 X." This bit of occult jargon appeared on fences, barns, billboards and rocks, on mountainsides and at Niagara Falls. It is said that Drake tried to paint his ad on Mount Ararat, the supposed landing place of Noah's Ark—see Genesis 8:4.

The explanation of "S. T. 1860 X" most commonly given was that the cryptogram meant: "Started trade in 1860 with ten dollars capital." But Drake insisted it didn't mean anything.

All the bitters boys put a generous amount of C2H50H into their formulas, "to preserve the medicine." To demonstrate how much, one enterprising doctor at the Battle Creek Sanitarium hooked up a can containing a tablespoon of Hostetter's Bitters to a gas burner and mantel. It had a "breath" that burned brightly for four full minutes. No wonder the medicine was often sold "on premises" by the drink rather than by the bottle, and that Colonel Hostetter made $18,000,000 out of his celebrated comforter.*

Polymyalgia Rheumatica with Temporal and Coronary Arteritis

A Case Report

NATHAN D. MOLLDREM, M.D.* and RONALD OLIN, M.D.†

PATIENTS WITH TEMPORAL (giant-cell) arteritis are known to have involvement of other medium and large-sized arteries. Polymyalgia rheumatica‡ is recognized as being related to giant-cell arteritis and may precede, accompany, or follow it.

The present report describes a woman with polymyalgia rheumatica who developed temporal arteritis followed one year later by probable coronary arteritis.

Case Report

A 65-year-old white housewife of Norwegian extraction was first seen at the Fargo Clinic on January 3, 1967, for evaluation of headaches of six weeks' duration. These were throbbing, generalized, and worse in both temples. Aspirin gave only partial relief. She also had pain in the jaw muscles with chewing and in the muscles of the gluteal areas and anterior thighs. The muscles of the shoulder girdle were not symptomatic. She denied any visual disturbance, fever, anorexia, or weight loss.

Past History

Over the preceding 15 years she had been treated elsewhere by several physicians for recurring myalgias and arthralgias. When 50 years old, she recalled pain in the low back and thighs associated with difficulty in walking. This was treated by weekly injections over a two-month period with some relief. When she was 52 years old, a tonsillectomy was performed because of these myalgias, and this helped for four to five years. When aged 62, she recalled difficulty with pain and stiffness of the neck and left shoulder muscles, and she again received a series of weekly injections with relief. Raynaud's phenomenon from exposure to cold and involving the index and middle fingers of both hands had been present for at least ten years.

Physical Findings

Physical examination revealed a thin, normally developed woman. She was 65 ¾ inches tall and weighed 128 pounds. Blood pressure was 152 systolic and 80 diastolic; pulse, 90 per minute, temperature, 99° F.; and respirations, 20 per minute. Funduscopic examination was normal. The temporal arteries were thickened and tender bilaterally (Figure 1). There was moderate tenderness to pressure of the gluteal and anterior thigh muscles. The arterial pulses were normal. The remainder of the physical examination was unremarkable.

Laboratory

Laboratory studies revealed a hemoglobin of 11.3 gm percent; hematocrit, 35%; and leukocyte count 7,350 per cmm with a differential of 30% lymphocytes, 1% monocytes, 59% segmented neutrophils, 9% band neutrophils, and 1% eosinophils. The erythrocyte sedimentation rate was 105 mm per hour (Westergren). The following labora-

Fig. 1—Shows thickened right temporal artery.

‡See editorial page 47.

tory tests were normal or negative: routine urinalysis, VDRL flocculation test, latex fixation for rheumatoid factor, LE clot test, and serum transaminases. The serum cholesterol was slightly elevated at 291 mg percent. Chest x-ray was normal; x-ray of the cervical spine revealed minimal narrowing of the C-4 and 5 interspace and moderate narrowing of the C-5 and 6 interspace with surrounding lipping and spur formation; x-ray of the dorsal and lumbar spines revealed a minimal thoracic scoliosis and mild hypertrophic changes.

Biopsy of Artery

A biopsy specimen from the right temporal artery at the hairline revealed degenerative changes throughout all layers of the arterial wall with diffuse infiltration by chronic inflammatory cells, particularly in the outer layers of the media. There was marked subintimal fibrous proliferation and fragmentation of the internal elastic membrane. Giant cells were not numerous but were, nevertheless, present in the region of the elastic lamina and also throughout the media. The lumen was stellate and considerably reduced in diameter (Figure 2).

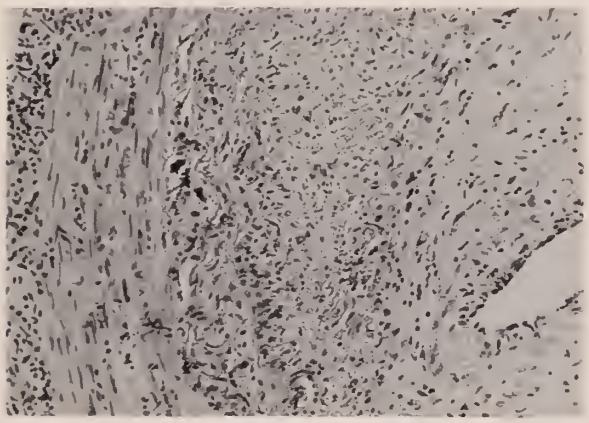

Fig. 2—Photomicrograph of right temporal artery showing diffuse infiltration by chronic inflammatory cells, particularly in the outer layers of the media, marked subintimal fibrous proliferation, fragmentation of internal elastic membrane, and giant cells in the region of the elastic lamina. Hematoxylin and eosin, X100.

Treatment and Progress

Following the biopsy she was started on prednisone, 60 mg daily. After one week the dosage was decreased by 5 mg. decrements at approximately 10- to -..-day intervals. When the daily dosage reached 30 mg, the decrements were changed to 2.5 mg at 10- to 14-day intervals.

The patient was reexamined on February 2, 1967, at which time she was taking 30 mg of prednisone daily. The headaches and pelvic girdle discomfort were no longer present and she felt well. The temporal arteries were no longer thickened or tender. The erythrocyte sedimentation rate was 16 mm per hour (Westergren). An incidental 12-lead electrocardiogram was normal. The prednisone dosage was then gradually decreased and discontinued on July 24, 1967.

In December 1967 the patient noted the gradual onset and worsening of pain and stiffness in the muscles of the neck, shoulders, upper arms, gluteal areas, and thighs, and for the first time a substernal "burning" pain radiating to the neck and coming on with moderate exertion. A 12-lead electrocardiogram now showed low T-waves in the standard leads and deep T-wave inversion in leads V-2 to V-6 (Figure 3). The sedimentation rate was 100 mm. per hour.

With the presumptive diagnosis of polymyalgia rheumatica and probable coronary arteritis, treatment was started with 60 mg of prednisone daily. She was also given nitroglycerin, 0.4 mg sublingually as necessary. When next seen on January 9, 1968, the shoulder and pelvic girdle pains were completely relieved and the effort angina was less frequent. A 12-lead electrocardiogram now showed higher T-waves in the standard leads and upright T-waves in the precordial leads (Figure 3). Prednisone was continued and slowly reduced at the rate of 2.5 mg every two to three weeks.

Comments

Hutchinson (1890) first described temporal arteritis in a man over 80 years of age who had "red streaks on his head," presumably the temporal arteries which later occluded, resulting in scalp necrosis. Horten et al. (1934) described two cases of temporal arteritis which they considered a focal localization of some unknown systemic disease resembling periateritis nodosa. Gilmour (1941) first used the term giant-cell arteritis. and Kilbourne and Wolff (1946) coined the term

TABLE I
Classic Temporal (Cranial) Arteritis

Incidence:	Over age 55 (46-88 years). Slightly commoner in women
Prodromata:	Malaise, weight loss, anorexia, slight fever, sweats, depression, myalgias
Clinic features:	Symptoms—Unilateral or bilateral headaches with pain and tenderness over the temporal artery; jaw pain on chewing; neck, occipital, and facial pain; diplopia and episodic amourosis fugax Signs—Reddened, thickened, nonpulsating temporal artery. Funduscopic examination showing retinal pallor, disk edema, and occasional hemorrhages
Laboratory findings:	Mild normochromic, normocytic anemia; normal or slightly elevated leukocyte count; erythrocyte sedimentation rate between 50 and 100 mm per hour; serum protein electrophoresis showing "stress pattern" of decreased albumin and elevated alpha-2 globulin
Biopsy:	Temporal artery showing a granulomatous infiltration primarily of the media and intima mith mononuclear and giant-cell infiltrations and lumen obliteration
Treatment:	Dramatic response to steroids which should be continued for six months; supplemental anticoagulants if blindness is imminant
Course:	Relapses common in usually less than two and a half years
Complications:	Irreversible blindness 5 to 25% of cases; scalp necrosis

cranial arteritis because of involvement of multiple branches of the common carotid artery. The classic picture of temporal (cranial) arteritis is outlined in Table 1.

Polymyalgia rheumatica was first described in detail by Swedish and European workers in the early 1950's. It received little attention in this country until Polanky et al. (1965) reported the first American case. The syndrome is briefly summarized in Table 2 and is considered one manifestation of a systemic giant-cell arteritis (Table 3). Neulengrecht and Schwartz (1952) described 78 patients with periarthrosis humeroscapularis with weight loss, fever and an elevated sedimentation rate. Barber (1957) first suggested the term polymalgia rheumatica in a report of 12 cases. Paulley (1956) was the first to suggest that the clinical picture of polymyalgia rheumatica was identical with the prodromic manifestations of temporal arteritis. This was confirmed by Alestig and Barr (1963) who demonstrated the characteristic giant-cell arteritis on biopsy of seven of 10 patients with polymyalgia rheumatica and asymptomatic, nontender temporal arteries. Hamrin, Jonson and Landberg (1964) verified this finding in 23 patients with polymyalgia rheumatica of

TABLE 2
Polymyalgia Rheumatica

Synonyms:	Senile arthritis. Arthritic rheumatoid arthritis. Pseudopolyarthrite rhizomelique. Periarthrosis humeroscapularis. Periextra-articular rheumatism. Myalgic syndrome of the aged with systemic reaction. Giant-cell arteritis of the aged
Incidence:	Estimated by Dixon (1966) to be similar to gout in the general population and half as common as rheumatoid arthritis at age 70. Age and sex the same as temporal arteritis
Prodromata:	Same as temporal arteritis
Clinical features:	Usually an insidious onset with prodromata and slow progression; occasionally an abrupt onset without prodromata; moderately severe shoulder and pelvic girdle pain and tenderness without weakness
Laboratory findings:	Same as temporal arteritis; blood studies of muscle enzymes and electromyography normal
Biopsy:	Muscles microscopically normal; temporal arteries showing giant-cell arteritis in over 50% of cases despite no headache or tenderness
Treatment:	Same as temporal arteritis
Course:	Usually benign and self-limited (six to eighteen months); occasionally protacted with relapses (two to five years)
Complications:	See Table 3

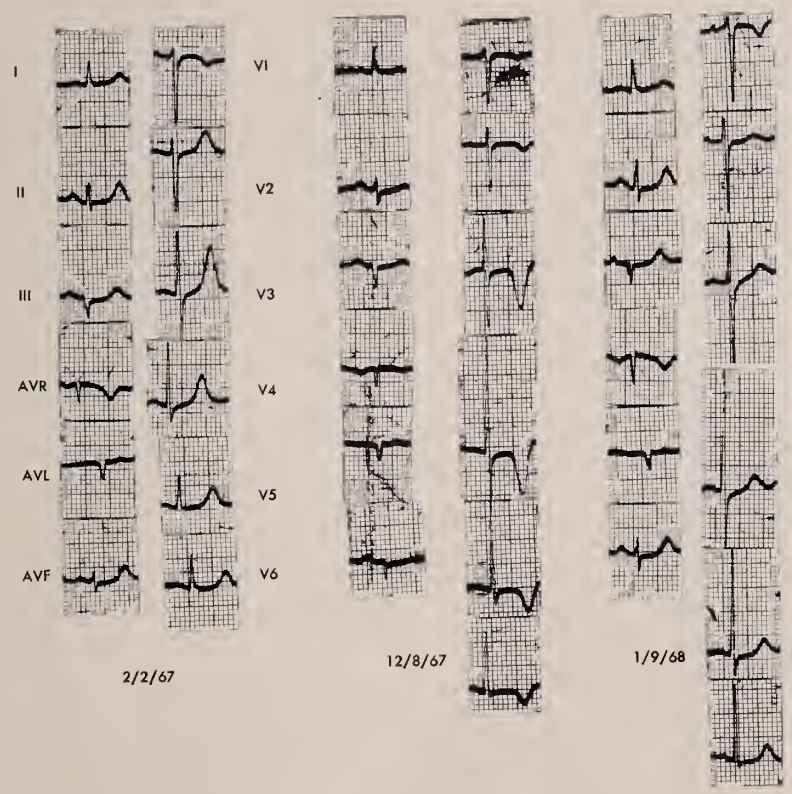

Fig. 3—Electrocardiogram tracings from three examinations.

which 21 had a biopsy of an asymptomatic temporal artery and 12 showed giant-cell arteritis and four nonspecific inflammation. This same group reported in 1965 that four of their patients demonstrated arterial stenosis on aortography of which four subsequently developed an aortic-arch syndrome. One patient came to autopsy which showed giant-cell arteritis of the involved vessels.

Paulley and Hughes (1960) in a classic study of 76 patients with giant-cell arteritis reviewed 15 case histories in detail and noted that 42 percent of patients presented with polymyalgia rheumatica and 39 percent with ocular manifestations. They outlined the protean manifestations of the condition and showed how these cut across all fields of medicine (Table 3).

TABLE 3
The Protean Manifestations of Giant-Cell Arteritis

Arteries	Clinical features	Selected references
Internal and external carotids and vertebrol-basilar and branches	Depression Psychosis Confusion Vertigo Deafness Blindness Cranial nerve palsies Hemiparesis Hemiplegia	Cordell and Hanley (1951) Crompton (1959) Fisher (1959) Paulley and Hughes (1960)
Aortic arch and branches (subclavian, innominate, axillary, and brachial)	Pulseless disease; variable combinations of occlusive or aneurysmal disease or both	Hunder and associates (1967)
Coronary	Insufficiency and infarction	Paulley and Hughes (1960) Morrison and Abitbol (1955)
Mesenteric, renal iliac, and uterine	Insufficiency and infarction syndromes	Russell (1959) Balmforth (1964) Cooke (1946)

Mortality

Mortality figures on giant-cell arteritis tend to vary according to the selection of patients. Schick (1958), in reporting 75 cases of temporal arteritis, noted no mortality. Mosher (1959) reported 11 deaths from vascular complications in 32 patients with giant-cell arteritis. Autopsy studies have shown involvement of the temporal, occipital, ophthalmic, carotid, vertebral, innominate, subclavian, aortic arch, mesenteric, renal, iliac, and uterine arteries. Crompton (1959) did a careful arterial dissection in a patient who died from a myocardial infarction with giant-cell arteritis in the coronary arteries and who presented with temporal arteritis and blindness. He demonstrated that the arterial involvement occurred in a skip rather than in a uniform distribution throughout the vessel. This would explain the tendency to aneurysm formation and the occasional negative biopsy of seemingly involved temporal arteries. This histologic picture was that of a panarteritis of medium and large vessels with giant-cell, granulomatous formation, fragmentation of the elastic fibers of the media, and intimal thickening producing obstruction of the lumen and thrombus formation.

A moot point is what actually produces the girdle-muscle pain in polymyalgia rheumatica. The muscles are normal histologically, by blood enzyme determination, and by electromyography, but the vessels supplying these muscles have never been examined in the acute phase of the disease. It is very likely that these vessels are inflamed, with the resultant ischemia producing the pain.

Differential Diagnosis

The differential diagnosis of giant-cell arteritis with polymyalgia rheumatica involves consideration of an occult malignancy, infection or lymphoma, rheumatoid arthritis, polymyositis, and periarteritis nodosa. Careful laboratory investigation and observation of cases over a prolonged period helps to rule out carcinoma, infection, or lymphoma. Rheumatoid arthritis is also ruled out by the absence of synovitis, joint destruction, and negative tests for rheumatoid factor. Polymyasitis causes girdle weakness with little pain and tenderness; muscle biopsy, blood enzyme studies, and electromyography are diagnostic. Periarteritis nodosa involves smaller arterioles and venules and has a different clinical spectrum and histologic appearance.

Our case presented with temporal arteritis and likely polymyalgia rheumatica involving the pelvic girdle muscles. We would be inclined to dismiss her previous 15-year history of intermittent myalgias and arthralgias as being due to fibrositis or muscular rheumatism rather than remissions and exacerbations of polymyalgia rheumatica. Despite the presence of headaches for six weeks, she did not experience any of the usual prodromata, which is unusual for temporal arteritis. She also had no visual disturbance or funduscopic changes, although intermittent claudication of the jaw muscles on chewing was present. The response to steroids was dramatic, and these were slowly reduced and discontinued in six months which, in

retrospect, was perhaps a little too early.

When seen again approximately one year after the onset of temporal arteritis, she demonstrated the classic clinical picture of polymyalgia rheumatica involving both the shoulder and pelvic girdles and angina with effort. The angina was likely on the basis of coronary arteritis rather than coronary atherosclerosis. Coronary arteritis has been described previously by Morrison and Abitbol (1955), Crompton (1959), and Paulley and Hughes (1960). Equal blood pressures in both arms and normal and equal pulses in the upper extremities seemed to rule out any significant degree of aortic-arch involvement, although minor involvement of the arch affecting the coronary ostia could not be ruled out without coronary angiography. The electrocardiogram had changed and showed ischemic changes. Again, the polymyalgia rheumatica and coronary arteritis responded dramatically to steroids. The electrocardiogram reverted to near normal after one month, which would be unlikely if the angina was caused by coronary atherosclerosis. Follow-ups revealed that she continued to do fairly well and steroids will be maintained for a longer period than for the previous episode.

Raynaud's phenomenon is unusual in giant-cell arteritis with polymyalgia rheumatica. The fact that it did not occur during the winters of 1967 and 1968 while she was taking steroids can probably be explained by the tendency of steroids to have a vasodilating effect.

The disease could continue to smolder for another one to three years before "burning out." It is conceivable, however, that the patient could develop other vascular manifestations of giant-cell arteritis in this interval.

Conclusion

Temporal arteritis and polymyalgia rheumatica should be suspected in any patient over 55 years of age who develops girdle muscle pains with or without involvement of medium and large-sized arteries anywhere in the body. The sedimentation rate may be elevated over 50 mm per hour and the response to steroid therapy can be dramatic.

Laboratory Letter

So You Suspect Cushing's Syndrome

And well you might.

After all, Cushing's syndrome can present as diabetes, hypertension, obesity, osteoporosis, polycythemia, menstural problems, muscle weakness or wasting, hirsutism, mental disorders, purple striae, ecchymoses, or acne.[1] So many symptoms and signs might lead you to suspect Cushing's syndrome. But heretofore you have not had any simple and reliable means of excluding the diagnosis.

Urine tests for 17-ketogenic and 17-hydroxysteroids are reliable, but they are not simple. You have to instruct your patient how to collect a 24-hour urine sample; you may have to hospitalize him for accurate urine collection; and you have to worry about drug interference.[2] Besides, your patient, if he is saddled with the job of bottling his output at home, he has to stay next to a bulky container for hours; then suffer the indignity of carrying it around.

Serum Cortisol

If you wish to rule out Cushing's syndrome simply, you might consider ordering a serum cortisol. This test requires five ml. of serum, and but a few minutes of the patient's time for a venipuncture.

Proponents of the Single Dose Dexamethasone Suppression Test say you can screen for Cushing's with a single venipuncture for a serum cortisol determination.[3,4] You simply tell your patient to swallow a one mg. dexamethasone tablet between 11 P.M. and midnight. Then you instruct him to have his blood drawn for a serum cortisol test at 8 A.M. the next morning.

If the 8 A.M. value falls below 10 mcg./100 ml., you can essentially rule out Cushing's syndrome.[4] If the level exceeds 10 mcg./100 ml., you may have a case of Cushing's syndrome on your hands, and you should go ahead with definitive urine tests.

Clark T. Sawin, of the Boston Veterans' Hospital, believes a single test oversimplifies matters.[5] He suggests three venipunctures for serum cortisol levels—the first two at 8 A.M. and 5 P.M. to establish the patient's normal diurnal variation, and the third at 8 A.M. after one mg. of dexamethasone the previous night. According to Doctor Sawin, the normal range for the first 8 A.M. sample is 8 - 29 mcg./100 ml., for the 5 P.M. value 4 - 20 mcg./100 ml., and for the 8 A.M. value after dexamethasone less than 2.0 to 7.4 mcg./100 ml.

Reasoning

The reasoning behind the single and triple venipuncture methods is the same. Serum cortisol level of the normal person peaks at 8 A.M. (mean 16 mcg/100 ml.) and ebbs to its low point (mean) eight mcg./100 ml.) between 5 P.M. and 9 P.M. Dexamethasone taken between 11 P.M. and midnight suppresses the 8 A.M. value, usually below five mcg./100 ml. (mean four mcg./100 ml.).

Not so with Cushing's syndrome patients. Their plasma cortisols stay at high levels (usually above 20 mcg./100 ml.); don't fluctuate diurnally; and are not significantly suppressed by dexamethasone.

Neurofibromatosis and Hypertension

Due to Pheochromocytoma or Renal-Artery Stenosis

JOSEPH D. LYNCH, M.D.*; SHELDON G. SHEPS, M.D.†; PHILIP E. BERNATZ, M.D.‡
WILLIAM H. ReMINE, M.D.‡ AND EDGAR G. HARRISON, JR., M.D.#

THE OCCURRENCE of hypertension in patients with neurofibromatosis has been of interest over the years, particularly because of the relationship to pheochromocytoma. More recently, association of a number of vascular abnormalities with neurofibromatosis has been noted. Many of these patients are hypertensive, apparently because of neurofibromatous involvement of the renal arteries.

We reviewed the experience of the Mayo Clinic with combined neurofibromatosis and hypertension over a period of 20 years, and report here two of the cases with recent treatment. The hypertension was due to pheochromocytoma in one of these, and to bilateral renovascular stenosis in the other

Incidence

From 1950 through 1969, pheochromocytoma was diagnosed in 132 cases at this institution. The diagnosis was made preoperatively in 113 and confirmed by exploration. In the remaining 19, the discovery of the tumor was incidental to other surgery or autopsy. During the same period, neurofibromatosis was diagnosed clinically in approximately 600 patients, of whom 15 had sustained diastolic hypertension (greater than 90 mm. Hg.). The combination of pheochromocytoma and neurofibromatosis occurred in three cases—which amounted to 2.3% of the 132 with pheochromocytoma and 0.5% of the approximately 600 with neurofibromatosis. We had no cases of pheochromocytoma associated with Sturge-Weber syndrome, tuberous sclerosis, or von Hippel-Lindau syndrome. Excretory urography, carried out in the remaining hypertensive patients with

neurofibromatosis, suggested the possibility of renal-artery disease in one case. Renal angiography was not done.

Case Reports

Case 1

An adopted white boy was first seen in 1952 at two years of age. Physical examination revealed café au lait spots and many neurofibromas. Blood pressure was 105/60.

At age five, the blood pressure was found to be 170/120 and funduscopic examination disclosed arteriolar narrowing, grade 1. Normal results were obtained from excretory urography and a phentolamine (Regitine) test for pheochromocytoma, and the plasma concentrations of catecholamines also were normal. A mass removed from the posterior mediastinum was identified as a plexiform neurofibroma (Figure 1). The patient was dismissed with prescriptions for reserpine (Serpasil) and hydralazine (Apresoline); but administration of them was discontinued by his local physician, apparently because they produced excessive sleepiness.

In 1960, at age 10, the patient had blood pressure of 170/110; and reserpine was prescribed again. In January, 1961, right hemiparesis and right facial weakness suddenly developed; but they gradually improved, though a slight right-sided limp persisted. Urinary and blood catecholamine levels again were normal, as were the results of excretory urography and the phentolamine test. The patient was not seen from 1961 to 1968, during which time he intermittently took antihypertensive drugs under the direction of his local physician.

He returned in September 1968 at the age of 18. He felt well and was taking no medicine, but had many café au lait spots and cutaneous neurofibromas (Figure 2). The blood pressure was 180/125. Funduscopy revealed moderate retinal arteriolar narrowing. A loud systolic bruit heard over the abdominal aorta extended laterally toward both flanks, being louder on the right. Skeletal neurofibromatosis was evident in roentgenograms of the cervical and lumbar vertebrae and left sixth rib. Urinary excretion of aldosterone, catecholamines, metanephrines, and vanilmandelic acid (VMA) was normal. An isotope renogram revealed bilaterally equal function. Inulin clearance was 149 ml./min./1.73 sq. m. and para-aminohippuric acid (PAH) clearance was 900 ml./min./1.73 sq. m. An aorticorenal arteriogram revealed high-grade stenosis at the origin of each renal artery, the superior mesenteric artery, and the celiac axis (Figure 3). Renins were obtained after three days on a regimen of 20 mEq dietary sodium and 1.0 gm. of chlorothiazide (Diuril) daily. The value from the low inferior vena cava was 120 ng./L/min. and that from the left renal vein 130 (the sample from the right was lost in a laboratory accident).

Surgery was carried out in October: for stenosis at the origin of the superior mesenteric artery, endarterectomy and Dacron-patch arterioplasty; for stenosis at the origin of the right renal artery, an aorto-renal artery Dacron bypass; and for stenosis at the origin of the left renal artery, a Dacron-patch arterioplasty. The stenosis was tight and fibrous in each instance. Small neurofibromatous masses were spread over the aorta and particularly around the celiac ganglion and region of the renal vessels, and biopsy proved that they were plexiform neurofibromas (Figure 4). Biopsy of the left kidney (Figure 5) disclosed slight changes of the ischemic type.

Postoperatively the patient continued to be hyper-

Fig. 2—(Case 1). Numerous café au lait spots and large neurofibroma in right popliteal space. Thoractomy scar also is visible.

tensive (170/120), and methyldopa (Aldomet) and guanethidine (Ismelin) were prescribed. A postoperative isotope renogram revealed a delayed peak and slowed excretion on the left.

He returned for re-evaluation in April 1969, having taken no medicine for a month. The blood pressure averaged 135/90. There were no abdominal bruits. An isotope renogram revealed bilaterally equal function, definitely better on the left than indicated by the renogram made just after the operation in the preceding October. The results of excretory urography were normal except for some slight atrophy of the upper pole of the left kidney. Creatinine clearance was 137 ml./min./1.73 sq. m.

In April 1970 the patient's blood pressure was 150/100 without medication. Mild arteriolar narrowing but no sclerosis was seen on funduscopic examination. The inulin clearance was 149 and para-aminohippuric acid clearance 660. The findings from excretory urography and renography were unchanged from 1969. Repeat arteriography revealed moderate focal stenosis just distal to the origin of the left renal artery and a patent graft to the right renal artery (Figure 6). There was minimal focal stenosis just distal to the origin of the superior mesenteric artery. An area of possible infarction in the medial aspect of the upper pole of the left kidney was noted again. Urinary excretion of catecholamines, metanephrines, vanilmandelic acid and homovanillic acid was normal. The patient was dismissed with a regimen that restricted dietary sodium but did not

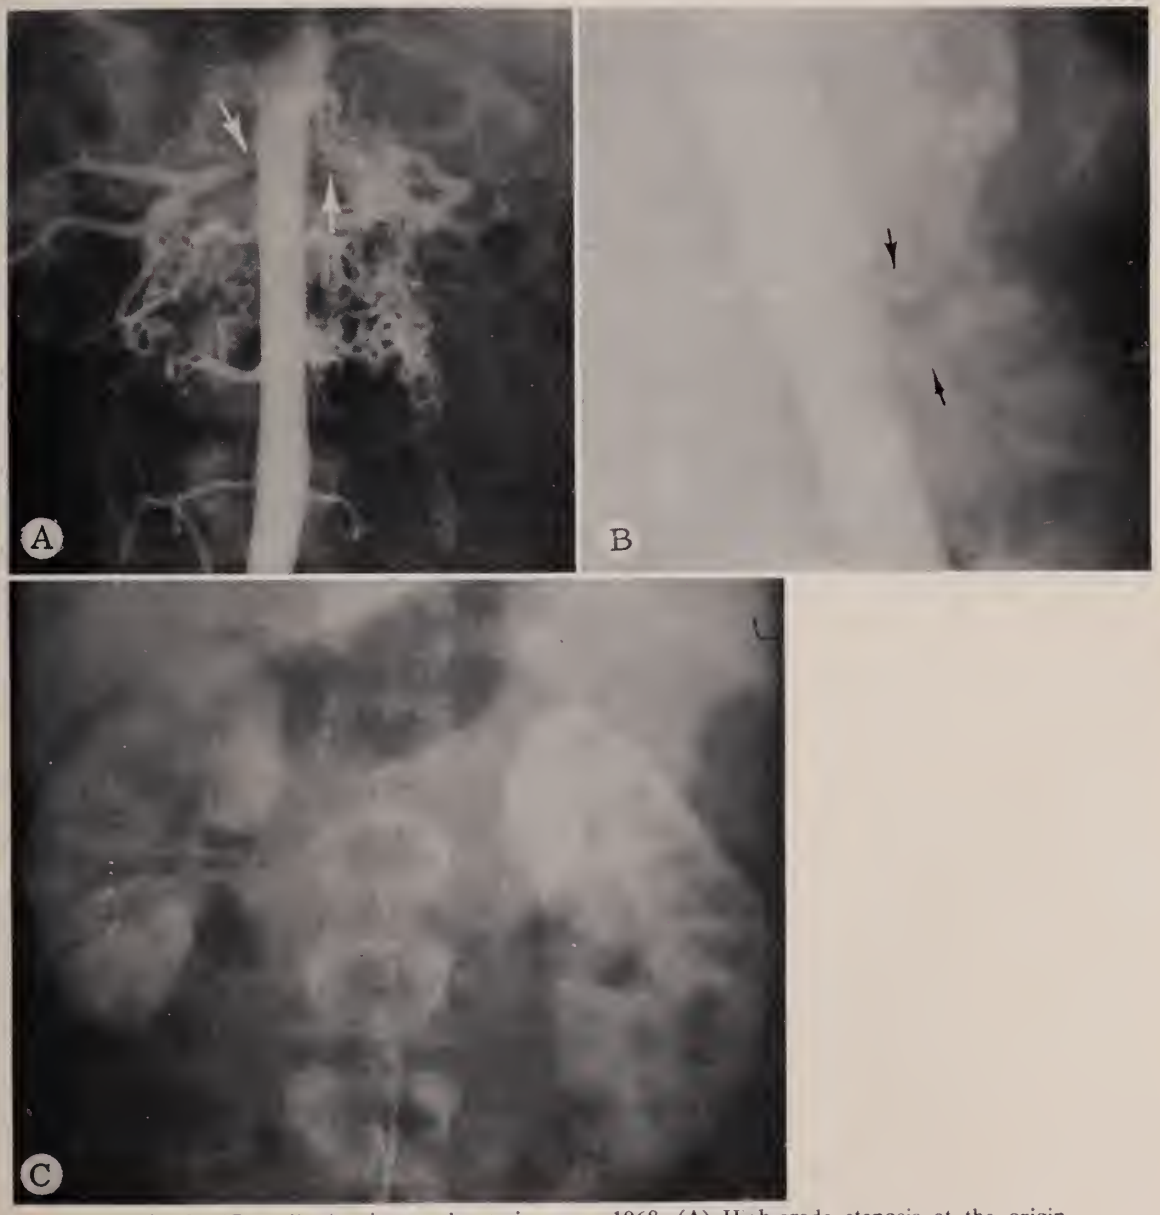

Fig. 3—(Case 1). Aortico-renal arteriograms, 1968. (A) High-grade stenosis at the origin of each renal artery; rich collateral network. (B) Moderate stenosis at origin of celiac axis and superior mesenteric arteries. (C) Nephrographic phase demonstrating both kidneys.

include any drugs. In June 1970 the blood pressure was averaging 125/95 without medication.

Case 2

A 39-year-old white woman was seen in September 1969 because for three years she had been having episodes of occipital headache, diaphoresis, pallor, and palpitations. These began suddenly and usually lasted less than 15 minutes. Transient elevation of blood pressure during the episodes had been recorded. She had had café au lait spots since childhood, and in 1952 a biopsy had confirmed neurofibromatosis. Her mother and one brother were reported to have neurofibromatosis, and three of the patient's children had café au lait spots.

On physical examination the multiple café au lait spots (Figure 7) and neurofibromas were noted. The blood pressure was 129/80. Funduscopy revealed arteriolar sclerosis, grade 1. A systolic ejection murmur, grade 2/6, was heard in the aortic region. During the initial examination two attacks she described as "typical," in which the blood pressure rose to 250/160, were precipitated by palpating the right upper quadrant of the abdomen. A 24-hour urine collection, begun immediately, gave elevated values (numbers in parentheses are upper limits of normal): metanephrines, 34.2 mg. (1.3); vanilmandelic acid, 196 mg. (6.5); homovanillic acid, 19.6 mg. (6.0); and catecholamines, 6,550 μg. (338). A second urine collection confirmed the excess of metanephrines, 22.4; vanilmandelic acid, 44.7; and catecholamines, 2,235. Also the plasma concentration of catecholamines was high, at 21.7 μg./L (5.7 being the upper limit of normal). Creatinine clearance was 105 ml./min./1.73 sq. m. Roentgenographic examination disclosed evidence of neurofibromatosis in the skull and thoracic vertebrae. In the course of nephrotomography, a large mass at the upper pole of the right kidney was demonstrated (Figure 8).

For seven days prior to operation, the patient was given phenoxybenzamine (Dibenzyline), 10 mg. every six hours. Propranolol, 20 mg three times daily, was added four days before surgery; and cortisone acetate, 200 mg., was given for three days and on the morning of the operation.

A well-encapsulated pheochromocytoma, 10.5 by 6 by 3.5 cm., was found in the right adrenal, and the whole gland was removed. The entire specimen weighed 161 gm. Histologic examination revealed typical large polygonal cells (Figure 9). Ganglion-like neural elements, which had been scattered in the pheochromocytomas in several earlier cases where we had noted excessive urinary amounts of homovanillic acid,[1] were not present in the material available for histologic study in this case but may have been contained in the portion used for chemical analysis.

Postoperatively the course was uneventful. The blood pressure was normal and the episodes complained of originally did not recur. In a 24-hour urine collection, the amount of metanephrines was normal (1.2 mg.). In September 1970 she was well and the blood pressure was normal.

Comment

Neurofibromatosis and Pheochromocytoma.

The relationship of pheochromocytoma and neurofibromatosis was first noted by Suzuki[2] in 1910. Mackeith[3], reviewing the literature in 1944, observed that 165 cases of pheochromocytoma had been reported, and that neurofibromatosis had been associated in nine of them. Davis and associates[4] reviewed the literature to 1950 and estimated that the incidence of neurofibromatosis in patients with pheochromocytoma was about 5%, since 10 of 203 patients with pheochromocytoma also had neurofibromatosis.

In 1953 Glushien and co-workers[5] estimated that as many as 10% of patients with pheochromocytoma might have "neurocutaneous syndromes" and suggested that pheochromocytoma, neurofibromatosis, tuberous sclerosis, Sturge-Weber syndrome, and von Hippel-Lindau syndrome were all of common ectodermal origin and

Fig. 8—(Case 2). Nephrographic study: large mass at upper pole of right kidney is outlined.

thus likely to appear in combination wih significant frequency. Glushien and associates presented three cases—one of neurofibromatosis and pheochromocytoma and two of neurofibromatosis and von Hippel-Lindau syndrome. In recent years, the association between pheochromocytoma and "neurocutaneous" or other disorders, including medullary thyroid carcinoma, has been noted and discussed by others.[6-16] Schimke and co-authors[17] suggested that this syndrome may represent a possible heritable regulatory defect in the differentiation of chromaffin tissue or neural-crest derivatives. Hermann and Mornex[18] cited remarkable findings in an autopsy series by Schlegel: Among 25,274 cases in 13 years, there were 15 with neurofibromatosis and 23 with pheochromocytoma; and these abnormalities occurred together twice. That is, of the 23 cases of pheochromocytoma, two (8%) included neurofibromatosis; and of the 15 cases of neurofibromatosis, two (13%) included pheochromocytoma. As mentioned earlier, in our series the incidence of neurofibromatosis among patients with pheochromocytoma has been 2.3% and the incidence of hypertension due to pheochromocytoma among patients with neu-

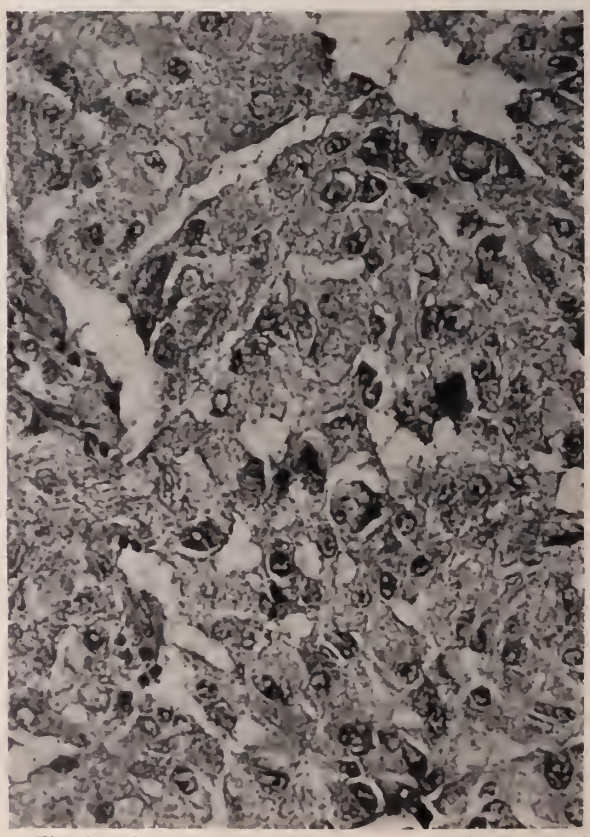

Fig. 9—(Case 2). Pheochromocytoma of right adrenal having typical large polygonal cells with granular cytoplasm. (Hematoxylin and eosin; x350.)

rofibromatosis has been less than 1%.

Neurofibromatosis and Renal-Artery Stenosis

The various renovascular abnormalities reported with neurofibromatosis appear to be a rare cause of hypertension. This relationship has been reviewed fairly recently[19,20]; and two cases since added by Smith and associates[21] and our Case 1 (above) bring the instances of renovascular abnormalities apparently causing hypertension to 15. Of the 15 patients, 14 had neurofibromatosis and one had only café au lait spots. All had renal-artery stenosis or aneurysms, and five had bilateral renal vascular abnormalities. Five had coarctation of the aorta, at least seven had microscopic evidence of neurofibroma or ganglioneuroma in the arterial wall, and three had the pathologic findings of intimal fibrosis, disorganization of the media, and fibrotic changes of the adventitia referred to as "vascular neurofibromatosis."[22,23] Our patient has extensive plexiform neurofibromatosis with bilateral renal-artery and superior-mesenteric-artery stenosis.

Sturge-Weber Syndrome *

Vascular nevi of the face, scalp, trunk, extremities, and leptomeninges characterize this syndrome. Sturge in 1879, Kalischer in 1897, Lannois-Bernoud in 1898, Parkes-Weber in 1922, Dimitri in 1923, and Krabbe in 1934 each contributed to the knowledge of the complete syndrome. It is congenital, possibly inherited as an irregular dominant character (Givner *et al.*) The facial component is noted at birth while the other features appear in infancy or early childhood.

The cutaneous angiomas are benign, may be telangiectatic or cavernous, have the color of a port-wine stain, and are not elevated. Unilateral facial lesions occur along the distribution of the trigeminal nerve. Conjunctivae, iris, and other parts of the eye and orbit may be involved. Occasionally angiomas extend into underlying fat, muscle, and bone. Postmortem findings in one case revealed similar lesions in the lungs, thymus, spleen, testes, lymph nodes, and pituitary gland (Givner *et al.*) The intracranial angiomas occur in the leptomeninges of the cerebral cortex. Minor foci may be found in the pia, within the underlying cerebral cortex, and in the subcortical medullary substance. Neurologic manifestations include contralateral hemiparesis, hemiatrophy, Jacksonian epilepsy, and mental retardation. Roentgenograms of the skull reveal calcified angioma or localized linear calcification that outlines the cerebral convolutions.

The vascular lesions apparently originate in early embryonic life. Differentation of this syndrome from other cerebral vascular malformations may be made by the presence of the port-wine-colored facial lesions. The prognosis relates to the size and location of the lesion. Successful therapy is limited to small cutaneous lesions. Roentgen therapy in deeper tissues is usually helpful.

Anesthesia

Some years ago a search was made of the records of the Pennsylvania Hospital to see if any account of the first use of ether could be found. The effort was unsuccessful, but Dr. James Darrach of Germantown, who had been resident physician in the hospital in 1846-1847 was still living. He said he could tell about a case which was one of the first, if not the first, in which ether was administered in the hospital. A man was brought in with a crushed leg, which Dr. George W. Norris was going to amputate. Dr. Norris told young Darrach to get some sulphuric ether, saying "We will try what they are doing up in Boston." Neither Dr. Norris nor Dr. Darrach had ever seen it used but young Darrach poured some on a towel and he bade the patient breathe it in.

In a few minutes the man became unconscious and very much alarmed, Darrach called out "Dr. Norris, the patient is unconscious!" Dr. Norris yelled back at him to "take that damned stuff away!"*

Congenital Diaphragmatic Herniae *

ROBERT R. THOMPSON, M.D.†

THE PATIENT, a full-term female infant, was the product of a normal and uneventful prenatal course in a 25-year-old primipara. (There was no history of drug use or rubella.) During the late second stage there was variability of fetal heart tones. The patient was delivered vaginally by means of outlet forceps.

Infant Examination and X-rays

The infant cried spontaneously. Its color was initially good. Within approximately a minute and a half spasticity was noted and a seizure was thought to occur, manifested by generalized rigidity and oculogyric crisis. When an attempt was made to palpate the heart, it was noted that this organ was displaced to the right. Dextrocardia was initially suspected. The patient was transferred to the newborn nursery isolette where a chest x-ray revealed a large mass of air-filled viscus occupying half of the left hemithorax (Figure 1). The diagnosis was eventration of the diaphragm. An umbilical vein catheter was inserted and sodium bicarbonate was administered intravenously. Also 100 percent oxygen was administered through an ambu bag, using a small amount of ventilatory pressure.

The infant was pronounced dead two hours and twenty minutes after delivery. The remainder of the physical examination revealed no other obvious congenital abnormality.

Necropsy Findings

At autopsy the body was a well-developed, full-term female infant weighing 2740 grams. Abnormal findings were confined to the pleural and peritoneal cavities. The dome of the liver was flush with the costal margins. The left leaf of the diaphragm was completely absent except for narrow ridges posteriorly and anteriorly (Figures 2 and 3). The left chest cavity was occupied by the stomach, pancreas, spleen and entire small bowel and all of the colon up to the splenic flexure. A small portion of the left lobe of the liver was also present in the left chest cavity. The heart was shifted into the right hemithorax;

†Department of Family Practice, Willmar Medical Center, Willmar, Minnesota. Presently a fellow in pathology, Mayo Clinic, Rochester, Minnesota.

*See editorial, page 45.

Fig. 1—X ray. Shows left hemithorax occupied by abdominal viscera in the case presented. Also shows mediastinal shift. Note the complete absence of aerated lung on the left. Taken 20 minutes after birth.

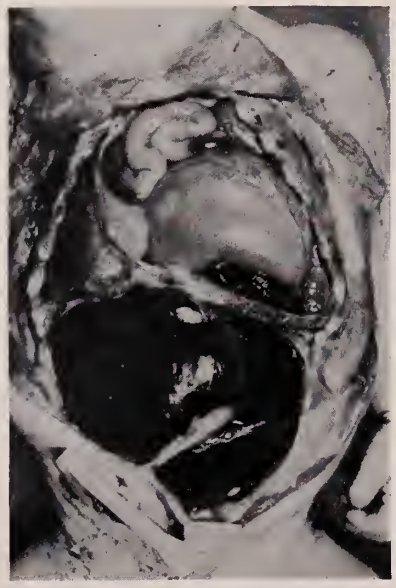

Fig. 2—Autopsy specimen. Shows left hemithorax occupied by abdominal viscera. Note early necrosis of the left lobe of the liver.

it weighed 14.5 gm. and was morphologically normal. The right lung weighed 14.5 gm., the left lung 2.5 gm. The tracheobronchial tree was clear and normal. The left lung was reduced in size to only a small bit of firm, meaty tissue and was completely airless. The right lung was generally atelectatic. The remainder of the organ examination revealed no abnormalities.

Bochdalek Diaphragmatic Hernia

In 1761 Morgagni described the pathology of diaphragmatic hernia;[15] but it was not until 1925 that the first review of the literature was written by Hedbloom. Hedbloom observed that 75% of infants with congenital diaphragmatic hernia died within the first month of life.[12] It was he who first advocated prompt surgical intervention in the treatment of this disorder. The mortality rate has dropped steadily from 78% in 1925 to 10% or less today. Early diagnosis and improved anesthetic techniques account for the improved survival rates.

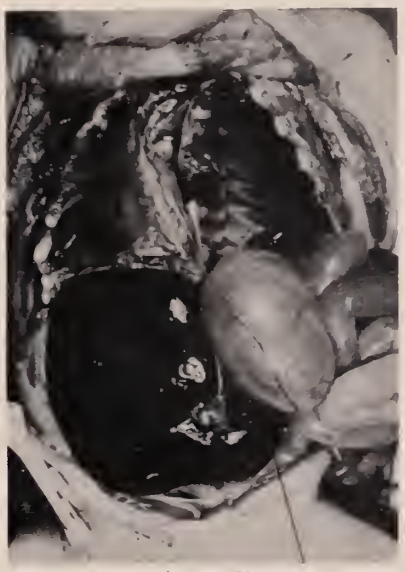

Fig. 3—Autopsy specimen. Shows narrow (rudimentary) leaf of the left diaphragm. Note hypoplastic left lung.

Embryology

Complete separation of the abdominal and chest cavities is a distinctly mammalian characteristic which allows the pleural space to attain the negative pressures necessary for respiration.

The intact diaphragm is a fibro-tendinous muscular organ which derives from two sources. Anteriorly it is formed by the septum transversum, which ultimately becomes the central tendon of the diaphragm. The lateral portions of the diaphragm are formed as the lung buds push dorsolaterally, invading the embryo body wall.[1] The failure of this membrane to unite with the muscular central portion is responsible for the patent pleuro-peritoneal canal or Foramen of Bochdalek.

Complete Agenesis Unlikely

The diaphragm is not a "paired organ" which developes in the midline, but a composite organ whose final structure is the result of a "bulldozing" process which goes on inside the peritoneal and pleural cavities. Therefore, complete agenesis of the diaphragm or of a hemi-diaphragm is un-

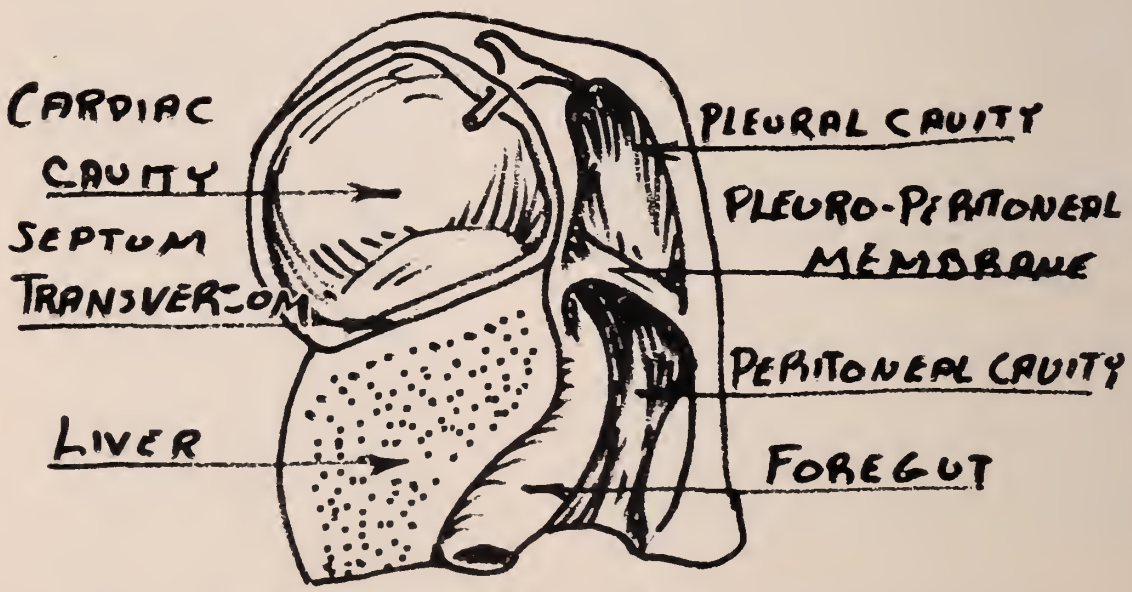

Fig. 4—Drawing. Taken (modified) from Arey. Shows seven-to-eight week embryo and depicts the pleuroperitoneal membrane through which herniae of Bochdalek occur. Shows the relation of this membrane to the septum transversum.

likely to occur. The central hemi-diaphragmatic defects are thus apt to be ones of degree rather than of kind.

Incidence

Adkins reports the incidence as one in every 2,000 births.[3] The left hemi-diaphragm, for reasons which are only speculative, is involved approximately four times as often as the right side.[2,1] For equally obscure reasons, there seems to be a slight preponderance of male babies afflicted.

Usually No Sac

If the abdominal viscera are pushed through the pleuroperitoneal foramen prior to its closure but after the pleural and peritoneal layers are formed, the hernia will have a true sac. Usually it does not.

Lung Truly Hypoplastic

The ipsilateral lung is truly hypoplastic, which undoubtedly contributes significantly to the mortality of this condition.[6]

Other Types of Concenital Diaphragmatic Herniae

The locations of the types of congenital diaphragmatic herniae are shown diagrammatically in Figure 5.

Esophageal Hiatal Hernia

This particular hernia, sometimes called *congenitally short esophagus,* represents the most common form of congenital diaphragmatic hernia. It occurs when the stomach is slow to descend into the abdominal cavity and is either trapped above the diaphragm, or enlarges the esophageal hiatus. Vomiting begins in the first two weeks of neonatal life, and in 50% of the cases, there is hematemesis and attendant anemia in 25% of the cases. Surgical correction is reserved for these patients who fail to respond to upright positioning and bland dieting.

Hernia of Morgagni

The Hernia of Morgagni comprises 3 to 5% of the congenital diaphragmatic hernia and occurs

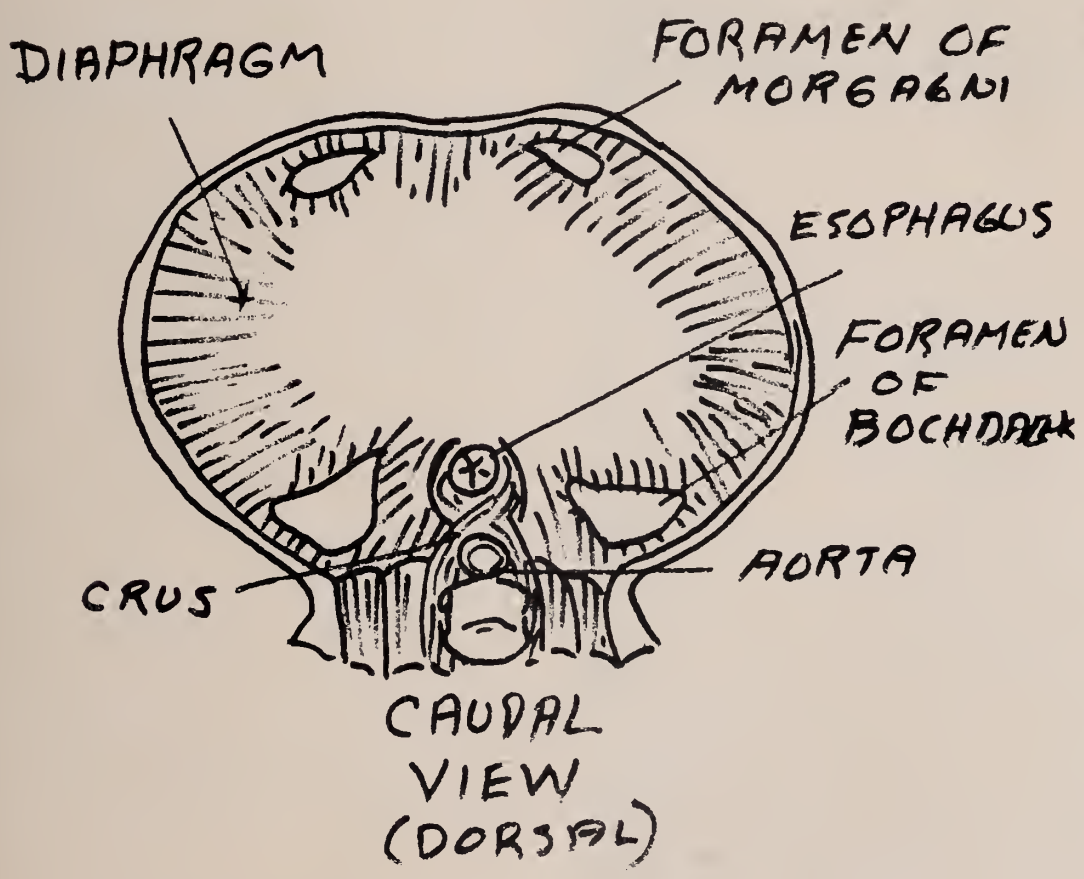

Fig. 5—Shows diagramatically the different locations of the types of diaphragmatic herniae from the under surface of the diaphragm.

Fig. 6—X ray. Barium swallow illustrates a thoracic stomach in a six week old infant who was asymptomatic.

Fig. 7—12-year-old asymptomatic patient showing eventration of the left hemidiaphragm.

through *Larrey's space,* the gap between the zyphoid and the coastal-diaphragmatic junction. Of all the congenital diaphragmatic herniae, it is most likely to remain asymptomatic until later life. The defect is easily approached surgically from an abdominal exploration when the preoperative diagnosis is well established.

Eventration of the Diaphragm

This anomaly does not represent a true hernia, but rather varying degrees of elevation of a thin leaf of a poorly reinforced hemi-diaphragm. Ventilatory distress may occur, but usually the condition is asymptomatic (Figure 6 and 7). X-rays reveal a smooth pleurodiaphragmatic interface with normal movement of the diaphragm.

The majority of patients are treated nonoperatively. Diaphragmatic imbrication of plication is the treatment where treatment is indicated. Occasionally differentiation from a Bochdalek hernia is crucial but difficult. Pneumoperitoneum, if time permits, may aid in the distinction.

Bochdalek Hernia

Symptoms of a foramen of Bochdalek hernia may be catastrophic in onset shortly after birth. They include dyspnea, cyanosis, and usually a scaphoid abdomen. Marked mediastinal shift may be mistaken for dextrocardia. Peristalsis over the chest cavity is an unreliable diagnostic sign.[3,2,6]

Early diagnosis and surgical correction of this condition are imperative. Loss of "right of domain" of the abdominal organs may prohibit layered closure of the abdominal wall until the skin and subcutaneous tissues have stretched, necessitating a two-stage closure.

Summary and Conclusion

The incidence of *all* types of congenital diaphragmatic hernia would seem to approximate one in 2,000 live and stillbirths. Respiratory distress, apnea, cyanosis, apparent dextrocardia, scaphoid abdomen and persistent vomiting are signs which should alert the clinician to the diagnostic possibility of a congenital diaphragmatic hernia, especially during the first 72 hours of life. Early surgical management of some types of symptomatic congenital diaphragmatic hernia may be imperative.

Duplication of the Duodenum

Presenting as an Adrenal Tumor

DAVID J. DUNLAP, M.D.,* JAMES M. MILLER, M.D., ROBERT G. McCANDLESS, M.D.

DUPLICATIONS OF THE small bowel occur most frequently in the ileum and almost always near the mesenteric border.[1] Bremer has written a comprehensive paper which includes the many theories for the formation of intestinal duplications.[2] He feels that true duplications always contain all the tissue layers of the intestine. He further states that in cystic type duplications, the original type of mucosa may change and resemble gastric mucosa or may be partially destroyed by internal pressure. Jalenko reported a case of duodenal duplication in which parietal cells were found in the specimen.[3]

In 1966 Houston and Lynn found less than 30 cases of duodenal duplications reported in the literature.[4] Gross has reported one case of duodenal duplication occurring on the antimesenteric side of the duodenum.[5]

Case Report

A thirteen-year-old boy was admitted to the Sandia Base Army Hospital on March 20, 1968, for evaluation of a right adrenal mass. He had been seen in the Urology Clinic at the Sandia Base Army Hospital because of enuresis. Other urinary symptomology included occasional urinary urgency and dark spots on his undershorts. An intravenous urogram had shown normal kidneys and ureters, but definite enlargement of the right adrenal shadow.

Physical examination revealed a normotensive male with no physical abnormalities. There was no palpable adrenal mass. The urinalysis, complete blood count, sedimentation rate, BUN, serum electrolytes, serum creatinine, creatinine clearance, urinary electrolytes, urine culture, urinary vanilmandelic acid, urinary 17-ketoid steroids, 17 ketogenic steroids, and pregnanetriol were normal. A voiding cystourethrogram was normal. On the 4.5-cm. cut a nephrotomogram showed a triangular-shaped right adrenal mass approximately 2.5 x 3 cm. in size. A percutaneous right femoral aortogram revealed normal renal vasculature and no vesesls in the area of the adrenal mass.

On March 21, 1968, both kidneys and adrenal glands were explored transperitoneally through a cheveron-type incision. The left colon was reflected and the left kidney and adrenal were normal. The right colon was reflected medially; the right kidney was normal but there was a 3.2 x 2 x 2-cm. mass in the areas of the right adrenal gland with a smaller nodule slightly medial to this, measuring approximately 0.5 cm. in diameter. The smaller mass was loosely adherent to the second portion of the duodenum, with numerous fibrous adhesions to the undersurface of the liver. The entire tumor mass was dissected free and removed. There was no communication with the duodenal lumen.

Gross pathological examination of the removed specimen showed two cystic structures which contained viscous chocolate-colored fluid and inspissated and calcareous debris.

Microscopic sections revealed multiple portions of normal-appearing adrenal cortex, fibrous tissue, hemorrhage and calcification. Also included were sections showing a complete gastrointestinal wall with the mucosa resembling small intestinal mucosa but containing large numbers of parietal cells. The specimen was examined at the 4th U.S. Army Medical Laboratory at Fort Sam Houston, Texas, and at the Armed Forces Institute of Pathology, Washington, D.C.

Discussion

Cysts of the adrenal gland usually are pseudocysts resulting from cystic degeneration and may contain blood and calcareous debris.[6] A duplication of the duodenum presenting as an adrenal tumor is an unusual entity, but certainly possible considering the proximity of the right adrenal gland and the second portion of the duodenum. Because of the presence of all layers of the bowel wall in this case, a true duplication must be considered. Both antimesenteric duodenal duplications and the presence of parietal cells in small bowel duplications have been previously reported.

*Sandia Base Army Hospital, Albuquerque, New Mexico. Now practicing urology in Minneapolis, Minnesota.

Summary

A case is reported of a 13-year-old boy with a mass in the area of the right adrenal gland. This mass was presumed to be a duplication of the duodenum invading the adrenal gland.

CAMPBELL'S SOUPS IN DIABETIC DIETS*

RECOMMENDATIONS FOR PLACING CAMPBELL'S SOUPS* INTO EXCHANGE LISTS

* These recommendations are based on a *one cup portion* when prepared according to directions on the label. If milk is used in the preparation, use part of your daily requirement.

Exchange Substitution for 1 Bread and ½ Fat	Exchange Substitution for 1 Meat and 1½ Bread
Tomato	Hot Dog Bean
Tomato, Bisque of	Split Pea with Ham
Tomato Rice, Old Fashioned	
Exchange Substitution for ½ Bread and ½ Fat	**Exchange Substitution for ¼ Meat and ½ Bread**
Asparagus, Cream of	Chicken Gumbo
	Chicken Noodle

Campbell's Soups are appetizing and enjoyable and, because of the many varieties available, offer your diabetic patients the opportunity to plan and enjoy more interesting and appealing meals.

*To obtain copies of "Recommendations for Placing Campbell's Soups Into Exchange Lists," suitable for distribution to patients, write to Campbell Soup Company, Dept. 500, Campbell Place, Camden, N.J. 08101.

There's a soup for almost every patient and diet ..for every meal and, it's made by Campbell

When diarrhea wrings the wedding belle...

It's all very well to counsel patience in diarrhea patients. There are times when relief of symptoms can't come too soon.

X-ray studies[1] in 16 normal subjects showed just how promptly the active ingredient in Lomotil does its work.

Lomotil retarded gastrointestinal motility particularly during the first three hours after administration. It continued its moderating action on the bowel for at least three hours more.

Physicians prescribe Lomotil more often than any other drug when the urgency for the control of diarrhea is most distressing.

1. Demeulenaere, L.: Action du R 1132 sur le transit gastro-intestinal, Acta gastroent. Belg. 21:674-680 (Sept.-Oct.) 1958.

Lomotil®

TABLETS/LIQUID

Each tablet and each 5 cc. of liquid contain:
Diphenoxylate hydrochloride . . . 2.5 mg.
(Warning: may be habit-forming)
Atropine sulfate . . . . . 0.025 mg.

Saves the Day

Warnings: Lomotil should be used with caution in patients taking barbiturates and, if not contraindicated, in patients with cirrhosis, advanced liver disease or impaired liver function.

Precautions: Lomotil is classified as a Schedule V substance by Federal Law with theoretically possible addictive potential at high dosage; this is not ordinarily a clinical problem. Use Lomotil with considerable caution in patients receiving addicting drugs. Recommended dosages

should not be exceeded, and medication should be kept out of reach of children. Signs of accidental overdosage may include severe respiratory depression, flushing, lethargy or coma, hypotonic reflexes, nystagmus, pinpoint pupils, tachycardia; continuous observation is necessary. The subtherapeutic amount of atropine sulfate is added to discourage deliberate overdosage.

Adverse Reactions: Side effects reported with Lomotil therapy include nausea, sedation, dizziness, vomiting, pruritus, restlessness, abdominal discomfort, headache, angioneurotic edema, giant urticaria, lethargy, anorexia, numbness of the extremities, atropine effects, swelling of the gums, euphoria, depression and malaise.

Overdosage: The medication should be kept out of reach of children since accidental overdosage may cause severe, even fatal, respiratory depression.

Dosage: The recommended average initial daily dosages, given in divided doses until diarrhea is controlled, are as follows:

Children:

3-6 mo....½ tsp.* t.i.d. (3 mg.)
6-12 mo...½ tsp. q.i.d. (4 mg.)
1-2 yr.....½ tsp. 5 times daily (5 mg.)
2-5 yr.....1 tsp. t.i.d. (6 mg.)
5-8 yr.....1 tsp. q.i.d. (8 mg.)
8-12 yr....1 tsp. 5 times daily (10 mg.)
Adults:....2 tsp. 5 times daily (20 mg.)
or 2 tablets q.i.d.

*Based on 4 cc. per teaspoonful.

Use of Lomotil is not recommended in infants less than 3 months of age.

Maintenance dosage may be as low as one-fourth the initial daily dosage.

The New Editor Appreciates the Old

A NEW EDITOR of an old journal should look backward before leaping ahead into the uncharted future. Although MINNESOTA MEDICINE existed in bulletin form and as a supplement to other publications in the late nineteenth and early twentieth centuries, its birth as an independent journal can be fixed as of January, 1918, when Volume One Number One was published under the editorial direction of Dr. Carl Drake. For three and a half decades he continued as editor to be succeeded by Arthur Wells, the great pathologist of Duluth. Then in 1961, Dr. Carl Rice was named editor-in-chief. Thus in 53 years MINNESOTA MEDICINE has been under the direction of three men.

As the incoming editor my first duty, a pleasant one, is to pay tribute to Carl Rice, who now becomes, with this issue, Editor Emeritus. MINNESOTA MEDICINE under his able direction has become recognized as an outstanding state medical journal, the winner of many awards for excellence. He has earned the thanks of the medical community and of the state for a superior performance over the last 11 years, his term as editor-in-chief. I will not attempt to assess his work now. A proper appreciation of Carl Rice's contributions will be set forth in a later issue. As editor he has set high standards for others to follow. The Editorial Board's first objective is to find what other physicians around the state would like to join the Board and take part in the exciting venture of publishing MINNESOTA MEDICINE and the editor would like to hear from such interested people.

As Carl Rice has frequently stated, MINNESOTA MEDICINE can be a great medical journal. Minnesota is known as an outstanding medical center. Its medical school in Minneapolis and the Mayo Clinic in Rochester are acclaimed throughout the civilized world. Minnesota's other medical schools soon to open in Rochester and Duluth are surely destined for greatness. In our state in practically every field of medicine can be found world-renowned experts. But the pages of MINNESOTA MEDICINE are not only open to the experts but to every physician who wishes to address this audience. The editor appeals to the readers for contributions, for articles, case reports, and letters.

Your new editor is no stranger to this masthead having been put there on Carl Rice's recommendation in 1961. The average tenure of the first three editors was 17⅔ years. To meet this average I would have to live to be an octogenarian.

The White Doctor—Black Patient Relationship

It is my contention that in the diagnosis and treatment of the ills of-the-black-patient-the-white-doctor often fall short of the high level of competence that he usually achieves in treating his white patients. This is, of course, a generalization, and unquestionably there are many notable exceptions. Nevertheless, if the premise is true, it is something that we in the medical profession should try to correct.

Let us assume that there are some markedly prejudiced white physicians who come into contact with black patients and frankly give them second-rate treatment. Although in this geographic area I feel the number of physicians who would do this is small, this group should be mentioned only to be condemned. On the other hand, there are many physicians who might even go the extra mile, so to speak, with their black patients if it were not for several mitigating factors that come into play, and it is to these I would like to address myself.

The problem of communication so necessary to the establishment of a good patient-doctor relationship may be hampered by a lack of comprehension on the doctor's part. He simply doesn't understand or misunderstands the patient's complaint, because of a language barrier. The idioms of black culture are often unknown to him, and thus he may miss the subtle or not so subtle [tip off] to the crux of the matter. Hence, he fails to diagnose the case in his usual efficient manner, and at the very least, subsequent visits and more cost will be required in order to pinpoint the problem. At the worst the problem will go undiagnosed. On the other hand, the patient may not understand the doctor's question, and his answer could well be completely opposite to the actual facts. Thus the doctor will be thrown off track. Either the doctor, or his patient, or both, might realize their lack of understanding but not want to admit it—for the same reason, false pride or vanity.

The second problem that may exist is a lack of rapport between the two. Although this exists in the white-white situation, it undoubtedly is more prevalent in the white-black situation. Is it a lack of trust in each other? Is it disrespect for the other's race? Is it that each suspects the other of "putting one over on him?" For whatever the reason, if the lack of rapport exists, only the most superficial of problems will be adequately dealt with, and the experience will only serve to make future confrontations more difficult. If an uncomfortable relationship exists between the doctor and his patient, each may subconsciously leap to accept the superficial problem with its solution as a completion of their contract with each other. Hence, the deep problem, perhaps the life endangering problem, goes unsolved and untreated.

I have not mentioned the openly hostile black, because I think it takes only the most dire of circumstances for him or her to come to see a white doctor in the first place. In all but the purely mechanical parts of medicine mutual respect for each other is a must for a satisfactory patient-doctor relationship to exist. The doctor cannot assume all fault in this unhappy situation should second-rate treatment result.

There are several steps a physician could take to help rectify an inequality in his practice: First, help his black patients feel more at home by having at least a few copies of black literature in his reading rack and perhaps an object or two of black art in his waiting room or office. Second, the distribution of a booklet to patients with common phrases used by physicians and what they really mean. Both white or black patients might benefit by this clarification of terms. A third helpful step might be to openly admit to the patient that I, as his doctor, cannot really understand what is going on and admit that it may be my own fault. This is hard to do sometimes especially when we are rushed for time or uncomfortable in our relationship. Fourth, ask our black physicians in this area to discuss the matter with us in a lecture or in a group discussion.

Finally I think that both we as white physicians and the blacks as patients should admit that we are simply not as comfortable with each other as we should or could be. It will take an open line of communication between each other if we are to break down some of these barriers. Great relationships can only exist where there is honesty, openness, and trust between participants, and I just doubt if this commonly exists between the

white doctor and his black patient. It is my feeling as a white physician that it is a very special privilege and responsibility for me to take care of a black patient. I realize that although I might wish to cast off all racial predjudices one just dues not shed his past experiences; they are there and they always will be there. It is only with the making of new and enlightening experiences that the old will cease to have an effect on my actions. I think we should welcome the challenge of the white doctor-black patient confrontation and work to make it a satisfying experience for both.

Diaphragmatic Hernia*

DIAPHRAGMATIC HERNIA represents the most urgent surgical emergency of the newborn. Anoxia and respiratory acidosis develop rapidly and may lead to a fatal outcome in a remarkably short period of time.

Early detection is obviously essential to survival but, in the Mayo Clinic's experience, the fatal cases have been largely in the group diagnosed and operated upon within six to eight hours of birth. Obviously there are many factors at work which are beyond the physician's control. Early examination may be combined with early treatment even before a diagnosis is made.

Administration of oxygen, insertion of a nasogastric tube to delay gaseous distention, and providing a warm, humid environment (Isolette) are the most immediate needs. Gentle respiratory support by means of an endotracheal tube is the next consideration. The intravenous administration of sodium bicarbonate is an essential step in combatting the developing acidosis. However, this alone will not adequately correct the acidosis and certainly will not save the infant who develops distress early.

Surgery must be as immediate as possible. Opening the abdomen and relieving the pressure of the abdominal viscera against the lung and mediastinum is the indicated treatment. Once this has been accomplished the patient may show remarkable improvement. No attempt should be made to fully expand the ipsolateral lung. Hypoplasia and atelectasis respond better to slower and more gentle expansion.

In the event that the patient's condition is still precarious and the abdominal tension seems too great on closure, the use of Silastic-backed Teflon to create a ventral hernia or "silo" is a most effective way of temporizing.

Early diagnosis and immediate surgery offer the only chance for survival of these critical cases.

Hugh B. Lynn, M.D.†

Reminder

119th Annual Meeting of the Minnesota State Medical Association in Rochester, Minnesota, May 18, 19 and 20, 1972.

The teenager today lives in a mighty confusing world. Half the grownups are telling him to find himself while the other half tell him to get lost.

Polymyalgia Rheumatica

THE REPORT, "Polymyalgia Rheumatica" by Molldrem and Olin* is noted with particular interest because it again calls attention to the relationship of polymyalgia rheumatica to giant cell arteritis and the importance of early diagnosis and therapy of these conditions. It has been our experience that these syndromes will be found more frequently when the clinician is aware of the possibility of this condition. Involvement of the coronary arteries by giant cell arteritis also has been suspected by us. While very few cases have been demonstrated at autopsy, surgeons doing revascularization procedures of the myocardium can help establish this diagnosis by getting biopsy material when this condition is suspected.

It should be pointed out again that the temporal artery biopsy may be negative. Temporal arteritis is known to be patchy in "skip" areas so that a negative biopsy does not exclude the disease. The etiology of these syndromes remains unknown, but as immunological investigations are carried out, we may expect in the future to come closer to having this problem solved.

At the present, we should have a high index of suspicion, keeping in mind that this may be the diagnosis in patients over fifty-five years of age with girdle muscular pains, elevated sedimentation rates and with or without temporal arteritis. It should also be remembered that the natural course of the disease is from three to five years or longer and that therapy with steroids may have to be prolonged.

Cover Photograph

"Mount Fujiyama"

While attending the 1969 International Congress of Radiology in Japan, Dr. Harry W. Mixer took the cover photograph of Mount Fujiyama. He used ektachrome color film and took the shot of Fujiyama early in the morning. Dr. Mixer indicated that on the previous day the Mountain was completely obscured by clouds, but on the morning of the picture taking, the clouds had all disappeared and there Mount Fujiyama stood in all its majesty.

Mount Fujiyama located in south central Honshu is the highest mountain in Japan.

Dr. Mixer is a radiologist practicing in the Minneapolis area.

The surgeon now ordered his patient to be stripped to his shirt, and then entirely baring the arm, he began to stretch and examine it, in such a manner that the tortures he put him to caused Jones to make several wry faces; which the surgeon observing, greatly wondered at, crying, "What is the matter, sir? I am sure it is impossible I should hurt you." And then holding forth the broken arm, he began a long and very learned lecture of anatomy, in which simple and double fractures were most accurately considered; and the several ways in which Jones might have broken his arm were discussed, with proper annotations showing how many of these would have been better, and how many worse than the present case.*

*Henry Fielding: Tom Jones Book IV, Chapter XIV, 1749.

Letter to the Editor

Teenage Mothers

In the September issue of "Minnesota Medicine*" Doctor Eric Knox reported on a group of 120 girls, age 12 to 16 years, who were delivered of full-term pregnancies at Hennepin County General Hospital in the years 1968 and 1969. The author compared the complications in this group with the complication rate of all age groups and found that in the young teenager the risks were higher, the baby required more specialized attention, and there were more Cesarean sections, a higher incidence of toxemia, prolonged labor, premature delivery, and post partum hemorrhage. Twenty-five percent of the infants were placed in the high-risk nursery.

Of the 120 girls delivered in 1968 and 1969, 26% were married, but 96% of these marriages took place *after the pregnancy was diagnosed.* The author closes by pointing out three facts to his fellow pediatricians: (1) The young mothers are themselves pediatric patients, and as such, need specialized care; (2) 25% of the infants are in the high-risk group and perinatal mortality runs higher and (3) 75% of the mothers are keeping their children of which only 25% of these receive adequate care.

The article ends with a timid suggestion that "studies are needed to define the role of contraception in the professional approach to the teenage female."

The chilling truth is that probably 99% of these 120 pregnancies were *compulsory pregnancies,* forced upon individuals who are but children themselves. Only 26% got married. There is no follow-up given of the social results of these marriages, but the instability of early teenage marriages is an apparent social fact. Twelve percent of these girls received no prenatal care at all, probably because of shame, ignorance, or lack of funds.

The author never questioned the morality of allowing these children, still almost helpless in the jungles of our modern society, to go through the physical risks, discomfort, humiliation, and anguish of a compulsory pregnancy. He only examined the increased incidence of risks and suggested greater vigilance in the care of these patients.

I frequently see this age group in my own obstetrical practice. I have had to face them week after week in the office, watching them gradually become old before their time—hurt and disillusioned by the world around them—withdrawn from their contemporaries, yet not adults, watching the distortion of their young bodies before they themselves are fully grown.

And, in addition to guiding these young mothers through a high-risk pregnancy, I must deliver a child which will probably (75%) receive inadequate care!

One more point of concern to me is the fact that there were no therapeutic abortions performed at Hennepin County General Hospital for any reason during the two years in which this study was carried out, and it is almost a certainty that there were some cases of pregnancy from rape and incest during this period of time. Were they either included in this group of 120 girls, or were they turned away to seek help elsewhere?

A recent annual report from the Minnesota State Department of Public Welfare for 1970 includes 194 known cases of child abuse in 1970, 17 of which were cases of incest. Hennepin County was responsible for 37.1% of these cases. I am aware of two cases of incest in the past two months, both in 13-year-old girls—one impregnated by her 17-year-old brother and the other by a contrite father. Both girls were brought to St. Paul Ramsey County for help. Did Hennepin County General have no such cases in two years, or were such included in the group of 120?

I submit to you that this is an immoral situation. I would not force a daughter 16 years or less through a compulsory pregnancy, no matter what the circumstances of conception. And the same compassion should exist for the underprivileged.

Jane E. Hodgson, M.D.
St. Paul, Minnesota

Classified advertising rates are thirty (30) cents a word; minimum monthly charge $7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

ARE YOU TIRED OF THE SMOG, traffic congestion, sociological problems, crime and other irritations which have become part of today's urban living? Well then DISCOVER WATERTOWN, WISCONSIN. Exchange all the big city unpleasantries for the peaceful environment and easy going pace of a residential city. Watertown, a progressive community, is ideally located equi-distant between Milwaukee and Madison in southeastern Wisconsin's lake district. The community has a trade (and medical practice) area serving 40 - 50,000 people. Many new schools, parks, trees and recreational opportunities. A stable economy. Our new Community Health Care Center with its beautiful 110 bed general hospital, connecting (but separate) 24 unit Medical-Dental Office Building (choice of suites still available), and connecting 130 bed Nursing Home, was completed in the Spring of 1971. WE URGENTLY NEED another Internist, an Otolaryngologist, an Opthalmologist, Obstetrician-Gynecologists, and Family Practitioners to join existing medical staff. An immediate successful practice assured. Excellent rapport with the University of Wisconsin Medical School at Madison, and the Medical College of Wisconsin (formerly Marquette University School of Medicine) at Milwaukee. Medical Staff leading and supporting recruitment effort. Write or call Dr. Paul Glunz, Watertown Memorial Hospital, Watertown, Wis., 53094. Telephone 414-261-4210.

LOCUM TENENS WANTED for July and August 1972 in Northwest Wisconsin Resort Area Incorporated Practice. Pay $2,000 per month. Will welcome applicant for any other month. Permanent association could result. Send profile to Box 463 Classified Advertisements, c/o Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

PSYCHIATRIC RESIDENCIES—Excellent, approved psychiatric training; both demanding and clinically rich with a stimulating, well-balanced program. Affiliated with Michigan State University's College of Human Medicine. The setting is a culturally satifying community; the serene, scenic Grand Traverse Bay area. Three year plan: $12,215 to $13,885; five-year plan; $13,927 to $26,121. Contract Dr. Paul E. Kauffman, Director of Psychiatric Training, Room (166), Traverse City State Hospital, Traverse City, Michigan 49684. Phone (616) 947-5550. An equal opportunity employer.

ANESTHESIOLOGIST WANTED to join a group of two in an expanding hospital in North Suburban Mpls. Write or phone A. M. MarCia, M.D., 9200 W. Bush Lake Rd., Mpls., Mn. 55431. Call after 6:00 p.m. 944-1444.

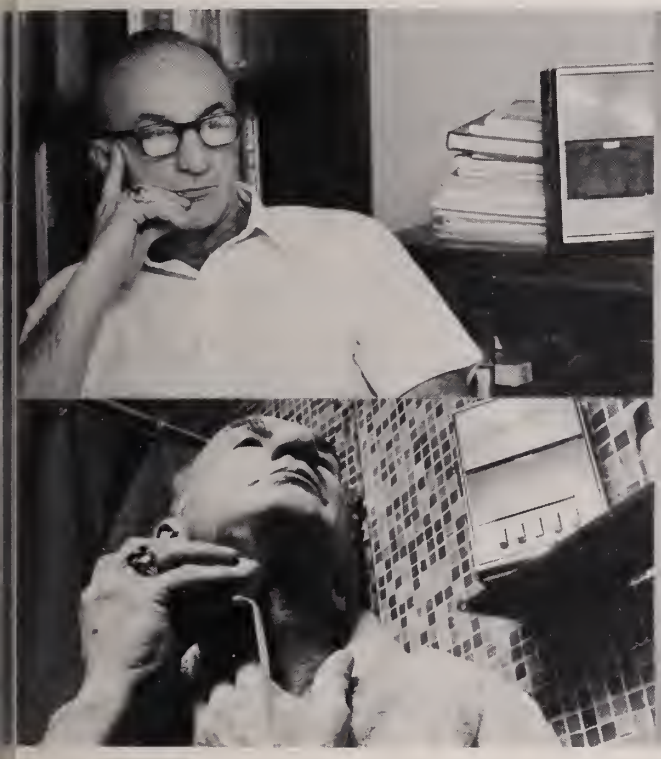
ONE OR TWO PHYSICIANS wanted to take over practice in Osseo, Minnesota. Finest facilities. Finest hospital facilities. T. J. Bloedel, Osseo 55369. Call (612) 425-2117.

WANTED NOW: General Practitioner and a Surgeon to join our three-doctor Clinic in Northwest Wisconsin Resort, Forest and Retirement Area Town of 2,400 with a patient population of 25,000. Fully equipped modern Clinic building, with new accredited 50-bed Hospital and 50-bed extended care nursing home. Deer, ducks, partridge and fish 5 minutes away. Generous salary commensurate with training and experience the first year, then full partnership. Brochure with maps and photos upon request. Call collect or write L. J. Olson, M. D., Spooner Clinic Ltd., Spooner, Wisconsin 54801, telephone 715-635-2151.

AVAILABLE—Young married G.P. with some surgical experience. Deferment not needed. Write Minnesota Medicine, 462, 375 Jackson St., St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER wanted to take over busy and well established practice. Good nearby hospitals. Little or no capital investment. Excellent office facilities. Write or call A. M. Jensen M.D., Telephones: Office (612) 328-5223, Res. 328-4428. Brownton, Minnesota 55312.



ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

GENERAL PRACTITIONER to join young 5 man family practice group. College town of 7,000 serving approximately 20,000 population. Accredited hospital with specialist consulting staff. 30 miles from St. Paul-Minneapolis, Minnesota. Contact J. C. Palmquist, M.D., River Falls Medical Clinic, River Falls, Wisconsin 54022. Phone (715)-425-5322.

Audio News Journal Now Has More Scientific News

At a New, Low Price of $40.00 a Year.

AMA's Audio News Journal now brings you more scientific news in response to physician requests.

Coverage of scientific news on treatments, techniques and drugs has been increased. Major medical magazines are read and reviewed; vital information is passed on to you, thus saving your valuable time.

Interviews with leading speakers at medical conventions and scientific exhibitors bring you the latest research findings, techniques and developments.

Enter your subscription to Audio News Journal for the next twelve months. It costs only $3.33 a month for 60 minutes of information keeping you current on the fast changing world of medical practice.

When you select this familiar antibiotic for IV infusion you have available a broad dosage range that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

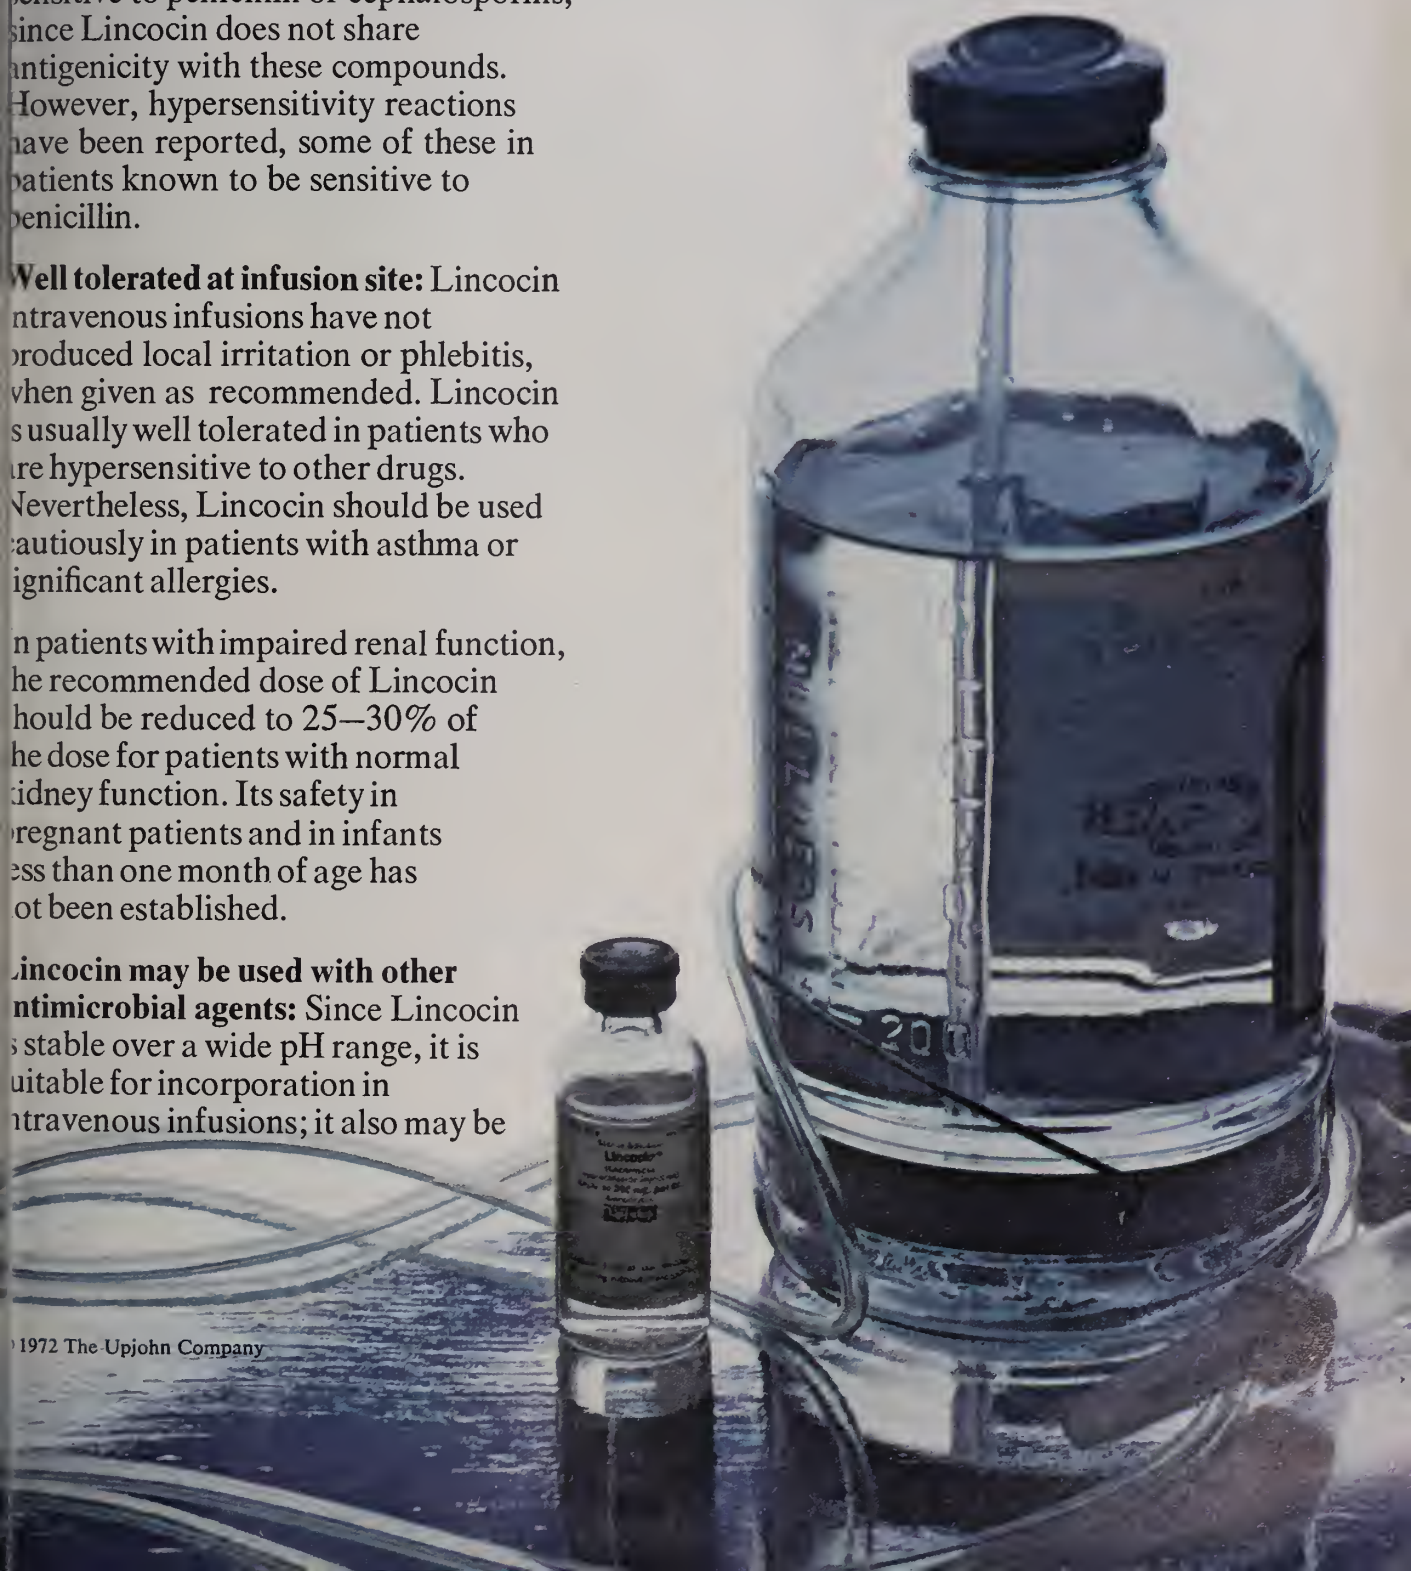
In usual IV doses, Lincocin (lincomycin hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water. But when 4 grams or more per day is given, Lincocin should be diluted in not less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

infections caused by susceptible strains of pneumococci, streptococci, and staphylococci, including penicillin-resistant strains. Staphylococcal strains resistant to Lincocin (lincomycin hydrochloride, Upjohn) have been recovered. Before initiating therapy, culture and susceptibility studies should be performed. Lincocin has proved valuable in treating patients hypersensitive to penicillin or cephalosporins, since Lincocin does not share antigenicity with these compounds. However, hypersensitivity reactions have been reported, some of these in patients known to be sensitive to penicillin.

Well tolerated at infusion site: Lincocin intravenous infusions have not produced local irritation or phlebitis, when given as recommended. Lincocin is usually well tolerated in patients who are hypersensitive to other drugs. Nevertheless, Lincocin should be used cautiously in patients with asthma or significant allergies.

In patients with impaired renal function, the recommended dose of Lincocin should be reduced to 25—30% of the dose for patients with normal kidney function. Its safety in pregnant patients and in infants less than one month of age has not been established.



Lincocin may be used with other antimicrobial agents: Since Lincocin is stable over a wide pH range, it is suitable for incorporation in intravenous infusions; it also may be administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

© 1972 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn)

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatmen *Skin and mucous membranes*—Skin rashe urticaria, vaginitis, and rare instances of e foliative and vesiculobullous dermatitis hav been reported. *Liver*—Although no direct r lationship to liver dysfunction is establishe jaundice and abnormal liver function tes (particularly serum transaminase) have bee observed in a few instances. *Cardiovascul* —Instances of hypotension following pare teral administration have been reporte particularly after too rapid IV administra tion. Rare instances of cardiopulmonary a rest have been reported after too rapid I administration. If 4.0 grams or more admi istered IV, dilute in 500 ml of fluid an administer no faster than 100 ml per hou *Special senses*—Tinnitus and vertigo hav been reported occasionally. *Local reactio* —Excellent local tolerance demonstrated t intramuscularly administered Lincoci (lincomycin hydrochloride). Reports of pa following injection have been infrequen Intravenous administration of Lincocin 250 to 500 ml of 5% glucose in distille water or normal saline has produced n local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500 m* Capsules—bottles of 24 and 100. *Steril Solution, 300 mg per ml*—2 and 10 ml vial and 2 ml syringe. *Syrup, 250 mg per 5 m* —60 ml and pint bottles.

For additional product information, consu the package insert or see your Upjoh representative.

Laboratory Medicine

Hepatitis Associated (Australia) Antigen

JEFFREY McCULLOUGH, M.D.* AND HERBERT F. POLESKY, M.D.†

In 1964, Blumberg[1] found a new antigen when studying sera from multitransfused patients for isoprecipitins against lipoproteins. Since an antibody present in the serum of two hemophiliacs reacted with the nonlipoprotein antigen in serum from an Australia aborigine, he and his coworkers[2] called it the Australian antigen. Subsequently, the antigen was found in patients with mongolism, leukemia, leprosy and most recently polyarteritis nodosa[3,4,5]. An association between Australia antigen and hepatitis became apparent when a previously negative patient with Downs syndrome developed Australia antigen positivity concurrent with hepatitis.[5] Studies too numerous to review here confirmed the association of Australia antigen with hepatitis and resulted in its being renamed the hepatitis-associated antigen.

In addition to widespread publicity of studies of hepatitis-associated antigen, hepatitis has been mentioned frequently in the press because of the epidemiologic reports on the increased incidence in individuals between 15-30 years of age and its association with drug usage.[6] Further publicity has resulted from recent court decisions in cases of transfusion associated hepatitis that have accepted the doctrine of strict liability[7] and applied the concept of implied warranty to services.[8] Thus it seems appropriate to review current knowledge of the hepatitis-associated antigen and to present data on its incidence in Minnesota blood donors.

Characteristics of the Antigen

Although the exact nature of the antigen and its relationship to hepatitis is unsettled, present concepts are as follows:

Hepatitis-associated antigen is a virus-like particle. Evidence for this includes: (a) its appearance by electron microscopy;[9] (b) the presence of small amounts of RNA[10] and RNA dependent DNA polymerase activity[11] in isolated preparations of antigen and (c) the detection of hepatitis-associated antigen by fluorescent antibody in the nuclei of liver cells of patients with hepatitis.[12] Evidence against its being a virus includes failure to obtain growth in tissue culture and the fact that hepatitis-associated antigen is not present in cord blood of infants whose mothers are hepatitis-associated antigen positive.[13]

According to the National Research Council[14] "the detection of hepatitis-associated antigen in a person's serum is a specific indication that the person is infected with one of the causative agents of human viral hepatitis." Supporting studies include Giles et al.[15] who found a 95% incidence of hepatitis-associated antigen in (MS-2) long incubation hepatitis and 0% incidence in (MS-1) short incubation hepatitis. The frequency of hepatitis-associated antigen positivity[16] is generally greater in parenterally acquired hepatitis (13-95%) than cases considered infectious (0-47%). *The variability and overlap of these figures should be kept in mind when hepatitis-associated antigen is used as a diagnostic test.*

Role in Etiology of Acute Hepatitis

The etiologic role of hepatitis-associated antigen in serum hepatitis is also supported by transfusion studies. Gocke et al.[17] reported that nine of twelve recipients of hepatitis-associated antigen positive blood developed hepatitis and seven of these patients became hepatitis-associated antigen positive; however, subsequent studies indicate that the hepatitis risk of hepatitis-associated antigen positive blood may be 50%[18] or lower.[19] The incidence of hepatitis among recipients of hepatitis-associated antigen postive blood is three to five times that of recipients of blood negative for hepatitis-associated antigen[14] and hepatitis-associated antigen is 85 times more common in blood donors implicated in hepatitis transmission than in normal controls.[20] In cases of transfusion associated hepatitis in Minneapolis, six of thirteen (46%) recipients developed a positive test for hepatitis-associated antigen: however, only one of the 171 (0.59%) tested implicated donors was hepatitis-

*Assistant Professor Laboratory Medcine; Director, Blood Bank, University of Minnesota Hospitals; Medical Director, St. Paul Regional Red Cross Blood Center.
†Director, Minneapolis War Memorial Blood Bank; Assistant Professor Laboratory Medicine, University of Minnesota.

associated antigen positive when tested retrospectively. Taswell et al.[20] have shown an excellent correlation between the incidence of hepatitis-associated antigen in the donor population and the frequency of transfusion-associated hepatitis. This seems to hold for Minneapolis where hepatitis occurs in 1/1670 recipients and 1/1610 donors is hepatitis-associated antigen positive (Table 1).[21]

TABLE 1

Hepatitis-Associated Antigen Testing on Patient Specimens*

Diagnosis	# tested	# positive	%	# with antibody
Hepatitis	151	57	(37.7)	0
Possible hepatitis	76	6	(7.9)	0
Close contact with hepatitis	40	3	(7.5)	0
Patients on Methadone	56	2	(3.6)	1
Specimens submitted without a diagnosis	342	39	(11.7)	1
Other†	100	0		2

*Specimens sent to the Minneapolis War Memorial Blood Bank for hepatitis-associated antigen testing. To enhance sensitivity specimens were concentrated with lyphogel.
†Hospitalized patients with miscellaneous diagnosis.

The appearance of hepatitis-associated antigen in a patient's serum is usually transitory and may occur up to four weeks prior to clinical or laboratory evidence of liver disease.[16] Hepatitis-associated antigen usually disappears before symptomatic or liver function recovery. From 18-35% of hepatitis-associated antigen positive patients have remained hepatitis-associated antigen positive after 24 months, and it appears that chronic hepatitis-associated antigen positivily occurs more commonly following mild or subclinical hepatitis. Thus, the "carrier" may be unaware of preceding illness, an important point in blood donor screening.

In acute hepatitis, hepatitis-associated antigen testing identifies patients with "hepatitis-associated antigen positive hepatitis" (Table 1). A positive test suggests a viral etiology, infection by parenteral transmission (though large doses of orally administered MS-2 can cause hepatitis-associated antigen positive hepatitis)[15] and a more prolonged hospital course. Such patients should be cared for with isolation techniques. A negative test for hepatitis-associated antigen does not rule out viral hepatitis. Patients developing hepatitis in point source epidemics have been uniformly hepatitis-associated antigen negative. In classical short incubation (infectious) hepatitis, hepatitis-associated antigen is usually not present though other virus-like particles have been observed.[22] *Because of the lack of sensitivity of present methods and the transient presence of hepatitis-associated antigen, many cases of serum hepatitis will be hepatitis-associated antigen negative.*

Relationship to Chronic Liver Disease

The status of hepatitis-associated antigen in chronic liver disease is somewhat less clear. Wright[23] reported that 50% of patients with "unresolved classic hepatitis" were hepatitis-associated antigen positive, and Fox[24] found 40% of seven patients with "prolonged viral hepatitis" to be hepatitis-associated antigen positive. Other forms of chronic active hepatitis have a much lower rate of occurrence of hepatitis-associated antigen and cirrhosis (including crytogenic, inactive post-necrotic and biliary) is usually hepatitis-associated antigen negative. A few cases of hepatoma have been reported to be hepatitis-associated antigen positive.[25] Thus, in chronic active hepatitis, hepatitis-associated antigen testing appears to differentiate between two groups, a "hepatitis-associated antigen positive group that most likely progressed from acute viral hepatitis, and the lupus erythematosis positive, hepatitis-associated antigen negative group that probably represents an immunologic aberation."[16]

Antibody Studies

Antibody to hepatitis-associated antigen when detectable, occurs about four to five weeks after transfusion of infectious plasma although we have found it transiently in blood donors with no known exposure to or history of hepatitis. Antibodies to hepatitis-associated antigen have been found in very few patients with acute or chronic hepatitis but occur commonly in hemophiliacs. The danger of transfusing blood containing antibody to hepatitis-associated antigen is not known.

Testing Methods

The most commonly used methods of testing for (immunodiffusion) hepatitis-associated antigen are agar gel diffusion and counterelectrophoresis (immunoelectroosmophoresis). Complement fixation, hemagglutination inhibition and radioimmunoassay are performed in certain research laboratories, but the National Academy of Sciences has recommended that they not be adopted for routine use at present.[26] The relative sensitivity of these methods when comparing titers is agar gel diffusion 1, agar gel diffusion using concentrated serum 5, counterelectrophoresis 5-15, complement fixation 100-

200, hemagglutination inhibition 100-200, and radioimmunoassay 100-200.[16] These figures can be misleading; however as they refer to *titers,* and comparable increases in patient or blood donor positivity are not found. For instance, Thulstrup[27] showed that in 32 patients with serum hepatitis, counterelectrophoresis increased the number of positive specimens 31% over agar gel diffusion, however, the number of patients with a positive test was increased only 3%. Gocke[18] found that counterelectrophoresis increased the number of hepatitis-associated antigen positive blood donors only to 18/3855 as compared with 17/3855 detected by agar gel difussion. Prince[25] found very little increased patient yield of hepatitis-associated antigen in cases of acute and chronic liver disease using counterelectrophoresis compared with agar del diffusion.

Experience in Minnesota

Since early 1970 investigation of hepatitis-associated antigen and blood donor testing has been performed in some Minnesota centers, notably Minneapolis War Memorial Blood Bank, University Hospital and the Mayo Clinic. Most of the testing was performed by agar gel diffusion using as antisera raw plasma or serum obtained from persons (usually hemophiliacs) who had the antibody to hepatitis-associated antigen. In January 1971 a standard antiserum was made available to all state health departments so that hepatitis-associated antigen testing of blood donors could be encouraged. Through the joint efforts of the Minnesota Department of Health, the Minnesota Medical Association (Committee on Blood and Blood Banks) and the Minnesota Association of Blood Banks, this antiserum was distributed to large blood centers in the state for routine testing of donors. Since that time, commercial reagents have been licensed for sale. Thus, contrary to one report,[28] Minnesota blood banks have been involved in hepatitis-associated antigen testing for quite some time and expanded this testing quickly and effectively when reagents became available.

The incidence of hepatitis-associated antigen positive blood donors in Minnesota is now well established and is quite low (Table 2). At this writing, all blood collected by Minneapolis War Memorial Blood Bank, St. Paul Regional Red Cross, Mayo Clinic and University of Minnesota is tested for hepatitis-associated antigen. Physicians should be aware that some centers use the agar gel diffusion method which requires 24 hours for hepatitis-associated antigen testing, thus testing of fresh products such as fresh whole blood or platelets may not be completed prior to transfusion.

TABLE 2

Results of Hepatitis-Associated Antigen Testing of Blood Donors from Different Centers Using Agar Gel Diffusion (AGD) and Counterelectrophoresis (CEP) Methods

Blood Donors	Test Method	Number Tested*	Number Positive	Percent Positive
University of Minnesota	AGD	11,138	11	.098

Conclusions

Hepatitis-associated antigen testing is a valuable addition to pretransfusion testing of blood, but the test has significant limitations. Therefore, efforts to reduce transfusion-associated hepatitis should include not only hepatitis-associated antigen testing but also continued emphasis on thorough evaluation of the blood donor's medical history and the use of blood collected from volunteers. The most important step to decrease the hepatitis risk is judicious use of blood and blood components.

ASSISTANT MEDICAL DIRECTOR—We're looking for a physician under age 40, man or woman, who will appreciate working in a pleasant environment and one of the best locations in the nation to raise a family. We prefer at least two years of private practice; may be internist, surgeon, psychiatrist or general practitioner. This career position on our medical team includes good hours and liberal vacation and benefit program. Salary is negotiable. If interested write to our Medical Director: Fred Dinkler, M.D., The Bankers Life, 711 High Street, Des Moines, Iowa 50307.

WANTED NOW: General Surgeon to practice with 10 man group in Hibbing, Minnesota. Great area for one interested in hunting, fishing, snowmobiling, skiing, or any out of door living. Superior schools, junior college. Modern clinic building but two blocks from excellent hospital facilities. Patient area of 50,000. Compatible staff. Call collect or write to: John J. Muller, M.D. or O. A. Seavey, Administrator, Adams Clinic, P. A., Hibbing, Minnesota 55746. Telephone: 218-262-3425.

WANTED—Doctor to share office space in new area. Any speciality or practice acceptable. Roseville Professional Center, 645-4233.

PFIZERPEN® VK
(POTASSIUM PHENOXYMETHYL PENICILLIN)

ACTIONS: *Microbiology:* Phenoxymethyl penicillin exerts high in vitro activity against staphylococci (except penicillinase-producing strains), streptococci (groups A, C, G, H, L, and M) and pneumococci. Other organisms sensitive to phenoxymethyl penicillin are *Corynebacterium diphtheriae, Bacillus anthracis, Clostridia, Actinomyces bovis, Streptobacillus moniliformis, Listeria monocytogenes,* Leptospira, and *Neisseria gonorrhoeae. Treponema pallidum* is extremely sensitive. *Pharmacology:* Phenoxymethyl penicillin is more resistant to inactivation by gastric acid than penicillin G. It may be given with meals and average blood levels are two to five times higher than the levels following the same dose of oral penicillin G. Once absorbed, phenoxymethyl penicillin is about 80% bound to serum protein. Tissue levels are highest in the kidneys, with lesser amounts in the liver, skin, and intestines and small amounts in all other body tissues and cerebrospinal fluid. Only about 25% of the dose given is absorbed. In neonates, young infants, and individuals with impaired kidney function, excretion is considerably delayed.

INDICATIONS: Phenoxymethyl penicillin is indicated in the treatment of mild to moderately severe infections caused by penicillin G-sensitive microorganisms that are sensitive to the low serum levels common to this particular dosage form. Therapy should be guided by bacteriological studies (including sensitivity tests) and by clinical response. Culture and sensitivity testing are especially important in suspected staphylococcal infections because increased resistance has been reported. Phenoxymethyl penicillin is not active against penicillinase-producing bacteria.

Note: Severe pneumonia, empyema, bacteremia, pericarditis, meningitis, and arthritis should not be treated with phenoxymethyl penicillin during the acute stage.

Indicated surgical procedures should be performed.

Medical conditions in which oral penicillin therapy is indicated as prophylaxis: For the prevention of recurrence following rheumatic fever and/or chorea. To prevent bacterial endocarditis in patients with congenital and/or rheumatic heart lesions who are to undergo dental procedures or minor upper respiratory tract surgery or instrumentation.

Note: Oral penicillin should not be used as adjunctive prophylaxis for genitourinary instrumentation or surgery, lower intestinal tract surgery, sigmoidoscopy and childbirth.

CONTRAINDICATION: A previous hypersensitivity reaction to any penicillin.

WARNINGS: Serious and occasionally fatal hypersensitivity (anaphylactoid) reactions have been reported in patients on penicillin therapy. While more frequent following parenteral therapy, anaphylaxis has occurred in patients on oral penicillins. These reactions are more apt to occur in individuals with a history of sensitivity to multiple allergens.

Some individuals with a history of penicillin hypersensitivity reactions have experienced severe hypersensitivity reactions from a cephalosporin. Before therapy with a penicillin, careful inquiry should be made concerning previous hypersensitivity reactions to penicillins, cephalosporins, and other allergens. If an allergic reaction occurs, the drug should be discontinued and the patient treated with the usual agents, e.g., pressor amines, antihistamines and corticosteroids.

PRECAUTIONS: Penicillin should be used with caution in individuals with histories of significant allergies and/or asthma.

The oral route of administration should not be relied on in patients with severe illness, or with nausea, vomiting, gastric dilatation, cardiospasm, or intestinal hypermotility.

Occasional patients will not absorb therapeutic amounts of orally administered penicillin.

In streptococcal infections, therapy must be sufficient to eliminate the organism (10 days minimum); otherwise the sequelae of streptococcal disease may occur. Cultures should be taken following completion of treatment to determine whether streptococci have been eradicated.

Prolonged use of antibiotics may promote the overgrowth of nonsusceptible organisms, including fungi. Should superinfection occur, appropriate measures should be taken.

ADVERSE REACTIONS: While the incidence of reactions to oral penicillins is much less than with parenteral therapy, it should be remembered that all degrees of hypersensitivity, including fatal anaphylaxis, have been reported with oral penicillin.

The most common reactions to oral penicillin are nausea, vomiting, epigastric distress, diarrhea, and black hairy tongue. The hypersensitivity reactions reported are skin eruptions (maculopapular to exfoliative dermatitis), urticaria and other serum sickness reactions, laryngeal edema, and anaphylaxis. Fever and eosinophilia may frequently be the only reaction observed. Hemolytic anemia, leucopenia, thrombocytopenia, neuropathy, and nephropathy are infrequent reactions and are usually associated with high doses of parenteral penicillin.

HOW SUPPLIED: Pfizerpen VK (potassium phenoxymethyl penicillin) for Oral Solution. Each 5 ml. of reconstituted solution contains potassium phenoxymethyl penicillin equivalent to 125 mg. (200,000 units) or 250 mg. (400,000 units) of phenoxymethyl penicillin.

125 mg. bottles of 100 ml. and 150 ml.

250 mg. bottles of 100 ml. and 150 ml.

Pfizerpen VK (potassium phenoxymethyl penicillin) Tablets. Each tablet contains potassium phenoxymethyl penicillin equivalent to 250 mg. (400,000 units) or 500 mg. (800,000 units) of phenoxymethyl penicillin.

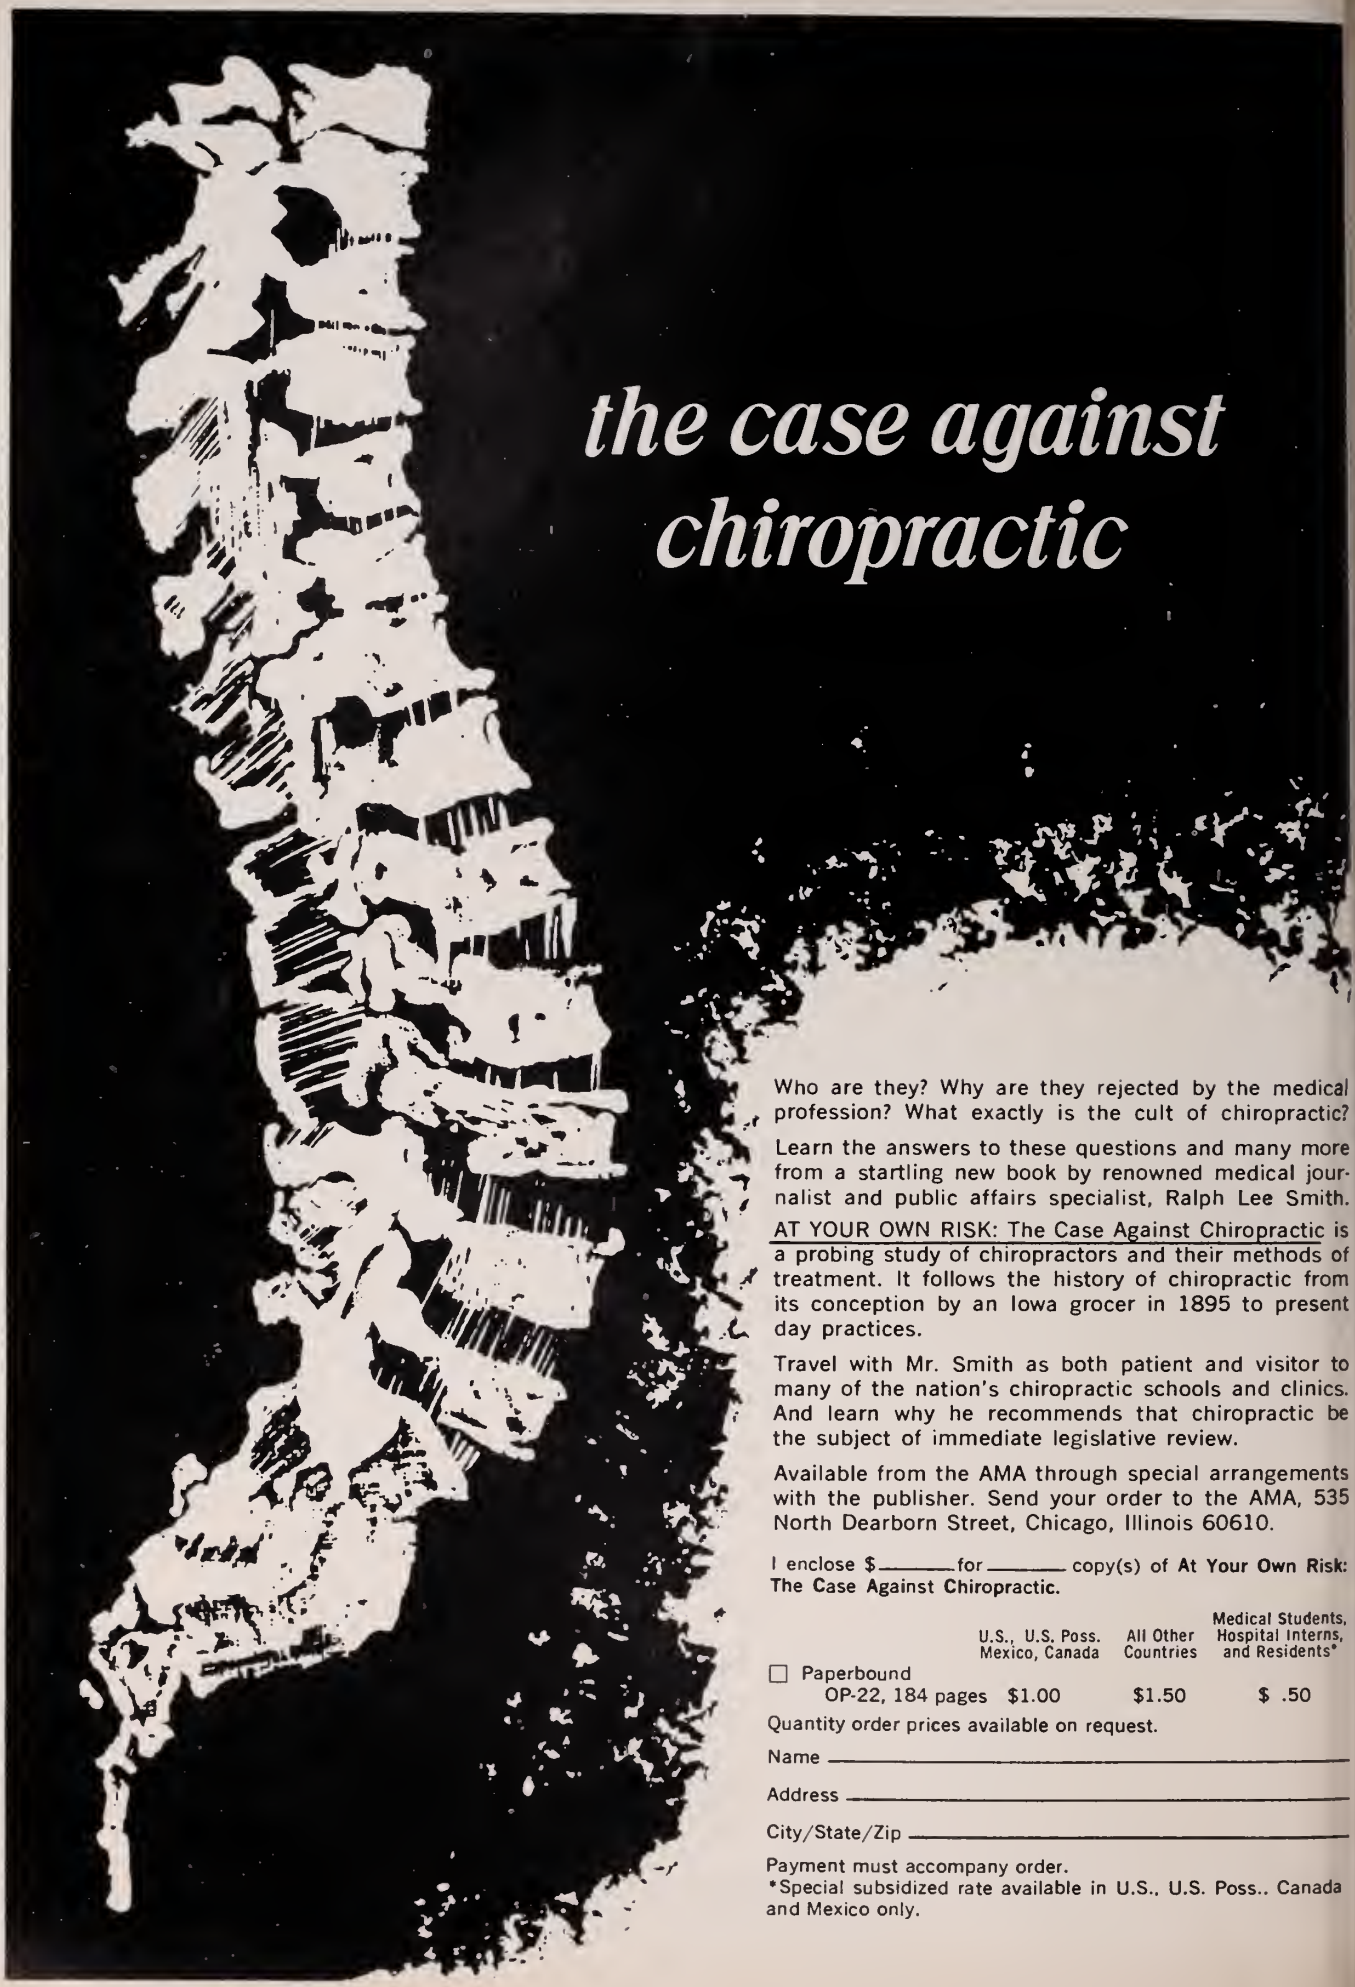
250 mg. bottles of 100.

500 mg. bottles of 100.

More detailed professional information available on request.

Pfizer LABORATORIES DIVISION
PFIZER INC. NEW YORK, N.Y. 10017

PFIZERPEN®
COMES THROUGH AGAIN.



Now there are *two* ways to cut the cost of brand-name penicillin therapy.

Pfizerpen VK now joins Pfizerpen G (potassium penicillin G) for *true* economy in brand-name penicillin therapy.

When you write penicillin VK, it's for acid stability, solubility and rapid absorption. But when you write **Pfizerpen VK,** you add economy. Pfizerpen VK, more economical than the two leading brand-name penicillin VK products. G or VK. Just make sure it's Pfizerpen.

Tablets and Powder for Syrup

PFIZERPEN® VK
(POTASSIUM PHENOXYMETHYL PENICILLIN)
G OR VK. JUST MAKE SURE IT'S PFIZERPEN.

the case against chiropractic

Who are they? Why are they rejected by the medical profession? What exactly is the cult of chiropractic?

Learn the answers to these questions and many more from a startling new book by renowned medical journalist and public affairs specialist, Ralph Lee Smith.

AT YOUR OWN RISK: The Case Against Chiropractic is a probing study of chiropractors and their methods of treatment. It follows the history of chiropractic from its conception by an Iowa grocer in 1895 to present day practices.

Travel with Mr. Smith as both patient and visitor to many of the nation's chiropractic schools and clinics. And learn why he recommends that chiropractic be the subject of immediate legislative review.

Available from the AMA through special arrangements with the publisher. Send your order to the AMA, 535 North Dearborn Street, Chicago, Illinois 60610.

Observing Externship for Sophomore Medical Students

LAUREL LEBENS;* LANCE PETERSON;* KEN SANSOME* AND JOHN VERBY, M.D.†

To SUPPLEMENT the basic science curriculum of the first two years of medical education with an introduction to clinical experience, students and staff at the University of Minnesota Medical School initiated an "observing externship" program for the class of 1972. Students (during their non-class hours) were placed with practicing physicians who volunteered their services in a mutual-learning experience. Students participated in the actual practice of medicine and learned basic clinical procedures; physicians were updated about medical education as it is. Both groups expressed satisfaction with the program and hope this experience will stimulate student consideration of a career in the practice of family medicine.

Traditionally medical education has been a two-year experience in the basic sciences based largely on didactic lectures and laboratory work followed by two-years' experience in clinical medicine. Since the 1972 class at the University of Minnesota was to be the last group to be so taught, some departments of the Medical School were willing to try new teaching approaches with this class.

In the spring of 1969, a discussion was held with the freshman class regarding the role of the general practitioner in dealing with psychiatric problems. An outline of newly planned programs for the incoming freshmen was also presented, which in turn interested members of the 1972 class.

As a result of this interest a program was arranged which permitted one or two students to meet with a practitioner every three or four weeks for a period of three to four hours. It was planned that one out of every four would be in a hospital visit with the remainder of the visits in the physician's office.

*Sophomore Medical Students, University of Minnesota Hospitals, Minneapolis, Minnesota.
†Associate Professor, Department of Family Practice and Community Health, University of Minnesota Hospitals, Minneapolis, Minnesota.

During the summer thirty physicians from the Twin Cities were contacted and volunteered for the program with the expectancy that thirty or forty students would like to participate. An orientation was held for the physicians, and the program goals were established: These were:

(1) To give students the opportunity to see the patient as a total person; (2) To allow the student to observe continuing comprehensive care of the patient and his family; (3) To give students the opportunity to see as much variety as possible from very simple to complex cases and (4) To allow the student to perform, under supervision, certain clinical skills such as knee aspirations, lumbar punctures, cut downs, IV starts, and normal deliveries. Physicians were asked to reduce patient load during student visits and to allow ample time for discussion of cases. The program was presented to students, for extracurricular involvement, in late September, and out of a class of approximately 150, 99 students desired to participate. By mid-November the program was under way with 99 students and 54 physicians.

Results

Student evaluation was sought at the completion of Fall and Winter quarters, the results of which appear in the following tables:

TABLE 1[1]

Comparison of Fall and Winter Questionnaire Responses from Sophomores Participating in the Observing Externship (N-99)

	Fall	Winter
% of students responding	83%	73%
% of students not meeting with assigned physician	5%	18%
Median number of sessions with physician	2	3
Median length of visit	2-5 hours	3-4 hours
Median number of patients per visit	5-10	6-10
Median number of hospital visits	1	1
Ratio of favorable:unfavorable comments on the program	11:1	8:1

TABLE 2[1]

*Sophomore Interest in Family Practice or General Practice After Two Quarters of the Observing Externship.**

Percent of Students Responding (N=60)

Very Interested	Mildly Interested	Undecided	Not Interested
60	28	12	0

*Taken from the Sophomore Observing Externship Questionnaire, Spring 1969.

Students began participating in physical diagnosis during the winter quarter as a scheduled part of the curriculum. This scheduled patient exposure may explain the small increase in lack of interest after winter quarter as shown in Table 1.

Stated criticisms of the program were: (1) Lack of student time; (2) Insufficient involvement in doing procedures; (3) Too many common, simple problems such as URI and (4) Lack of enthusiasm by some doctors.

Interest in family practice is shown in Table 2. Forty-five percent of those responding indicated the observing externship had affected their interest. Only three (5%) said they were less interested after participation.

Physician evaluation was sought at the end of spring quarter with a 63% return of questionnaires.

The overall response by physicians was favorable. They indicated a median number of 10 visits throughout the nine-month academic year to be an optimal arrangement. Of those responding, 80% felt the program was of benefit to the students.

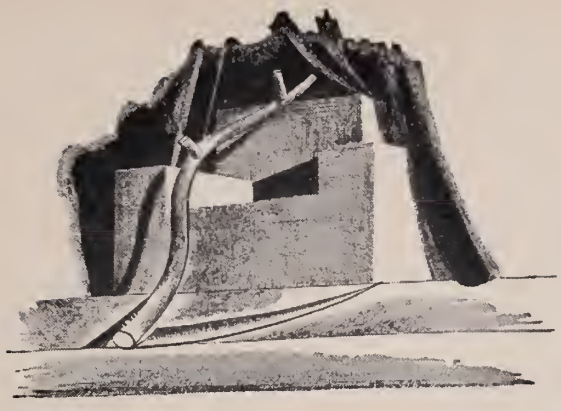
A random sample of students not participating in the program, gave as reasons for not doing so: "not enough time" for outside activities while in medical school; a lack of communication with the physician and declining interest on the part of the student due primarily to required participation in the Physical Diagnosis Course during the spring quarter.

TABLE 3[1]

Responses of Participating Physicians Regarding Some Aspects of the Sophomore Observing Externship (N=34)

	Percent of Physicians Responding
Desire to continue as preceptor	91%
Prefer 1:1 rather than 2:1 student-physician ratio	75%
Willing to have student do more as opposed to being primarily observers	
(a) in the office	60%
(b) in the hospital	50%
Willing to work with Freshmen	67%

Conclusion



From analysis of student evaluation data, the envisioned "Observing Externship Program" was a worthwhile experience for those students participating with a physician who was interested in teaching and achieving the goals of the program. The vast majority of physicians fulfilled the students' expectations. Since the basic criticism of the program was not enough extracurricular time available, this program should be made an integral part of the medical curriculum.

1. Cassie, Josephine M.: "A Look at the Undergraduate Programs of the Department of Family Practice and Community Health." A Report to the Educational Policy Committee, University of Minnesota, July 21, 1970.

Our Congratulations

Dr. Frank Hammond Krusen became the first honorary member of the Minnesota Physiatric Socicty on November 21, 1970. He had been nominated for this honor on September 15, 1970. An illuminated scroll, recognizing "his many contributions to the practice and advancement of physical medicine and rehabilitation," was presented in absentia at the time of the scientific meeting of the Society.

In Memoriam

A great man who neither sought nor shunned greatness, who found glory only because glory lay in the plain path of duty.—Macaulay

EDWARD J. ENGBERG, M.D.

Dr. Edward J. Engberg, 83, former superintendent of the Faribault State School and Hospital, died July 18. Born in Minneapolis, he was a graduate of the University of Minnesota Medical School. Dr. Engberg was a specialist in neuropsychiatry.

He was a member of the Phi Rho Sigma Medical Fraternity, a life member of the American Psychiatric Society, past president of the American Association on Mental Deficiency, a member of the Southern Minnesota Medical Society, diplomate of the Board of Psychiatry and Neurology, member of the Rice County Medical Society and American Medical Association, and a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Engberg is survived by his son and daughter.

ALVAN SACH-ROWITZ, M.D.

Dr. Alvan Sach-Rowitz, 77, Moose Lake physician and surgeon, died July 31. He was a graduate of St. Louis University Medical School and had practiced in Moose Lake since 1932.

He was a medical staff member of the Moose Lake Community Hospital and Mercy Hospital, a member of the St. Louis County Medical Society and the American Medical Association and a 50 Club Member of the Minnesota State Medical Association.

Dr. Sach-Rowitz is survived by his wife.

WILLIAM CARL KAUFMAN, M.D.

Dr. William C. Kaufman, 89, one of Minnesota's oldest practicing physicians, died May 8. On September 1st of last year, he would have completed 60 years of service to Appleton.

He had been mayor of Appleton several years, a member of the Board of Education for 11 years, president of the Kandiyohi-Swift-Meeker County Medical Society and the Camp Relief District Medical Society. Dr. Kaufman was a member of the American Medical Association, a surgeon for both the Milwaukee and Great Northern Railways and a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife, daughter, and a son, Dr. William C. Kaufman II of Green Bay, Wisconsin.

BERNARD SPENCER NAUTH, M.D.

Dr. Bernard S. Nauth, 60, general practitioner, died June 4. Born in Minneiska, Minnesota, Dr. Nauth attended the University of Minnesota Medical School. He had practiced in Winona, Minneapolis and Arizona.

He was a member of the Ramsey County Medical Society, American Medical Association and the Minnesota State Medical Association.

Dr. Nauth is survived by his wife and four children.

EMMETT V. KENEFICK, M.D.

Dr. Emmett V. Kenefick, 72, St. Paul physician, died June 24. Dr. Kenefick was born in Belmond, Iowa, and attended the University of Iowa Medical School.

Dr. Kenefick was vice president-elect of the Minnesota Academy of Medicine, a member of the Minnesota Society of Internal Medicine, Minnesota Academy of Medicine, Sigma Chi, Alpha Omega Alpha, Ramsey County Medical Society, American Medical Association and a Life Member of the Minnesota State Medical Asociation.

He is survived by his wife, daughter, and three sons.

RICHARD O. BURMEISTER, M.D.

Dr. Richard O. Burmeister, 52, St. Paul anesthesiologist, died July 21. Born in St. Paul, Dr. Burmeister attended the University of Minnesota Medical School.

He was former Chief of Staff at Midway Hospital and a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Burmeister is survived by his wife, six daughters and one son.

CLAUDE J. EHRENBERG, M.D.

Dr. Claude J. Ehrenberg, 77, of Boca Raton, Florida, retired Chief of Staff at Northwestern Hospital, died June 16. A Minneapolis native and former professor of obstetrics and gynecology at the University of Minnesota, Dr. Ehrenberg was a former medical director of the Hennepin County League for Planned Parenthood.

A former president of the Hennepin County Medical Society, he was also a member of the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

Dr. Ehrenberg is survived by his wife, three sons and a daughter.

HERMAN O. McPHEETERS, M.D.

Dr. H. O. McPheeters, retired Minneapolis surgeon and a pioneer in the treatment of varicose veins, died July 20. He was 80. A native of Mankato, he graduated from Northwestern University Medical School and practiced in Genoa, Illinois, and Redwood Falls, Minnesota, before going into practice in Minneapolis.

He was a member of the American Medical Association and the Hennepin County Medical Association, and a Life and 50 Club Member of the Minnesota State Medical Association.

Dr. McPheeters is survived by his wife, a daughter and a son.

RALPH D. HANOVER, M.D.

Dr. Ralph Hanover, 64, International Falls physician, died June 13. His medical education was obtained at the University of Minnesota Medical School.

He was a member of the Range Medical Society, the American Medical Association, Academy of General Practice, the Industrial Medical Association, and the Minnesota State Medical Association.

Dr. Hanover is survived by his wife, a son and a daughter.

THORVOLD J. JENSEN, M.D.

Dr. T. J. Jensen, 89, general practitioner and surgeon in Duluth for more than 60 years before his retirement, died March 8. Born in Bergen, Norway, Dr. Jensen came to the United States as an infant. He was graduated from Hamline University Medical School.

Dr. Jensen was a member of the St. Louis County Medical Society, American Medical Association and an honorary member of the St. Luke's and St. Mary's hospitals' staffs and a 50 Club and Life Member of the Minnesota State Medical Association.

He is survived by his two daughters and two sons.

PETER ARNOLD LOMMEN, M.D.

Dr. Peter A. Lommen, 77, longtime Austin physician, died March 16. A native of Vermillion, South Dakota, Dr. Lommen graduated from Rush Medical School in Chicago. He came to Austin in 1920 and had been a member of the St. Olaf Hospital staff since its organization.

Dr. Lommen was a member of the Mower County Medical Society and the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife and four sons, two of whom practice medicine in Austin.

CHARLES L. LICK, M.D.

Dr. Charles L. Lick, 78, St. Paul physician, died March 27. Born in St. Paul, he was a lifelong resident of the city and a physician and surgeon in St. Paul for more than 50 years.

He was a member of the Ramsey County Medical Society and the American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Lick loved to play golf and keep abreast with all the latest concepts of medicine and surgery. He was very proud of a case history of a young woman with a giant cell tumor and enjoyed telling this story.

Dr. Lick is survived by his widow and a son, Dr. Louis C. Lick of Edina.

KNUTE A. SPORRE, M.D.

Dr. Knute A. Sporre, 78, Fergus Falls physician, died March 17. In his early adolescence, Dr. Sporre had come to the United States from Sweden and later graduated from the University of Iowa College of Medicine in 1919. In his early practice, he had served southwestern Minnesota and northwestern Iowa.

Dr. Sporre was a member of the Park Region District and County Medical Society, the American Medical Association and was a 50 Club and member of the Minnesota State Medical Association.

GEORGE E. NELSON, M.D.

Dr. George E. Nelson, 46, Minneapolis orthopaedics surgeon, died September 28. Born in Detroit, Michigan, Dr. Nelson later attended the University of Minnesota Medical School.

He was a member of the Hennepin County Medical Society, the American Medical Association and the Minnesota State Medical Association.

Dr. Nelson is survived by his wife, a son, and two daughters.

KENNETH W. WILDER, M.D.

Dr. Kenneth W. Wilder, 87, Minneapolis physician, died October 8. He had practiced medicine in Minneapolis over fifty years and was Assistant Chief of Staff of St. Barnabas Hospital.

Born in Morristown, Minnesota, Dr. Wilder attended the University of Minnesota Medical School. He was a member of the Hennepin County Medical Society and the American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

HARRY LEROY BERGE, M.D.

Dr. Harry Berge, 53, Mora physician died September 9th of a heart attack while on a hunting trip. He had received his medical education from the University of Minnesota.

A member of the East Central County Medical Society and the American Medical Association, Dr. Berge was also a member of the Minnesota State Medical Association.

He is survived by his wife and two children.

JAMES H. MATTHEWS, M.D.

Dr. James Matthews, 46, professor of anesthesiology at the University of Minnesota and one of the leading nominees for the position of dean of the Medical School, died October 7, in Hartford, Connecticut, of an apparent heart attack. He was attending a meeting of the American Board of Anesthesiology and was president-elect of the organization.

He was a member of the Ramsey County Medical Society, the American Medical Association and the Minnesota State Medical Association.

Dr. Matthews is survived by his wife, a daughter and two sons.

The girth control pill

Tepanil® Ten-tab®

(continuous release form)

(diethylpropion hydrochloride, N.F.)

When girth gets out of control, TEPANIL can provide sound support for the weight control program you recommend. TEPANIL reduces the appetite—patients enjoy food but eat less. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation.

Contraindications: Concurrently with MAO inhibitors, in patients hypersensitive to this drug; in emotionally unstable patients susceptible to drug abuse.

Warning: Although generally safer than the amphetamines, use with great caution in patients with severe hypertension or severe cardiovascular disease. Do not use during first trimester of pregnancy unless potential benefits outweigh potential risks.

Adverse Reactions: Rarely severe enough to require discontinuation of therapy, unpleasant symptoms with diethylpropion hydrochloride have been reported to occur in relatively low incidence. As is characteristic of sympathomimetic agents, it may occasionally cause CNS effects such as insomnia, nervousness, dizziness, anxiety, and jitteriness. In contrast, CNS depression has been reported. In a few epileptics an increase in convulsive episodes has been reported. Sympathomimetic cardiovascular effects reported include ones such as tachycardia, precordial pain, arrhythmia, palpitation, and increased blood pressure. One published report described T-wave changes in the ECG of a healthy young male after ingestion of diethylpropion hydrochloride; this was an isolated experience, which has not been reported by others. Allergic phenomena reported include such conditions as rash, urticaria, ecchymosis, and erythema. Gastrointestinal effects such as diarrhea, constipation, nausea, vomiting, and abdominal discomfort have been reported. Specific reports on the hematopoietic system include two each of bone marrow depression, agranulocytosis, and leukopenia. A variety of miscellaneous adverse reactions have been reported by physicians. These include complaints such as dry mouth, headache, dyspnea, menstrual upset, hair loss, muscle pain, decreased libido, dysuria, and polyuria.

Convenience of two dosage forms: TEPANIL Ten-tab tablets: One 75 mg. tablet daily, swallowed whole, in mid-morning (10 a.m.). TEPANIL: One 25 mg. tablet three times daily, one hour before meals. If desired, an additional tablet may be given in mid-evening to overcome night hunger. Use in children under 12 years of age is not recommended.

Painful night leg cramps...

unwelcome bedfellow for any patient– including those with arthritis, diabetes or PVD

- Prevents painful night leg cramps
- Permits restful sleep
- Provides simple convenient dosage— usually just one tablet at bedtime

Prescribing Information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** Quinamm is contraindicated in pregnancy because of its quinine content. **Precautions/Adverse Reactions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

Specific therapy for night leg cramps.

Clinical Path Conference

Abdominal Pain, Confusion, and Intermittent Fever in an Elderly Male

CALVIN L. STRAND, M.D.* and ROBERT A. VAN TASSEL, M.D.†

First Admission

A 73-year-old man, rather darkly pigmented and cachectic was admitted to the hospital because of abdominal pain. He was confused, disoriented and unable to give much history. He said that he had not eaten for five days and was too weak to walk.

Physical Examination

His blood pressure was 140/70; pulse 70 and regular; respirations 16; and temperature 99°. His mucous membranes were dry and his skin turgor poor. The lungs were clear. His heart was not enlarged. A moderately loud systolic murmur was heard at the left sternal border and transmitted into the right side of the neck. The abdomen was distended and physical signs of ascites were present. There was no abdominal tenderness, no palpable organs or masses. The remainder of the physical examination was normal.

Laboratory

Hemoglobin was 13.1 gm % on admission but fell to 10.7 gm % after overnight hydration. White blood count was 6,800 with 77% neutrophils, 24% lymphocytes and 1% monocytes. The urine had a specific gravity of 1.017, gave a 1+ test for albumin, but contained no sugar and no formed elements. Serum sodium was 146 mEq/L; potassium 3.4 mEq/L; chloride 97 mEq/L; CO_2 25 mEq/L. Total serum proteins were 6.7 gm % with 2.0 gm % albumin. Alkaline phosphatase was 15 KA units; bilirubin 1.9 mg % and blood urea nitrogen 15 mg %. Blood glucose was 129 mg %. A cephalin flocculation test was 4+ and thymol turbidity 18.5 units. The serum transaminase was 60 units. The prothrombin time was 13.6 seconds with a control of 12.6 seconds. An electrocardiogram revealed non-specific ST-T changes.

A chest roentgenogram was normal except for elevated diaphragms. Abdominal films showed evidence of ascites. An excretory urogram revealed small kidneys with slight loss of the renal cortices. The collecting systems appeared normal. A brain scan and an upper gastrointestinal series were normal. A liver scan reportedly showed a small liver.

Cultures of the sputum, urine, and stool produced no pathogenic organisms; smears of sputum for acid-fast bacilli were negative. Red cell indices were as follows: MCV: 89; MCH: 27; MCHC: 31.

Hospital Course

Throughout his hospital course the patient remained somewhat confused and withdrawn. On several days his temperature rose to between 101° and 102° but then returned to normal without specific therapy. On the second hospital day a diagnostic paracentesis was performed with removal of 500 cc of reddish-brown fluid containing 220 white blood cells 77% of which were mononuclear cells, 14% neutrophils and 9% tissue cells. The ascitic sugar content was 125 mg %; the protein 2.4 gm %, and the specific gravity 1.016. The fluid contained 16,250 red blood cells per cubic millimeter. Smears for acid-fast bacilli were negative. Cytological examination demonstrated "abundant red cells, numerous small mononuclear cells, lymphocytes and histiocytes." There were no malignant cells.

The serum iron determination was 40 mcg % with an iron-binding capacity of 139 mcg % and the resulting saturation of 29%. Serum vitamin B-12 was 1,625 picogram‡/ml. (normal 150 to 600 picograms/ml.) and folic acid 2.4 millimicrograms/ml. (normal 5.3 to 17). The patient was given a multiple vitamin preparation and supplemental thiamine as well as ferrous gluconate and folic acid. On the 25th hospital day he was discharged to a nursing home.

*Formerly Resident, Department of Pathology, Hennepin County General Hospital, Minneapolis, Minnesota. Presently, Chief of Laboratory Service, Memphis Naval Hospital, Millington, Tennessee.
†Former Resident, Department of Internal Medicine, Hennepin County General Hospital Minneapolis, Minnesota. Now practicing in Minneapolis.
‡One picogram = 10^{-12} grams.

Second Hospitalization

Approximately two weeks after discharge the patient developed a temperature of 103°, became unresponsive, and was re-admitted to the hospital. Examination: The patient was stuporous with only slight response to painful stimulation. The blood pressure was 60/40; pulse 120; temperature 102.2°. His skin was warm and dry with peripheral cyanosis. The conjunctiva of the right eye was reddened and the orbit was red and edematous; the pupils were of equal size and reacted normally to light. A purulent discharge was present in the right ear canal. The neck was rigid. The lungs were clear. The heart was of normal size. Occasional premature beats were audible but no murmur was heard. The abdomen was flat and sunken and no masses or organs were felt. There was a hematoma present over the right elbow and a superficial skin laceration near the right wrist. Deep tendon reflexes were hypoactive but symmetrical.

The hemoglobin was 10.5 gm %; the white blood count 8,400 with 88% neutrophils and 12% lymphocytes. Toxic granulations were described in the neutrophils. The urine was yellow with a specific gravity of 1.015 and gave a 2+ test for albumin and a negative test for sugar. Microscopic examination of the urine revealed packed fields of white blood cells. The cerebrospinal fluid was clear, contained no cells and had a protein content of 125 mg % and a sugar of 20 mg %. The blood glucose was 55 mg %. Serum sodium was 151 mEq/L; potassium 2.6 mEq/L; chloride 106 mEq/L; and CO_2 21 mEq/L. The blood urea nitrogen was 36 mg %. Specimens of cerebrospinal fluid, blood, urine and the discharge from the right ear were submitted for culture and treatment was begun with kanamycin and cephalothin.

Despite these antibiotics and the administration of intravenous fluids, the patient's blood pressure continued to fall and he expired four and one-half hours after admission.

Dr. Robert Van Tassel:

The case is that of a 73-year-old cachectic male with ascites. The history is of little help in arriving at a diagnosis and the laboratory is not particularly revealing. The differential diagnosis is that of a cachectic male with ascites, and would include cirrhosis, neoplasm with peritoneal implants, tuberculosis, hepatoma, congestive heart failure, pancreatitis and peritonitis. Let us now consider each of these major diagnostic possibilities with respect to this case.

Cirrhosis

The ascitic fluid in cirrhosis is classically a transudate: it has a low specific gravity, a low protein, and usually is clear yellow. The specific gravity is usually less than 1.008 and very rarely exceeds 1.015. The protein content is generally between 1 to 2 gm %, and only rarely exceeds 3 gm %. The ascitic fluid in this patient is bloody, with many mononuclear cells, and an elevated protein; it is not the classic ascitic fluid seen in cirrhosis. However, one may occasionally see serosanguineous ascitic fluid in cirrhotic patients. When present it is thought to be a result of a breakdown of adhesions about the liver as it contracts in size. Thus the ascitic fluid could be secondary to cirrhosis, although the content of the ascitic fluid produced in this case was not entirely typical.

Neoplasms with Peritoneal Implants

A serosanguineous fluid, high in protein content, is characteristic of the ascitic fluid associated with carcinomatosis. An experienced cytologist will find malignant cells in the ascitic fluid in 50 to 60% of the cases. No mention is made of positive cytology on the examination of the ascitic fluid in this case. The primary site for carcinoma with metastasis to the peritoneum would be stomach, pancreas, colon or rectum. In the female, the ovary would be added to this list. Primary carcinoma of the peritoneum is a very rare disease and is not usually associated with ascites. Rapid emaciation and cachexia are the rule. The serosanguineous ascitic fluid strongly suggests malignancy.

Tuberculosis

Tuberculous peritonitis or miliary tuberculosis with ascitic fluid production is found most commonly in children. Patients with ascites secondary to tuberculosis almost without exception have some manifestation of tuberculosis elsewhere in the body. The fluid may be serosanguineous and has many mononuclear cells. The characteristic features are abdominal pain, fever, and evidence of tuberculosis elsewhere. The liver function studies are usually normal. Occasionally one can feel the thickened nodules in the peritoneum on examination of the abdomen. In this case, the ascitic fluid is certainly consistent with a diagnosis of tuberculosis. However, the absence of evidence of tuberculosis on the chest x-ray or elsewhere in the body, and the fact that the acid-fast stain of the peritoneal fluid was negative would tend to make this diagnosis less likely.

Hepatoma

Ascites is present with hepatoma in approximately 60 to 70% of the patients. The fluid is characteristically serosanguineous. The liver is hard and enlarged in three of four cases. The classic laboratory finding is a high alkaline phosphatese with a moderately elevated serum bilirubin. Hepatoma is more common in men and most common in the fifth and sixth decades. It is associated with cirrhosis and is 20 times more frequent among cirrhotics than among the general population. The findings of the laboratory analysis of the ascitic fluid in this case would be consistent with, although not diagnostic of, a hepatoma. The fact that the patient's liver was not palpable and that the liver scan showed a small liver would make the diagnosis of hepatoma unlikely.

Congestive Heart Failure

Classically, patients with congestive heart failure may have ascites; however, the absence of other manifestations of congestive heart failure and the normal chest x-ray make a diagnosis of congestive heart failure quite unlikely. Constrictive pericarditis would have to be considered, but the other characteristic findings of constrictive pericarditis are not given in the protocol; therefore this would be an unlikely diagnosis.

Hemorrhagic Pancreatitis

Hemorrhagic pancreatitis commonly produces ascites. The ascitic fluid is serosanguineous and would be compatible with fluid obtained in this case. Nevertheless, the history is not consistent with that of hemorrhagic pancreatitis and the physical examination of the initial admission showed no evidence of abdominal pain or tenderness. No mention is made of an elevated amylase in the serum, urine or ascitic fluid. The diagnosis of hemorrhagic pancreatitis, I believe, can be excluded.

Peritonitis

Peritoneal irritation secondary to bacterial invasion usually produces an acute abdomen with prominent findings. Serosanguineous ascitic fluid can be produced but it is not common. The finding of many mononuclear cells in the ascitic fluid and the physical examination in this case helps rule out this diagnosis.

Additional Data

Normochromic Anemia

A normochromic, normocytic anemia which is non-diagnostic but is compatible with most of the entities was being considered.

Vitamin B-12

The serum B-12 level is 1,640 picograms/ml, which is markedly elevated. The B-12 levels are markedly elevated in acute myeloblastic leukemia, chronic myelocytic leukemia, and chronic liver disease. However, it is possible this patient had a serum level drawn shortly after the administration of intramuscular B-12; so it is doubtful that the elevated B-12 would be of help in arriving at the diagnosis in this case.

Folic Acid

The serum folic acid is 2.4 millimicrograms/ml, which is slightly below normal and consistent with a 74-year-old cachectic male with liver disease. This probably represents dietary deficiency.

Serum Iron

Serum iron is 40 mcg % and iron-binding capacity is 130 with 29% saturation; both are consistent with chronic infection. Anemia is found in 75% of cases of chronic liver disease and is usually associated with blood loss, increased hemolysis or decreased erythropoiesis as well as with vitamin deficiency.

Liver Function Tests

The liver function studies are compatible with those of a long-standing cirrhotic. The bilirubin is mildly elevated to 1.9 mg % and the alkaline phosphatese is 15 KA units; the cephalin floc is 4+; the thymol turbidity, 18.5; the SGOT, 60 units; and the prothrombin time is 13.6 with a control of 12.6. The 4+ cephalin flocculation and the thymol turbidity of 18.5 would both indicate fairly long-standing liver disease. All the liver function abnormalities could be explained on the basis of cirrhosis.

Progress

The patient's hospital course showed him to be intermittently confused and febrile, but confusion in the elderly hospitalized male is not at all uncommon. Nevertheless, one would have to consider hypoxia, chronic subdural hematoma, drug intoxication, cerebrovascular disease, or neurosyphilis. Intermittent fever is consistent with chronic liver disease, occult malignancy, and bacterial infections such as tuberculosis and fungal disease. Specimens of blood, urine, and sputum from this patient apparently were cultured for pathogenic organisms and none were found. Therefore, organisms that are not as readily cultured such as Mycobacterium tuberculosis must be strongly considered.

The patient was discharged from the hospital to a nursing home and was re-admitted in septic shock two weeks later. His blood pressure was 60/40, his temperature was 104°; and he was unresponsive. At this time the physical findings of a "red orbit and red conjunctiva" along with a draining right ear make the diagnosis of cavernous sinus thrombosis very tempting. However,

no supporting evidence for cavernous sinus thrombosis is present, such as pupillary changes which may or may not be present, involvement of cranial nerves II, III, IV, and VI which travel through the cavernous foramen, edema of the eyelid or cornea, or papilledema. The cerebrospinal fluid is clear and has a normal pressure which makes the diagnosis of cavernous sinus thrombosis untenable. The cerebrospinal fluid protein was elevated to 125 mg % and the sugar reduced to 20 mg %. The low cerebrospinal fluid sugar is probably a reflection of a low blood glucose level of only 55 mg %. The elevated spinal fluid protein, however, must be explained. Isolated cerebrospinal fluid protein elevation with a normal cell count is seen in myxedema, collagen disease, diabetes mellitus, and tumor. In this case there is no evidence of myxedema, collagen disease, or diabetes; however, the possibility of malignancy is a consideration. For instance, carcinoma of the pancreas with metastasis to the peritoneum and brain could result in the production of serosanguineous ascitic fluid and mental confusion, as seen in this case. But the absence of other findings suggestive of a tumor, including a negative ascitic fluid, discount this diagnosis. The final diagnosis would most likely be alcoholic liver disease as manifested by cirrhosis and supported by the small liver. The patient's demise was probably due to gram-negative septicemia which may have been from his urinary tract; also aspiration pneumonia cannot be entirely ruled out.

Pathology Discussion

Dr. Calvin Strand:

One factor which made this a difficult clinical diagnostic case was that this patient was suffering from multiple diseases.

Autopsy findings: The body was that of an elderly, cachectic white male. There were approximately three to four liters of brown fluid in the peritoneal cavity. The peritoneal surfaces displayed numerous adhesions but no evidence of tumor. The heart was of normal weight (300 gm), but the right coronary artery showed marked atherosclerotic narrowing at its take-off with only a pin-point lumen remaining. Also the left coronary artery revealed significant narrowing, particularly in its terminal branches. Microscopic examination of the myocardium showed diffuse patchy fibrosis but no evidence of acute infarction. The lungs were relatively heavy with a combined weight of 1950 gm. At the time of the gross autopsy it was stated that the lungs appeared somewhat consolidated and pneumonia was suspected. However, when the histologic sections were examined later, an interesting and extremely important finding was present. The pulmonary parenchyma was studded with numerous granulomas, most of which showed central caseation (Figure 1). A Ziehl-Neelsen stain revealed the presence of slender straight acid-fast bacilli. The fact that the granulomas were quite small and studded throughout all of the lung blocks taken at autopsy suggested a miliary pattern of distribution. The liver was rather small, weighting 1,000 gm. The external surface was reddish-yellow in color and somewhat nodular, suggesting cirrhosis. The histologic sections showed general loss of the normal lobular architecture and the presence of numerous large connective tissue bands connecting adjacent portal areas. The latter features are consistent with Laennec's cirrhosis. Also, numerous granulomas were scattered throughout the hepatic parenchyma (Figure 2), some of which again showed central caseation. The liver also displayed the findings of alcoholic hepatitis (Figure 3). as represented by the presence of numerous cytoplasmic, eosinophilic masses

having the appearance of alcoholic hyaline, fatty metamorphosis, focal areas of hepatocellular degeneration, and a polymorphonuclear leucocytic infiltrate. The spleen showed involvement with numerous granulomas. One of the adrenal glands also contained a small granuloma made up of epithelioid cells and inflammatory cells. Histologic examination of the peritoneal surfaces showed no evidence of tuberculosis. The brain and kidneys revealed no evidence of involvement, either. Unfortunately, the bone marrow was not examined.

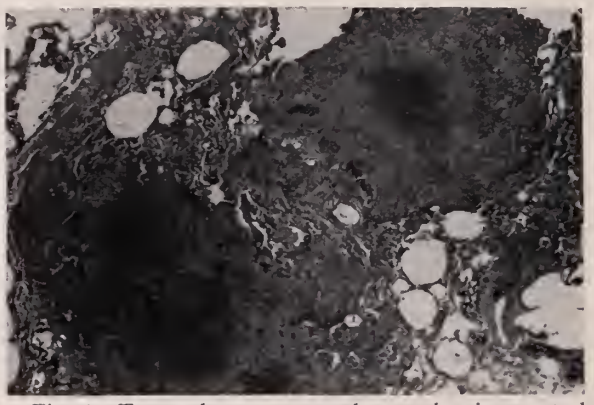

Fig. 1—Two pulmonary granulomas showing central caseation necrosis.

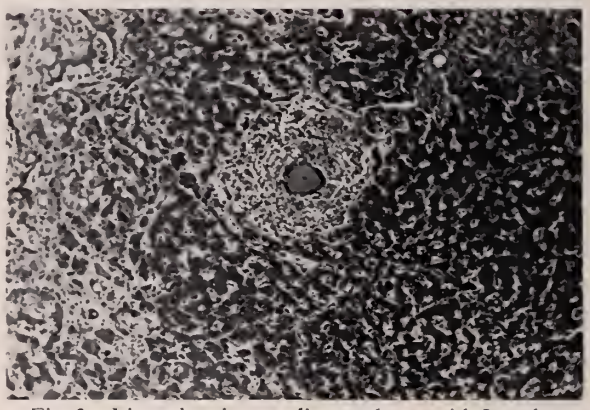

Fig. 2—Liver showing small granuloma with Langhans-type giant cell in center.

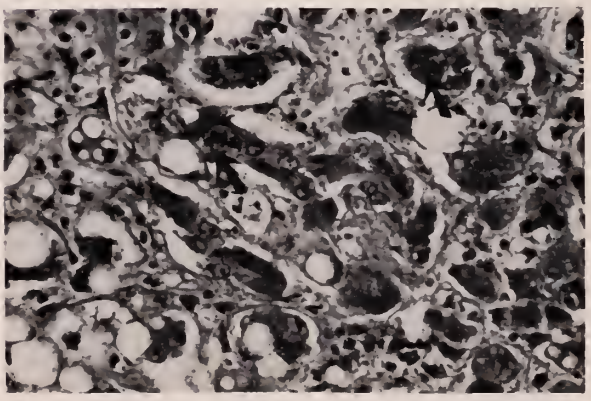

Fig. 3—Liver showing features of alcoholic hepatitis including alcoholic hyaline (arrows).

Pathologic Diagnoses

1. Miliary tuberculosis involving the lungs, liver, spleen, and adrenals.
2. Laennec's cirrhosis and acute alcoholic hepatitis.
3. Marked coronary artery atherosclerosis with diffuse myocardial fibrosis.

Miliary tuberculosis refers to that form of tuberculosis produced by dissemination of the tubercle bacilli throughout the body through the blood stream and characterized by the development of innumerable small tubercles in certain organs which are most susceptible to the infection. Tubercle bacilli may get into the blood stream either by the lymph vessels and lymph nodes, or by the rupture of a caseous focus into a blood vessel. Certain organs such as the lungs, liver, spleen, adrenals, kidneys and meninges seem to be most susceptible to miliary infection. This disease is most apt to occur at the extremes of life, and adrenal steroid therapy and pregnancy increase susceptibility.

The clinical picture is quite variable. The patient may be acutely ill with night sweats, chills, fever, cough and weight loss; and the disease may progress rapidly, causing death before a diagnosis can be established. At other times, the disease may be insidious with little fever and only weakness and weight loss. The physical examination is usually non-contributory except that one may observe tubercles in the optic fundi on funduscopic examination. A chest film may be helpful in showing numerous tubercles. However, it must be remembered that a complete clinical picture may precede development of the x-ray picture. The tuberculin test may be negative (anergic) in an acutely ill patient. It is extremely important to make the diagnosis, however, as untreated miliary tuberculosis is invariably fatal and is frequently complicated by the development of tuberculous meningitis. It is worthwhile to remember that miliary tuberculosis often involves the retina, bone marrow, and liver, and that these sites offer valuable clinical opportunities to make the diagnosis. The tubercles can be visualized in many instances in the eyegrounds by simple funduscopic examination; and bone marrow aspiration and liver biopsy provide the opportunity for identifying, by both cultural and histologic techniques, the miliary dissemination of the organism.

Cases of undiagnosed fatal tuberculosis, such as the one discussed today, are not as uncommon as one might suspect. Casey,[1] reporting on 2,000 autopsies done in a five-year period, states that tuberculosis was the main cause of death in 28 or 1.4% of the cases. Interestingly enough, tuberculosis was undiagnosed in 14 of these cases (0.7%) and was not recognized at the gross postmortem in seven cases (0.35%). Thus, this is a disease that may be missed not only clinically but also at gross autopsy and not recognized until the time of microscopic examination of the autopsy tissue sections.

Legislative

MINNPAC/AMPAC:
What's It All About??

R. L. ENGWALL, M.D.*

TEN YEARS AGO the AMA is frank to say, the medical profession had difficulty getting members of Congress to listen to its views. This is not the case today according to AMA's representatives in Washington. This noticeable change, most observers feel, can be credited to the medical PAC movement. Money raised and distributed by AMPAC (American Medical Association Political Action Committee), the AMA's political arm and its state counterparts, such as MINNPAC (Minnesota Medical Political Action Committee), has in fact created a considerably better climate in which medicine's views are heard on the multitude of health related legislation continually facing the Congress.

This improved legislative climate is a direct result of increasing and focusing physician involvement in the election process through a single organization. Greater impact is thus provided in helping to elect responsible men and women in both parties to Congress and to our own Minnesota State Legislature.

AMPAC was formed in 1961 to provide AMA members with a legal vehicle for direct contribution to political candidates. MINNPAC (formerly NUHOPE) was established in 1962 as the State counterpart to AMPAC.

The Federal Corrupt Practices Act forbids political contributions by tax exempt organizations such as the AMA and Minnesota State Medical Association. Like the COPE, the AFL-CIO's Committee on Political Action, AMPAC/MINNPAC solicits individual contributions to support political candidiates. In Minnesota each $25.00 contributed provides the physician, physician's wife or other contributor with a $15.00 MINNPAC membership and a $10.00 AMPAC membership. Also available and encouraged are sustaining memberships of $100.00 which are divided equally between AMPAC and MINNPAC.

MINNPAC and AMPAC have two basic objectives. The first is to provide political education for physicians and their wives to encourage them to participate actively in politics. The second is to provide direct assistance to candidiates for political office by mobilizing volunteers and financial contributions.

MINPAC dues dollars are used primarily to help elect State legislators in both parties who will maintain a responsible, open minded attitude towards health related legislation.

AMPAC dues dollars are used similarly in Congressional races throughout the country including Minnesota. For every dollar that AMPAC contributes, however, it is estimated that four or five times that much is raised additionally by state and local candidate support committees which have been organized.

AMPAC and its state and local counterparts (MINNPAC) rank very high among political organizations in terms of the money they disburse to political candidates—perhaps second only to COPE. An unidentified member of Congress has been quoted as saying, "If it hadn't been for AMPAC, a good many members of Congress would not be here today." The impact of this medical political action has strengthened medicine's voice in the Congress and in the state legislature.

AMPAC and MINNPAC do not lobby; this is a function of the AMA and the Minnesota State Medical Association. PAC activities, however, have been a great assistance to the legislative efforts of both the AMA and Minnesota State Medical Association. Former AMA President, Walter C. Bornemier, expressed it this way: "Before AMPAC was formed 10 years ago, we couldn't even get an audience with Congressmen or legislators. Now, we are heard and respected. AMPAC has helped us buy the right to a dialogue."

Dr. John L. Falls, Chairman of the Minnesota State Medical Association Committee on Public Policy states that there is no question but that Minnesota State Medical Association representatives are given a better hearing by State legislators who have had physician support through MINNPAC in their own districts at campaign time. He feels emphatically that MINNPAC has been of great assistance to the Minnesota State Medical Association in accomplishing its legislative goals and objectives.

AMPAC and MINNPAC are both non-profit,

*Chairman, Minnesota Medical Political Action Committee.

unincorporated bodies. AMPAC's activities are supervised by a bi-partisan ten-man Board of Directors appointed annually by the AMA's Board of Trustees. MINNPAC has a Board of Directors consisting of nine Councilor District representatives appointed by the Minnesota State Medical Association Council plus two directors from each of Minnesota's eight Congressional Districts and from three to five more additional at large directors selected by the 9 Councilor District representatives.

A candidiate review committee appointed by these directors makes recommendations to the MINNPAC Board of candidates who they feel merit financial support based on the candidates voting record and/or his receptivity to medically related issues. The opinions of physicians in the candidate's district is also solicited in making these evaluations on candidate support.

In 1970 MINNPAC contributed financially to 108 State Senate and House candidates out of a possible 202 contests. Eighty-eight percent of the DFL candidates and 65% of the conservative candidates, were winners.

Nationally AMPAC was successful in over 75% of the Congressional campaigns it participated in.

While the track record of AMPAC and MINNPAC is good, it can and must be improved on. Many physicians have yet to write their first $25.00 check to MINNPAC. The impact of MINNPAC and AMPAC would be increased considerably were all Minnesota physicians to become members in 1972.

Each year the volume of health related legislation grows in number and complexity at both the state and national levels. It is, therefore, imperative that medicine becomes more actively involved in the election of candidates who are knowledgeable and responsible in their attitude toward improving the delivery of health care. Active personal involvement in campaigns is most desirable, however, MINNPAC membership dues provide the physician and his wife an opportunity to help strengthen medicine's voice with but a small financial expenditure.

The 1972 elections will be crucial for medicine. Every physician who is concerned with the type of national health insurance which will presumably be enacted in 1973 should be vitally interested in helping to elect the right men and women to Congress in 1972, not only in Minnesota but all over the nation. New MINNPAC memberships are essential to fulfill this objective.

At the AMA meeting this summer, the President of the United States addressed the House of Delegates and challenged them with this statement: "America needs leadership from you in the medical profession, and your wives. I know many of you are so concerned whenever anybody suggests that you get into politics, and I do not speak in any partisan sense. I am not concerned whether you are in one party or the other. The main thing is to be in. I have heard a doctor say on occasion, 'I am only interested in my profession; I am not interested in politics.' Let me tell you something, he better get interested in politics or he won't have any profession to be interested in." In that statement, President Nixon said it all.

Was there no milder way but the smallpox,
The very filth'ness of Pandora's box?
So many spots, like *noeves*, our Venus soil?
One jewel set off with so many a foil!
Blisters with pride swell'd, which thro' 's flesh did sprout,
Like rose-buds, stuck i' th' lily skin about.
Each little pimple had a tear in it,
To wail the fault its rising did commit:
Who, rebel-like, with their own lord at strife.
Thus made an insurrection 'gainst his life.
Or were these gems sent to adorn his skin,
The cab'net of a richer soul within?
No comet need foretell his change drew on,
Whose corpse might seem a *constellation*.*

*John Dryden: Upon the Death of the Lord Hastings. Lines 53-66, 1649.

Book Reviews

HEREDITY, DISEASE & MAN: GENETICS IN MEDICINE by Alan E. H. Emery, M.D.; University of California Press, Berkeley and Los Angeles; 1968; Price: $6.85.

This book is the second volume in the series "Perspectives in Medicine" published by the University of California Press. The advances in genetics are coming so rapidly that the gap between the technical information reported in conferences and published in journals and that which is available to the general physicians or interested non-medical personnel has become increasingly wide.

This short and readable book presents the current fundamentals of genetics in terminology which is understandable by high school or college graduates working in fields related to medicine or who merely have the curiosity to know more about genetics. Because it provides an excellent overview of the field, it would be suitable reading in preparation for a course in human genetics, although it is not comprehensive enough to serve as a textbook for such a course. It may be of particular interest to the physician who frequently has responsibility counseling parents, because it will give him a quick and complete overview of the subject in language which he can in turn use directly in dealing with the parents. It will also give him the additional advantage of being significantly ahead of the genetics courses that the parents may be studying in random issues of current popular magazines. If this book can be considered a harbinger of other books in this series, "Perspectives in Medicine," physicians should keep their eyes on that series for providing a gentle introduction to the intrigue of medicine to members of their families and to other young people in the community who might venture into one of the medical or paramedical fields. The physician can safely recommend "Heredity, Disease & Man" to any high school or college student who expresses an interest in the medical areas; for the book will intrigue, delight, and inform him without frightening him with technicalities, abstruse and difficult language and formulas.

Warren J. Warwick, M.D.
Minneapolis, Minnesota

INTRODUCTION TO PROTOZOOLOGY by Menwell; Dover Publications, Inc., New York; Price: $4.00.

This is a very complete, comprehensive monograph on the study of protozoa. It comprises 28 chapters, the first 12 of which are related to the basic studies: ecology, morphology, nutrition, metabolism, etc. The remaining chapters deal principally with the classification and identification of the numerous species. The chapter on ecology is pertinent at the moment because of the current interest in the numerous types of contamination: "Natural purification depends primarily on the activities of a variety of microorganisms plus such agencies as oxidation reduction and sunlight. The protozoa make a dual contribution. Some, such as bacteria feeders, tend to reduce the bacterial contact; others promote oxidation by the liberation of oxygen as a byproduct of chlorophyll synthesis. The most active consumers of bacteria are probably the vorticellids.

Carl O. Rice, M.D.
Minneapolis, Minnesota

COMMUNITY RESPONSE TO ALCOHOLISM AND HIGHWAY CRASHES, 1970, Highway Safety Research Institute, The University of Michigan, $6.50.

and

THE ALCOHOL-IMPAIRED DRIVER AND HIGHWAY CRASHES, OCTOBER 1970, Minnesota Department of Public Safety, St. Paul, Minnesota.

There is a rising tide of awareness of the terrible contribution that alcoholism makes to highway injuries. A very thorough review of possible community action was carried out in a national symposium at Ann Arbor in 1969. The proceedings of this conference make hard reading but provide a very complete report of the stage of thinking in our country at this time. It is an excellent compilation for anyone who wishes to engage himself in a serious effort to improve this problem in public health.

The second pamphlet is a sleeper, a little gem of current knowledge produced by the Minnesota Department of Public Safety. In eighty-three pages of lucid and tight writing, the whole subject is dissected and illuminated. All of the hearsay and the near-truths and the half-truths of the usual discussions of this problem are reduced to simple facts by this precise little booklet. What do they do in Sweden? Precisely what is implied consent? What does the dramshop law provide? What distinguishes a social drinker, a problem drinker, a problem driver, an alcoholic? Does chemical testing for alcohol violate the First Amendment? How much intake is required to produce impairment?

This booklet is a must for any physician treating trauma, for any physician rendering primary care to people over the age of twelve.

The Minnesota State Medical Association participated in this booklet through the person of Dr. James Halvorson. He and the other contributive experts are dedicated to reduction of the drinking-driver accident toll. Their booklet is available free, by request to the Minnesota Department of Public Safety, St. Paul 55101. I highly recommend it to every thoughtful physician who treats either trauma or people.

S. R. Maxeiner Jr., M.D.
Minneapolis, Minnesota

A PHYSICIAN'S LIVING THOUGHTS by Carl Thenebe, M.D.; Philosophical Library, N.Y.; 161 pages; $4.95.

This small book, dealing with the thoughts of a physician, is divided into 16 pauses (chapters). He deals with numerous phases of life—its philosophies, morals, ethics, principles, emotions, and its health. It can provide numerous moments of relaxation while at the same time providing intellectual stimulus.

Carl O. Rice, M.D.

Childrens Hospital" — *Hugh J. Williams, M.D.*

FEBRUARY, 1972

Special Issue
The Childrens Hospital

if skin is infected, or open to infection...

choose the topicals that give your patient–

- broad antibacterial activity against susceptible skin invaders
- low allergenic risk—prompt clinical response

Special Petrolatum Base
Neosporin® Ointment
(polymyxin B-bacitracin-neomycin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 5000 units; zinc bacitracin, 400 units; neomycin sulfate 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q. s.
In tubes of 1 oz. and ½ oz. for topical use only.

Vanishing Cream Base
Neosporin®-G Cream
(polymyxin B-neomycin-gramicidin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 10,000 units; neomycin sulfate, 5 mg. (equivalent to 3.5 mg. neomycin base); gramicidin, 0.25 mg., in a smooth, white, water-washable vanishing cream base with a pH of approximately 5.0. Inactive ingredients: liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax, purified water, and 0.25% methylparaben as preservative.
In tubes of 15 g.

NEOSPORIN for topical infections due to susceptible organisms, as in impetigo, surgical after-care, and pyogenic dermatoses.

Precaution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: Not for use in the external ear canal if the eardrum is perforated. These products are contraindicated in those individuals who have shown hypersensitivity to any of the components.

Complete literature available on request from Professional Services Dept. PML.

A gratifying announcement about Empirin® Compound with Codeine

You may now specify up to five refills within six months when you prescribe Empirin Compound with Codeine (unless restricted by state law).

It is significant in this era of increased regulation, that Empirin Compound with Codeine has been placed in a less restrictive category. You may now wish to consider Empirin with Codeine even more frequently for its predictable analgesia in acute or protracted pain of moderate to severe intensity.

Empirin Compound with Codeine No. 3 contains codeine phosphate* (32.4 mg.) gr. ½. No. 4 contains codeine phosphate* (64.8 mg.) gr. 1. *(Warning—may be habit-forming.) Each tablet also contains: aspirin gr. 3½, phenacetin gr. 2½, caffeine gr. ½.

What Minnesota doctors need is a Malpractice Liability Carrier that won't fade when trouble comes.

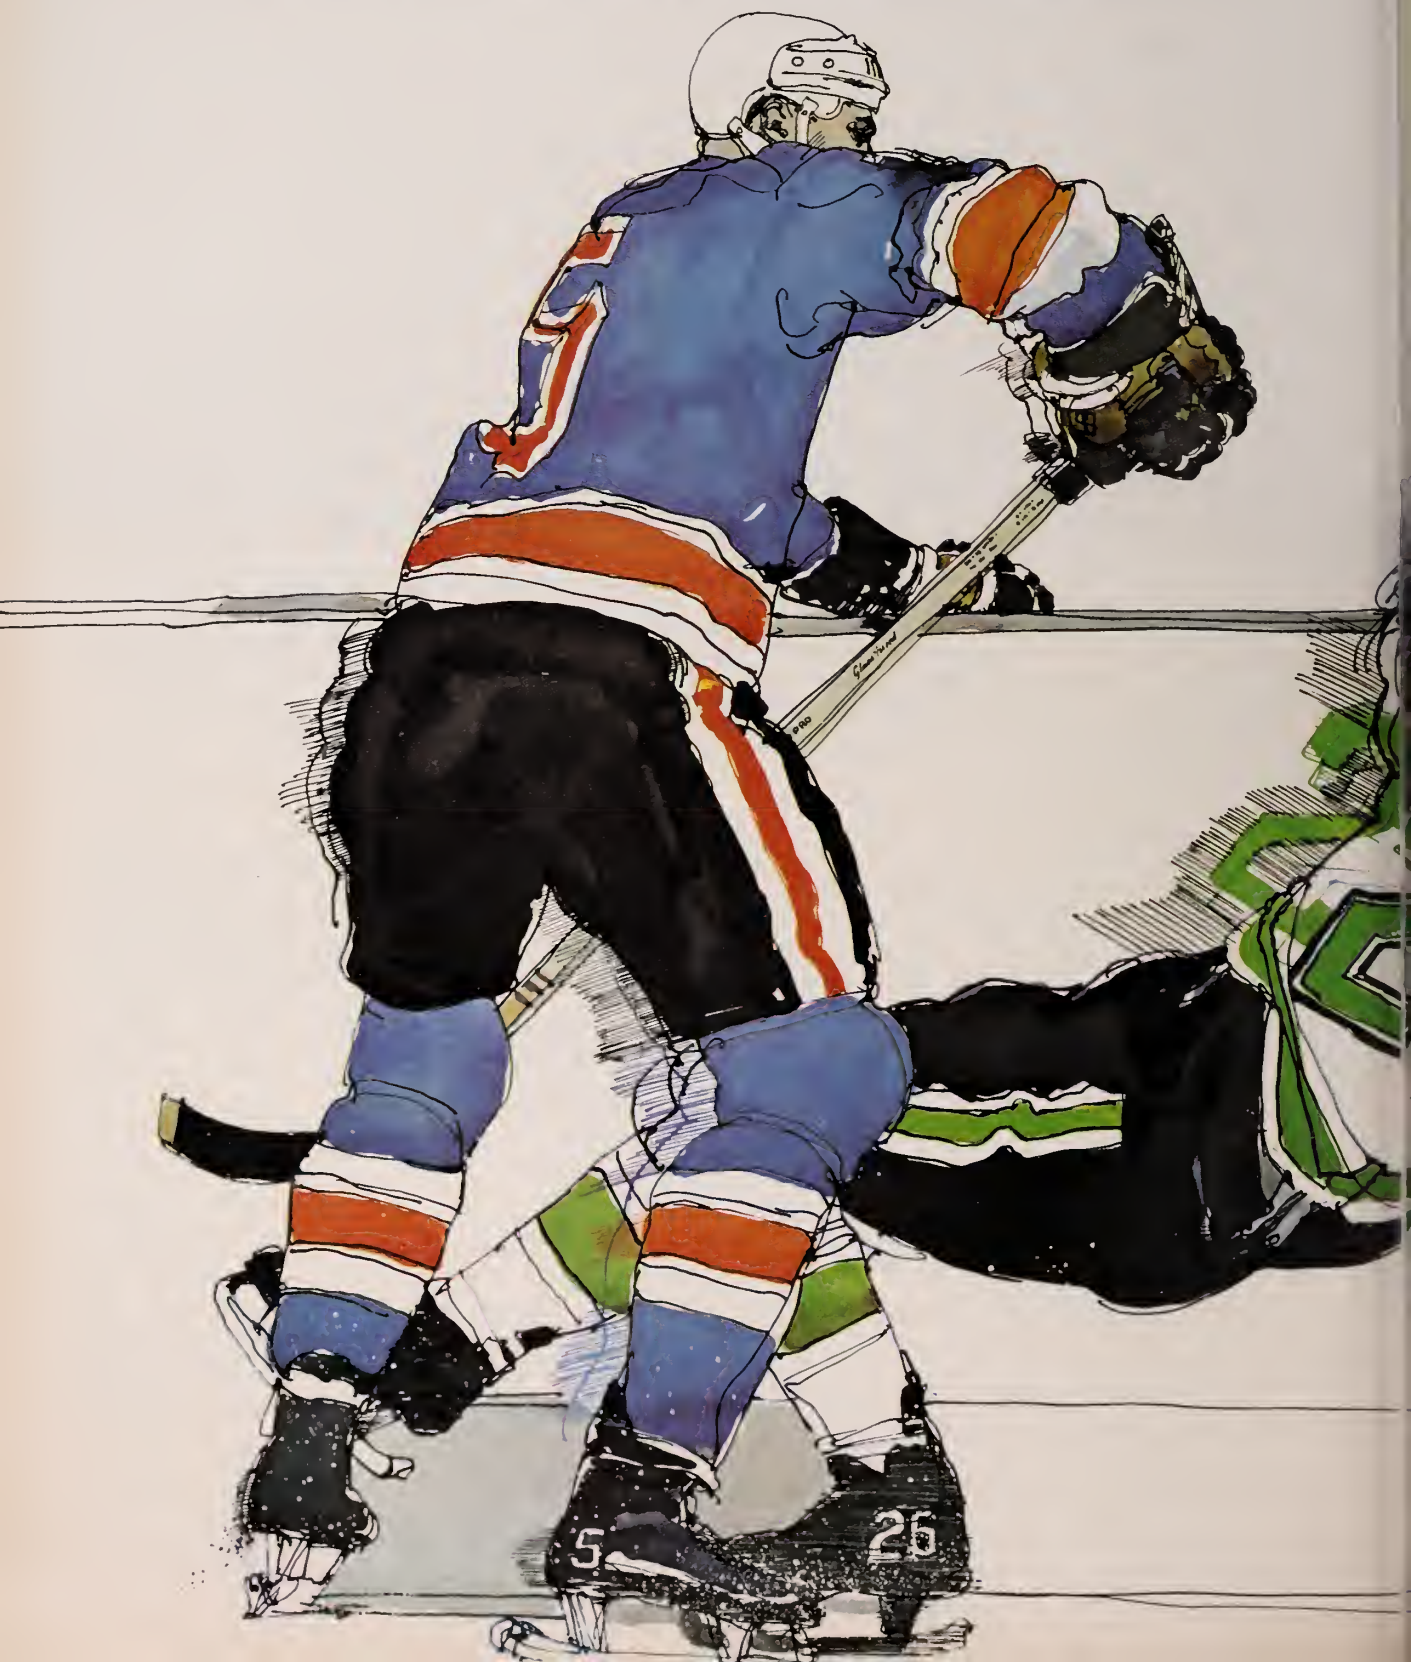
Tandearil® Geigy

oxyphenbutazone NF

tablets of 100 mg.



mportant Note: This drug is not a simple analgesic. o not administer casually. Carefully evaluate patients efore starting treatment and keep them under close upervision. Obtain a detailed history, and complete hysical and laboratory examination (complete emogram, urinalysis, etc.) before prescribing and at equent intervals thereafter. Carefully select patients, voiding those responsive to routine measures, con- raindicated patients or those who cannot be observed equently. Warn patients not to exceed recommended osage. Short-term relief of severe symptoms with ne smallest possible dosage is the goal of therapy. osage should be taken with meals or a full glass of ilk. Patients should discontinue the drug and report mmediately any sign of: fever, sore throat, oral sions (symptoms of blood dyscrasia); dyspepsia, pigastric pain, symptoms of anemia, black or tarry tools or other evidence of intestinal ulceration or emorrhage, skin reactions, significant weight gain or dema. A one-week trial period is adequate. Discon- nue in the absence of a favorable response. Restrict eatment periods to one week in patients over sixty. *ndications:* Acute gouty arthritis, rheumatoid arthritis, heumatoid spondylitis.
ontraIndications: Children 14 years or less; senile atients; history or symptoms of G.I. inflammation or lceration including severe, recurrent or persistent yspepsia; history or presence of drug allergy; blood yscrasias; renal, hepatic or cardiac dysfunction; ypertension; thyroid disease; systemic edema; tomatitis and salivary gland enlargement due to the rug; polymyalgia rheumatica and temporal arteritis; atients receiving other potent chemotherapeutic gents, or long-term anticoagulant therapy.
Warnings: Age, weight, dosage, duration of therapy, xistence of concomitant diseases, and concurrent otent chemotherapy affect incidence of toxic reac- ons. Carefully instruct and observe the individual atient, especially the aging (forty years and over) ho have increased susceptibility to the toxicity of the rug. Use lowest effective dosage. Weigh initially npredictable benefits against potential risk of severe, ven fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.
Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.
Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia, gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angiitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement.

TA-8356-9

WHAT'S THE PENALTY FOR BOARDING?

Ken Dallison

Two minutes in the penalty box for the offender and possibly months of painful skeletal muscle spasm for the victim.

For the skeletal muscle spasm of back sprains, Valium® (diazepam) can be a valuable adjunct. A dose of 2-10 mg, three or four times a day, goes to work to help break up the cycle of spasm/pain/spasm. The resultant relief of skeletal muscle spasm may permit greater mobilization of the affected muscles and may help the patient resume usual activities sooner than otherwise possible.

Paraspinal muscle mass frequently vulnerable to this type of trauma.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

President's Letter

Partnership In Medical Education

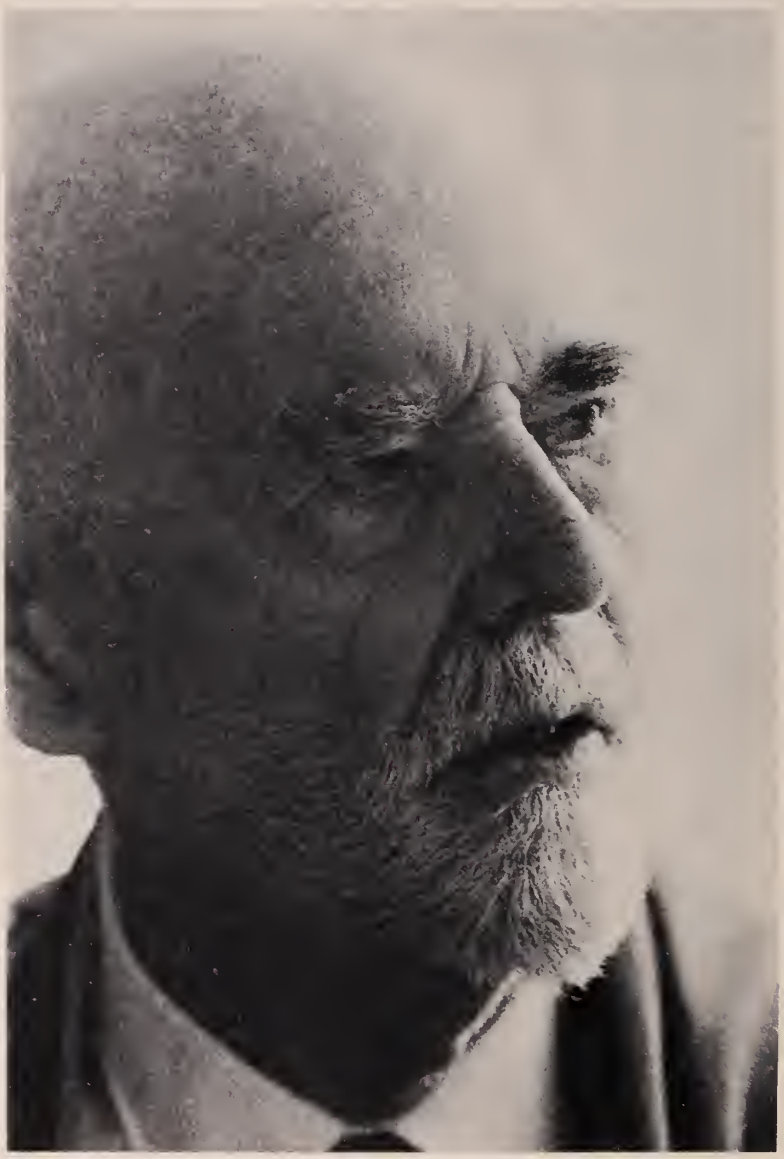
In September, 1972 approximately 225 medical students will begin medical training in Minnesota. This has been achieved by opening two new medical schools: one at Rochester and one at Duluth, as well as the increased enrollment of our present medical school at the main campus.

This increase in potential doctors for Minnesota did not just happen. A great deal of effort was needed from our medical educators, the practicing physicians and our legislators to accomplish this expansion.

Now that this expansion has taken place, the faculties of the three medical schools face a monumental challenge to provide a quality and meaningful training program for these students. This must be done in their undergraduate as well as their postgraduate training programs. The private practicing physician in Minnesota must also assume an active role in helping to provide opportunities for these medical students and residents. He must be willing to participate in new programs as well as educational programs already established.

The Rural Physicians' Associate Program is an example of a new program already in operation. This program has allowed 23 medical students to spend one year of their education working with a rural physician. This program is now six months old and from all appearances, it is an overwhelming success. The student is finding rural Minnesota communities attractive and the learning opportunities to be exceptional. The physicians are enthusiastic and willing to make the sacrifice necessary to insure success of the program and finds the medical student to be intellectually stimulating. The faculty of the Family Practice Department has assumed the responsibility for providing one of their staff members as well as a faculty member from one of the other specialty departments of the University of Minnesota Medical Schools to visit once a month each area where a student is in training. The student presents interesting cases to the visiting faculty and all of the area doctors attend these sessions making them a true educational experience.

This new program is a perfect example of how medical education can be an ongoing achievement not only for the student but for the faculty members and the rural physicians. The more opportunities, such as the Rural Physicians' Associate Program, that exist, the better the medical care will be for residents of Minnesota.



With the increasing number of students both on an undergraduate and postgraduate level, we must continue to provide new and stimulating programs for these young men and women. These programs must be a product of close cooperation of all the physicians of the state. We have just begun this partnership in medical education which I feel is so urgently needed. The potential benefits of this partnership are unlimited.

By developing new programs the quality and availability of medical care to our patients in Minnesota will indeed continue to improve.

Robert T. Kelly

President
Minnesota State Medical Association

Dedicatory

Walter Reeve Ramsey, M.D.

Dr. Ramsey, who graduated from medical school in 1896, and who in 1902 became the first physician in this area to limit his practice to pediatrics, incorporated The Childrens Hospital in 1923. Almost half a century later, on November 8, 1971, Dr. Ramsey celebrated his 99th birthday.

The Childrens Hospital Special Issue

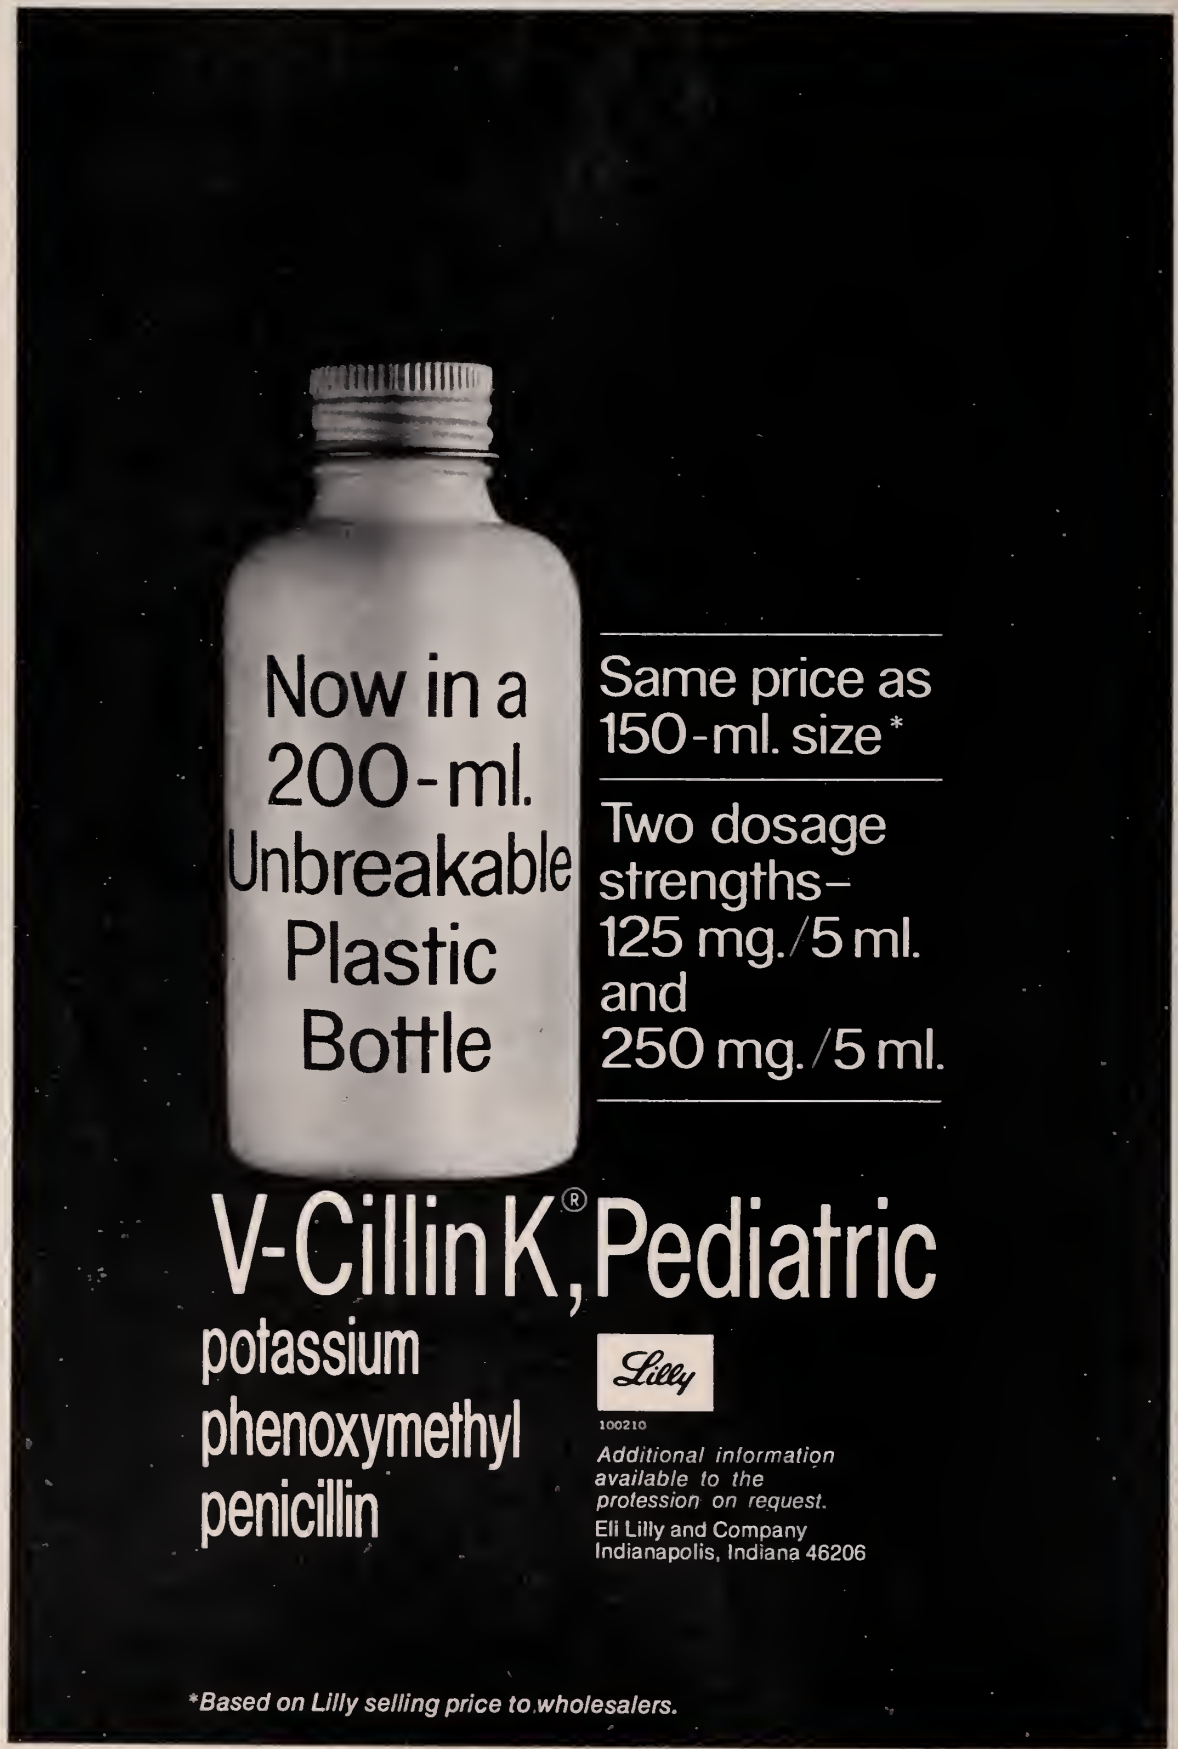
Hugh J. Williams, M.D., Guest Editor
Charles W. Jarvis, M.D., Guest Editor

A Childrens Hospital*

—is a place where infants and children may go and receive the best medical and surgical care known to science.

—must have a staff of physicians, surgeons, nurses, and a personnel especially trained in the field of children.

—need not be large, but must be a model in the things pertaining to the health and welfare of children.



—must be a center of education for physicians, nurses, and the public in the health and well-being of children.

—should be regarded as "a vital institution of health and education in the community," which must be subsidized.

—must maintain its identity, dedicated not only to the best medical and surgical care of children, but to research and the dissemination of knowledge in the things pertaining to the health of children.

Relapse of Meningitis after Ampicillin Therapy

KRISHNA M. SAXENA, M.D.* AND DAVID MAAS, M.D.*

AMPICILLIN HAS BEEN considered the drug of choice for the treatment of meningitis due to Hemophilus influenzae.[1,2] There is no doubt that it is effective and relatively nontoxic and has the advantage of being a bactericidal rather than a bacteriostatic drug. The commonly recommended dose is 150-200 mg/kg/24 hours[1-4] given in four to six divided doses intravenously, and most cases respond well to this dosage.[3,4]

The penetrance of ampicillin into the cerebrospinal fluid is rather poor and the concentrations, even during the acute stage of meningitis, range from approximately 3% to 30% of the serum levels.[3,5] As the inflammation of the meninges subsides, the permeability decreases, and levels in the spinal fluid decrease further. Thrupp et al. found a mean cerebrospinal fluid-serum ratio of 36% on the third day of treatment and 12% on the tenth day or later, with a range of 0 to 100%.[6] Hence, some authors have recommended a higher dosage, from 200-400 mg/kg/24 hours.[7] Over the last four years, we have treated all cases of H. influenzae meningitis with ampicillin in a dose of 400 mg/kg/day. Even with this larger dose we have seen relapse in a child after therapy had apparently produced a clinical and bacteriological cure. In several other children we have observed a delayed clinical response or persistence of fever on ampicillin, which responded promptly within 24 to 48 hours when the antibiotic was changed to chloramphenicol. However, it should be emphasized that the vast majority of approximately 150 children with meningitis treated at The Childrens Hospital during the last four years responded well to ampicillin therapy.

Case Report

First Admission

A four-month-old white male weighing 9 kg., was admitted to Childrens Hospital on November 3, 1969. His illness began two weeks prior to admission with cough, which became progressively worse for seven to eight days. He then developed a fever of 102.8°F and was admitted to another hospital on October 28, with a diagnosis of tracheobronchitis. He was given ampicillin, 125 mg. q.6 hourly I.M. (55 mg/kg/day).

The following day the patient had a generalized seizure. His temperature returned to normal by October 31. At that time he was asymptomatic, and oral ampicillin was started in the same dosage. The next day he again developed fever and, on November 2, the antibiotic was changed from ampicillin to triacetyloleandomycin. He remained febrile and was transferred to Childrens Hospital on November 3.

Physical Findings

On admission the child was found to be lethargic, semiconscious, and responsive only to painful stimuli. He had nuchal rigidity, a firm, bulging fontanelle and a temperature of 102.8°F. The chest, heart and abdomen were normal. No evidence of otitis or pharyngitis was found and the child appeared to be well hydrated. Transillumination of the head was within normal limits.

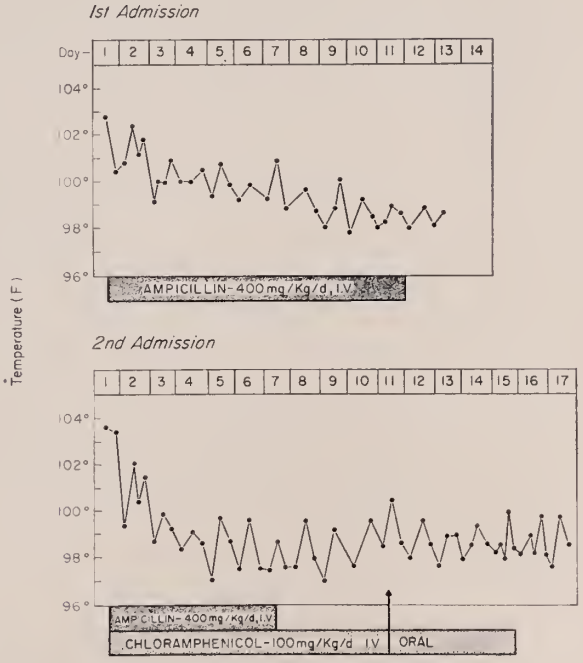

Fig. 1—Hospital course of Patient #1.

*From the Department of Pediatrics, University of Minnesota and The Childrens Hospital, Inc., St. Paul, Minnesota.

His WBC count was 22,000 with 83% neutrophils, 11% lymphocytes and 6% monocytes. Lumbar puncture revealed a cloudy cerebrospinal fluid which was positive for gram-negative pleomorphic rods on smear.

Cerebrospinal fluid from the initial lumbar puncture grew H. influenzae organisms which were resistant to ampicillin by disc sensitivity. Tube dilution studies could not be done. A blood culture drawn at the same time grew H. influenzae group B which was sensitive to ampicillin by the disc sensitivity test.

Treatment

Therapy was started with a loading dose of 1.0 gm. ampicillin intravenously, followed by 400 mg/kg/day in six divided doses. The patient responded well clinically; he was alert and had decreased neck stiffness the following morning. His temperature fell by lysis over several days and was normal by the eighth day of admission (Figure 1). Nuchal rigidity disappeared by the fifth hospital day and his appetite returned to normal. Repeat lumbar punctures done on the fourth and eighth hospital days showed normal sugar and protein and were negative for organisms by smear and culture (Table). He continued to do well clinically and ampicillin was discontinued at the end of the eleventh hospital day, seven days after the cerebrospinal fluid had returned to normal and three days after the temperature became normal. He was discharged well on the thirteenth day.

Second Admission

The child apparently did well at home for the next four days. On the fifth day after discharge, he developed a temperature of 102°F and became very irritable. He was readmitted the following day with a temperature of 103.6°F. Physical examination showed irritability, listlessness, and mild neck stiffness. His fontanelle was soft and flat. Head circumference was the same as before (42 cm.) and transillumination was negative. The rest of the physical examination was normal. His WBC count was 23,000/cmm. with 82% neutrophils, 16% lymphocytes, and 2% monocytes. Lumbar puncture yielded only a small amount of cerebrospinal fluid; therefore cell count and chemistries could not be done. However, a smear showed pleomorphic gram-negative rods and the culture was positive for H. influenzae group B. He was again given a loading dose of 1.0 gm. ampicillin intravenously, followed by 400 mg/kg/day in six divided doses plus chloramphenicol, 100 mg/kg/day in four divided doses.

The day following admission the child was still listless, but by the third day he was afebrile, alert and eating well. On the fifth day his WBC count was 9,300/cmm. with 12% neutrophils, 79% lymphocytes, 6% monocytes and 3% eosinophils. The child was clinically normal for the rest of his hospitalization. Repeat lumbar punctures done on the third, eighth and seventeenth hospital days were negative on smear and culture. The other findings are shown in the Table.

Ampicillin was discontinued after six days but chloramphenicol was continued intravenously for 10 days and then orally in the same dose for another five days. He was discharged after 17 days of hospitalization. Followup examinations at one week, six weeks and six months after discharge were completely normal.

Discussion

The studies of Mathies[4] and of Barrett et al.[3] have established ampicillin as the drug of choice for H. influenzae meningitis. No strains resistant to ampicillin have been reported to date.[8] In-vitro studies show almost all strains sensitive to levels greater than 0.78 mg/ml. and most to levels greater than 0.39 mg/ml. of ampicillin.[3,9] The levels of ampicillin in the cerebrospinal fluid, after 150 mg/kg/24 hours were given intravenously every four hours, ranged from 0.03 to 7.00 mg/ml.,[6] but in the majority of cases they reached bactericidal levels. Although a disc sensitivity test does occasionally show resistance to

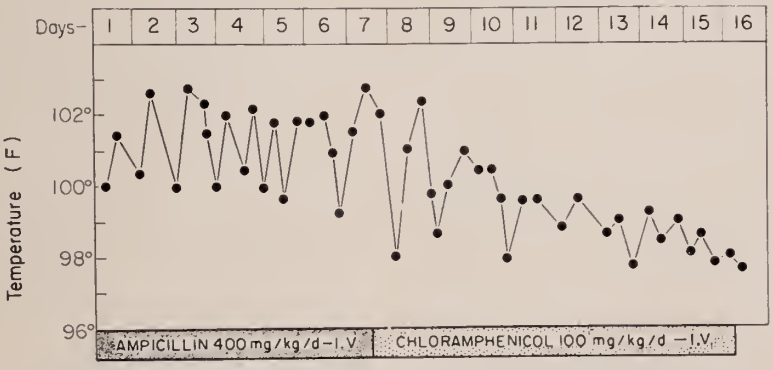
12-5	23	4	96	21	41	Neg.	Neg.	

ampicillin, the more reliable tube dilution test has not borne this out.[8] Nevertheless, at least 10 cases have been reported in the literature where the child either did not respond well to treatment or had a relapse of meningitis during or after the completion of a course of therapy with ampicillin.[10-18]

Seven of the 10 children has been treated with ampicillin in a dose of 200 mg/kg/day or less. The other three received between 200-300 mg/kg/day.[16,17] In our case the dose was 400 mg/kg/day for the entire period of therapy.

Sequestered Areas of Infection



It is conceivable that localization of infection in a sequestered area may hinder penetration of the antibiotic and allow organisms to proliferate. Subdural effusions or 'orbital cellulitis' was found in several reported cases.[10,15,17] No such localization or latent focus of infection, e.g., otitis, mastoiditis, subdural effusion, was observed in our patient. Nor did the child manifest any other complication of H. influenzae infection to acount for the relapse of meningitis.

Approximately 150 children with H. influenzae meningitis have been treated with ampicillin during the last four years at The Childrens Hospital.[19] Because of the relatively poor penetrance of ampicillin into the cerebrospinal fluid, we have routinely used a dose of 400 mg/kg/day intravenously in four to six divided doses. In five children, chloramphenicol was used when the response to ampicillin was unsatisfactory.

In the first child described in this report, chloramphenicol was given for the treatment of relapse of meningitis. In two other children, the temperature continued high for five to seven days despite the fact that the cerebrospinal fluid cell count, sugar and protein showed improvement. No other complication or cause for fever was found and the temperature dropped to normal within two days of starting chloramphenicol. In two additional patients, although the cerebrospinal fluid cell count and protein decreased, the sugar persisted at a very low level (5 and 8 mg/100 ml. respectively) and temperature remained high for five to six days after ampicillin therapy was begun. The blood sugar was normal in both cases. Therapy was changed to chloramphenicol and, within 24 to 48 hours, the cerebrospinal fluid sugar rose up to normal in both patients. It must be pointed out that in all these four patients, the smear and cultures of cerebrospinal fluid, as well as blood cultures, became and remained negative after the initial ampicillin treatment.

Chloramphenicol

In light of the preceding observations, we feel that ampicillin is effective in most cases of H. influenzae meningitis in children and must be the initial drug used. However, treatment failures do occasionally occur; chloramphenicol may then have an important place in the treatment of such cases.

Dose

For obtaining optimal response to ampicillin, a relatively high dose of 400 mg/kg/day intravenously (given in four to six divided doses) seems to be indicated. We have not encountered any significant side effects from this dose. Therapy should be prolonged, especially if the child had been ill for several days before diagnosis was made or had received partial or inadequate antibiotic treatment for other illnesses.

Dangers

The dangers associated with chloramphenicol are well known. Nonetheless, in certain special circumstances its use may be justified. One of its main advantages is its ready diffusibility into the cerebrospinal fluid. The following conditions should be considered as possible indications for chloramphenicol in patients with H. influenzae meningitis:

1. Hypersensitivity to penicillin. 2. Failure of cerebrospinal fluid sugar to come up to normal after three days of adequate therapy with ampicillin in the presence of normal blood sugar. 3. Failure of temperature to return to normal within five to six days in the absence of complications. 4. Relapse of meningitis after successful response to therapy with ampicillin.

Conclusion

A patient with H. influenzae meningitis who developed a relapse after ampicillin therapy was treated with chloramphenicol during the relapse and responded promptly. At six months follow-up, he was quite normal. While ampicillin is the drug of choice in H. influenzae meningitis, chloramphenicol may be indicated in certain special circumstances.

Maintenance Fluid Requirements

of Small Infants

JOHN W. REYNOLDS, M.D.*

THE MAINTENANCE water requirement for the patient under treatment is defined as that required to replace the insensible water loss (skin and respiratory tract evaporation) and urine formation in the afebrile patient at bed rest, receiving nothing by mouth, and with minimal alimentary tract losses. It is also assumed that the patient is receiving enough calories, usually via intravenous glucose, to prevent ketosis and to limit the catabolism of endogenous protein.

Fluid Requirements and Metabolic Rates

Throughout most of childhood and adulthood, the water and electrolyte requirements are proportional to the body surface area, 1500-2000 ml. per square meter per day. However, the use of body surface area does not have a good physiologic basis[1] and its usefulness depends on the generally good correlation of the metabolic rate with the surface area. Unfortunately, this correlation with surface area does not hold for newborn infants, as will be discussed below.

Insensible Losses

The metabolic rate, an expression of the magnitude of heat production, is the primary determinant of maintenance water requirements. Insensible water loss through evaporation from the skin and respiratory tract is a major means of ridding the body of heat and thus maintaining a constant body temperature. At all ages, approximately 24% of basal heat loss is through evaporation. The metabolic rate and the volume of the insensible losses are closely related in that the insensible losses are approximately 45 ml. per 100 Calories expended. This volume includes 30 ml. as skin losses and 15 ml. as respiratory tract losses.

*Department of Pediatrics, University of Minnesota and The Childrens Hospital, St. Paul, Minnesota.

See editorial, page 137.

Urine Volume

The kidneys are required to excrete about the same load of solutes, mainly protein breakdown products such as urea, per unit of heat production at all ages. Therefore, the metabolic rate determines to a great extent the amount of endogenously produced solute load presented to the kidneys under basal conditions. As water is required for the excretion of these solutes, and the greater the solute load, the larger will be the volume of water required at any given urine osmolality, the metabolic rate is an important determinant of urine volume.

The renal solute load during parenteral therapy in a basal state is approximately 20 mOsm per 100 Calories.[2,3] For this amount of solute to be excreted in a urine of the same osmolality as plasma, 285 mOsm per l., 70 ml. of water would be required. Thus, the water requirement for formation of nonconcentrated urine is about 70 ml. per 100 Calories expended. If urinary concentrating ability is intact, less water would be needed, but in many ill infants the ability to produce a urine osmalality above that of plasma may be impaired. Small amounts of water may be lost in normal stools but are probably balanced by the water of oxidation, 12 ml. per 100 Calories expended, which is produced in the body as a by-product of the metabolism of foodstuffs or products of body catabolism.

Summary

The maintenance water requirements in a basal state are 45 + 70 = 115 ml. per 100 Calories expended. Because most patients, including sick infants, are not resting quietly at all times and thus are not in a truly basal state, the requirement should be increased by 50%. Under the conditions described above, the requirement

would thus be increased to 170 ml. per 100 Calories. This increase will cover variations in activity level, small amounts of sweating which may occur, and variations in the production of the endogenous renal solute load.

Neonatal Metabolic Rate

In the first week or weeks, the caloric expenditure per square meter of body surface area and per unit of body weight is much lower than later in life. This has been known for many years,[4] but the physiological bases, a difference in body composition and a lower metabolic rate of the major body organs, were not understood until recently.

Body Composition

In newborn infants, especially in prematures, metabolically inactive water makes up a much higher proportion of the total body mass than in the older infant or child.[5] The proportions of water and the various metabolically active tissues change rapidly during the neonatal period, leading to changing metabolic rates per square meter or per kg. depending on the age of the infant and his size and maturity at birth. The body fraction whose variation most influences the changing metabolic rate is the extracellular fluid.[6]

Lower Metabolic Rate of Major Organs

The other reason for the relatively low metabolic rate of the newborn infant is a lower metabolic rate per kg. of brain, liver, heart and kidney before one month of age than after.[7] Since these organs are the main sites of oxygen consumption in the newborn, their metabolic rates essentially determine the metabolic rate of the whole infant.

Summary

The low metabolic rate per M^2 or per kg. in the neonate is due to the high fraction of the body mass made up by water, and therefore the relatively small fraction of body mass made up by actively metabolizing organs; and the relatively low metabolic activity of these organs as compared with their metabolic rates one month later. The increasing metabolic rate per M^2 or per kg. during the first one to two months of life, therefore, is due to the increasing proportion of the weight made up by metabolically active organs and the increasing metabolic activity of the organs themselves.

Oxygen Consumption and Calorie Production

Calories produced can be calculated from O_2 consumption, using the average value of 4.83 Calories per liter of O_2 consumed. At an abdominal skin temperature of 96-96.5°F (the neutral range), the newborn in the first few days of life can be considered to be in a basal state and the O_2 consumption is 4.5-5.5 ml./kg./min. in premature, full-term infants and infants with intrauterine growth retardation.[8,9] The O_2 consumption rises with increasing age in all infants, is consistently lowest in the smallest prematures and is highest in infants with intrauterine growth retardation. At age seven to 14 days, the O_2 consumption is roughly 7 ml./kg./min. and by one to two months is about 9 ml./kg./ in prematures.[9] These figures are in contrast to findings in full term infants of O_2 consumption of about 7 ml./kg./min. from two weeks up to one year of age.[10] O_2 consumption data have been transferred into values for heat production (Cal./M^2/hr.) by Hey and Katz[11] who showed that in prematures of 1.8-2.1 kg. birthweight, heat production rose from about 22 Cal./M^2/hr. on Day one to 25 Cal./M^2/hr. on Day 10 and 30 Cal./M^2/hr. on Day 20. In smaller prematures, of 0.9-1.2 kg. birthweight, the heat production values at the same ages were 16, 20, and 25 Cal./M^2/hr.

TABLE

			Basal Metabolic Rate			Maintenance volume based on 170 ml per 100 Cal. expended

*Surface area (M^2) = 0.1 x wt. $(kg.)^{2/3}$

†Liter of O_2 consumed yields 4.83 calories.

Causes of Increased Oxygen Consumption

Most importantly, a fall or rise in the temperature away from the neutral range leads to increased O_2 consumption. A fall in the skin temperature leads to an increased heat production and O_2 consumption, but this is not reflected in an increased evaporative water loss unless the baby begins to cry.[12] The lack of an increase in evaporative water loss is probably due to peripheral vasoconstriction, acting as a heat conserving mechanism. Thus, the increased rate of metabolism with cold stress is not associated with a parallel increase in water requirement. Infants showing intrauterine growth retardation have a higher O_2 consumption per kg. than other infants matched for both weight and gestational age.[9,13] This may be due to a decreased body water content and thus a preponderance of metabolically active organs, and perhaps due to a heightened metabolic activity as a post-malnutrition recovery phenomenon. There is much variability among such growth retarded infants but the increase in O_2 consumption in one series was 17% over that predicted from the weight, with many infants showing a 30-50% increase over predicted values.[13]

Causes of Decreased Oxygen Consumption

Oxygen consumption may be significantly low in severe hypoglycemia (4.0-4.3 ml./kg./min.) and in severe icterus with lethargy.[14] In infants with the respiratory distress syndrome, O_2 consumption is low (mean - 4.3 ml./kg./min.) during the first two days, then rises to above normal levels of 8-10 ml./kg./min. at four to five days, before return to normal (5-7 ml./kg./min.) at seven days.[15] Thus, during the early period of marked cardiorespiratory effort, the O_2 consumption is low.

Recommendations

The following examples (Table) of the calculation of maintenance water needs are based on the preceding discussion and the data presented. Hopefully, the physiological bases of the calculations are clear enough that the reader may modify the figures if new metabolic rate data become available.

Several recommendations can be derived from the examples presented:

1. In the first two to three days, the maintenance water requirements are 60-70 ml./kg./d.
2. Water needs rise through the first week and level off at 80-90 ml./kg./d.
3. In infants with intrauterine growth retardation and some prematures one to two month old, water requirements may go to 100-110 ml./kg./d.
4. The use of the common rule of 1500-2000 ml./M^2/d. may lead to significant overhydration in infants under one month of age.

The water solutions administered intravenously in the neonatal period should contain 10% glucose because of the frequent occurrence of hypoglycemia in ill newborns. An electrolyte free solution is administered for the first two to three days of life because ill newborns commonly require $NaHCO_3$ treatment of metabolic acidosis and Na^+ overloading is a frequent problem. Thus, they do not need further Na^+ as part of the maintenance fluids. Serum K^+ is frequently high as a result of neonatal hypoxia and acidosis and thus K^+ administration is not advised. After three days of age, the fluids used should contain approximately 20 meq. per 1. Na^+ and 20 meq. per 1. K^+ as the chlorides[2] or a portion of the anions may be a metabolizable organic anion such as acetate, lactate or bicarbonate.

Conclusion

Maintenance water and electrolyte requirements for infants in the first month of life cannot be calculated from the ml. per M^2 or ml. per kg. values used in planning therapy for older infants and children. Differences in body composition and metabolic activity of major body organs between newborns and older infants make essential the use of caloric expenditure, or metabolic rate, as the basis for calculating fluid requirements. Recent extensive data on caloric expenditure of premature, growth retarded, and full-term infants allow a more precise definition than previously possible of neonatal requirements. Using the value of 170 ml. required per 100 calories expended, neonatal maintenance water requirements are 60-70 ml./kg./d. in the first two to three days and rise to 80-90 ml./kg./d. by one week.

Urinary Bladder Capacity

The Clinical Importance in Children

ROBERT W. GEIST, M.D.; STANLEY J. ANTOLAK, M.D. AND
EDWARD J. RICHARDSON, M.D.

WE SEE TWO KINDS of voiding problems in children. Some void infrequently and are troubled with urinary tract infections; others without infections void too frequently and are troubled with numerous other urologic problems.[1] Presumably some of these symptoms are related to bladder size.

In 1968 we were particularly interested in the differential diagnoses of children having frequency, urgency sometimes to incontinence, and/or enuresis.[1] We found a variety of problems associated with these "small bladder" symptoms, but the number of patients actually having small bladders was difficult to assess since no normal values for bladder size at cystoscopy under general anesthesia were available for comparison. For this reason measurements of bladder capacity were made on 312 children referred for a variety of urologic complaints.*

Three useful observations are made from this data: (1) In the average the size of the bladder was found to be larger in children with urinary infections. (2) Over-sized bladders occurred as frequently in younger untrained children as in older children, suggesting that a larger bladder is congenital and not acquired through training or habit. (3) Children having so-called "small bladder" symptoms were seldom found to have small bladders. Patients with frequency, urgency, incontinence or enuresis or both were found to have a variety of urinary tract pathologies.

Materials and Methods

Bladder capacity was measured in 312 children during 338 consecutive cystoscopies under general anesthesia from December, 1968, to December, 1970 (Table 1). Twnety-six children did not have their capacity measured for one reason or other: when acute cystitis was found; when reflux with recent infection was known; when anesthesia was of inadequate depth; or when there was oversight on the part of the examiner.

TABLE 1
Reasons for Cystoscopy in 338 Children

A pressure of 70 cms. of water was arbitrarily chosen to measure the bladder capacity. This pressure was in excess of normal resting and voiding pressure and, theoretically, measured the distensibility of the sol-gel material composing the bladder wall. The bladder can be distended more at higher pressures, but using pressures close to bladder rupture is clinically inadvisable. A pres-

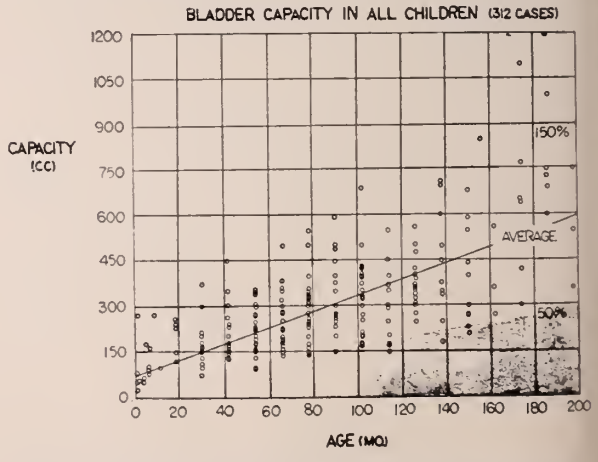

Fig. 1—Average capacity at age five years, six months is 250cc. There is an increment of approximately 30 cc. to bladder capacity per year of age.

*The values obtained are only meant to be useful for comparison until some investigator measures the bladder capacity in a sample of normal children.

See editorial, page 136.

sure of 70 cms. of water proved safe in all cases and served adequately for therapeutic dilation of the bladder in cases of interstitial cystitis.[1]

Results

Average Bladder Capacity

The average bladder capacity for all children under age one to sixteen is estimated by a line in Figure 1. The actual average capacity at each age is noted in Table 2 and compared with that estimated from Figure 1.

Large Bladders

We arbitrarily chose 150% of average capacity (the upper shaded area in Figure 1) to represent an unusually large bladder, but we suspect that a correlation with infrequent voiding history would reduce this percentage and increase the actual number of children having unusually large bladders. We are specifically avoiding a mathematical definition of "megacystis" in this paper. Ten percent of all children (32/312) had these large bladders, and *nearly all with large bladders had infections (28/32).* The decrease in resistance to infection with infrequent voiding is well known.[2]

In children with infections the percentage with oversized bladders age two and under was 28.6% (10/35) and 16.4% (18/110) in children who were trained. This suggests that we are born with and do not acquire unusually large bladders.

Small Bladders

Children having bladders 50% of average size (the lower shaded area of Figure 1) were arbitrarily said to have unusually small bladders. Only 14 of all 312 (about 5%) had truly small bladders, and in only four was this the only apparent cause of diurnal symptoms. Six children had enuresis only, three had interstitial cystitis with clearing of all symptoms after therapy and without change in bladder size, and one had a neurogenic bladder.

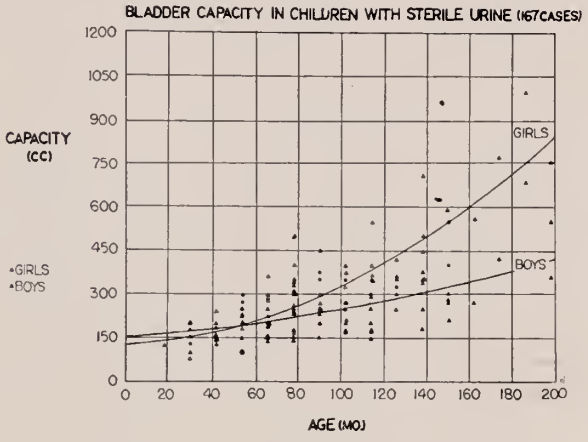

Fig. 2—There is little difference in bladder size until puberty is approached, at which time the rate of change in girls' bladders is greater than in boys. Quadratic equations have been used to emphasize this point.

Sex and Bladder Size

A general average capacity is useful before puberty since girls and boys do not differ much before then. We have attempted to emphasize this visually in Figure 2 by using quadratic rather than linear equations for a line to best represent the data on each sex. Children with sterile urine were chosen for this comparison since, as noted above, an infected population introduces a predominately female group with unusually large bladders. This would act to distort the true relationship when one considers that the proportion of infected girls with large bladders (25/127 or 19.1%) was the same as the proportion of infected boys with large bladders (3/18 or 16.1%).

Average Bladder Capacity in Children Having Infection

As noted above, children having unusually large bladders are over-represented in the urologic population. They have a proclivity to develop infections because of infrequent voiding. Twenty percent (28/145) of children with infections had these unsually large bladders, thus raising the average size in this group (Figure 3). For instance, at age five the bladder averages about 75 cc. larger when infected than when sterile.

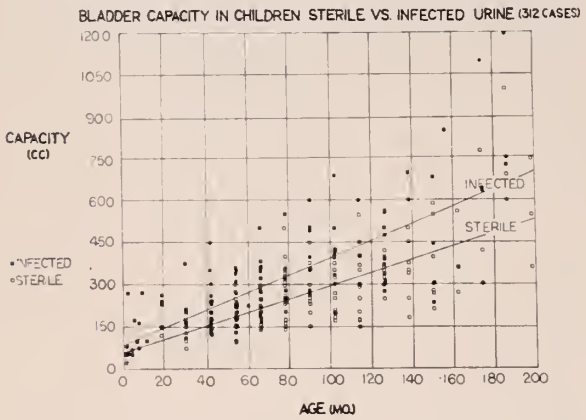

Fig. 3—The average capacity in children with infected urine is raised due to inclusion of a number of children having unusually large bladders. The children with excessively large bladders are over-represented in a urologic series by their proclivity to acquire a urinary infection due to infrequent voiding.

Average Bladder Capacity in Children Having Sterile Urine

This group consisted of 167 children. Only 26 had no bladder symptoms and were usually investigated for asymptomatic hematuria. The other 141 had diurnal symptoms of frequency, urgency sometimes to incontinence ("small bladder" symptoms) and/or enuresis (Table 3). The average capacity in this group was about 14% less than the general average. Ten percent (14/141) of children having sterile urine and bladder symptoms had unusually small bladders and, as noted above, in only four of them did this alone seem to explain their diurnal symptoms.

Discussion

The data suggest that it is not good to be born with too large a bladder, because if one voids infrequently the chances of infection are increased. Cox and Hinman,[4] O'Grady and Cattell[2] and Boen and Sylvester[5] have clearly shown the decrease in urinary tract resistance to infection associated with infrequent voiding. Lapsides[6] has documented this important factor clinically in both adults and children. This study confirms the fact that patients with infections frequently have too large a bladder. In addition, this study shows that unusually large bladders occur in children age two and under. Large bladders in these younger children, found well before training is started, could mean that such bladders are congenital and not acquired through laziness, poor training habits, or cultural expectations, as we have recently seen reported in the popular press.

A pattern of care for a child with urinary tract infection is not complete unless the bladder capacity and consequent voiding pattern are known. At least 20% have unusually large bladders and an unknown percent, an inadequate fluid intake. Where a bladder is large it is mandatory to check the child's urine for infection at frequent intervals until he or she can be trained to void with adequate frequency and to increase fluid intake. Training before age seven is not often possible. After age seven the susceptibility of these children to infections would indicate the need for continued surveillance of the urine at regular but longer intervals.

The 141 children with "small bladder" symptoms and sterile urine had a large variety of pathologies but not often an unusually small bladder (Table 3). For instance, a small bladder alone explained the symptoms in only four children; and a small bladder, though present in six children with enuresis, was unaccompanied with diurnal symptoms. Interstitial cystitis and ureteral reflux were the most frequent causes of an abnormal voiding pattern. The large group of 32 with diagnosis "etiology obscure" deserves attention: A few of them probably had interstitial cystitis but were unresponsive to a single therapeutic bladder dilation at 70 cms. of water, and by strict definition were grouped without a definitive diagnosis[1]; others in this group had hyperactive bladders and responded well to antispasmodics[7]; and a few may have had subclinical neurogenic bladders as suggested by Dorfman et al.[8]

Pitfalls Dependent On Bladder Size

Pitfalls for our pediatric patients with urologic problems are in part dependent on their bladder size.

Neglect

Those children with bladders larger than average will be prone to urinary tract infections and may be subject to urologic neglect if proper surveillance of their urine and proper voiding patterns are not initiated. They may also be erroneously advised that a large bladder capacity was acquired by poor training or laziness: a fact refuted by the data in this paper on children age two and less.

Eroneous Emphasis

Ignoring bladder size as a factor in females with urinary infections may lead one to overemphasis of other factors such as bladder neck or distal urethral band obstructions. Recent data from Smith[9] and Immergut[10] questioning the prevalence of those "obstructions" will help redirect attention to other factors. One of these is bladder capacity as emphasized in this study.

Lack of Parental Insight

Those children with "small bladder" symptoms of frequency, urgency to incontinence and/or enuresis may be neglected by being treated with antispasmodics or by being advised that they will "outgrow" their problems, when a thorough urologic evaluation may reveal many different pathologic conditions. The most dangerous of these are ureteral reflux and posterior urethral valves (Table 3). These children are often subjected to parental hostility for their "lack of control" or laziness. Insight into their problems will be gained only from accurate urologic data.

Summary

Bladder capacity was measured in 312 children at a standardized pressure under general anesthesia.

The average bladder size is raised in those children with infections due to inclusion of a group with unusually large bladders having a tendency to develop infections because of infrequent voiding. The increased likelihood of infections in children having oversized bladders necessitates training them to *void more frequently* and necessitates prolonging their clinical surveillance for recurrence of infection.

Oversized bladders are congenital and are not acquired through poor training or other cultural factors.

Those *children with "small bladder" symptoms seldom have a small bladder,* but usually have other urinary tract pathology amenable to specific therapy.

Bronchial Asthma

Treatment of the Acute Attack and Status Asthmaticus in Children

EDWARD L. STREM, M.D.,* SOL AUSTRIAN, M.D.,* RICHARD E. SAND, M.D.,*
and R. JAMES VACCARELLA, M.D.*

BRONCHIAL ASTHMA and its complications account for 12% of the medical admissions at the Childrens Hospital (4,521 of 37,481 admissions over a ten-year period ending July 31, 1970). In addition to this, many children were seen in the emergency room because of asthma.

Acute Bronchial Asthma

Emergency Room Care

The drug of choice in treating the acute asthmatic attack is aqueous epinephrine. This is given in small frequent doses subcutaneously. As a general rule, we give 0.10 ml. to a child up to 30 pounds and 0.20 ml. to a child 30 pounds or above. This is repeated in 20 minutes, and 20 minutes following the second injection, we give 0.15 to 0.20 ml. of a longer acting epinephrine, Sus-Phrine.®† The importance of the two "priming" doses of aqueous epinephrine cannot be overemphasized. Occasionally, a patient cannot tolerate epinephrine because of untoward side effects. In such cases, Bronkephrine® may be used in doses twice that of epinephrine.

If, during an observation period of 45 minutes to one hour, the patient clears completely, or to a degree that we can anticipate continued oral medications to be adequate, he is allowed to return home. It is important to instruct the mother to give either oral or rectal antiasthmatic drugs for at least 24 hours following an acute asthmatic attack requiring epinephrine. Tedral,®# Marax,®§ or similar drugs may be given orally every four to six hours, or an aminophylline suppository (Aminet®)£ every eight to twelve hours may be used rectally. Follow-up examination within this period of time is also imperative.

Intravenous aminophylline, injected very slowly over a 10-15 minute period (5 mg/kg) may be safely and effectively used in the emergency room. In the very young, it should be used with caution.

Occasionally we see a child with severe paroxymal coughing or an acute attack of dyspnea associated with hyperinflation and decreased breath sounds but no audible wheezing. These can be manifestations of asthma and, when present in a known asthmatic patient, should be treated similiar to the acute asthmatic episode, as outlined above.

If the patient does not respond to the above described series of epinephrine injections, he should be hospitalized immediately because he is either in status asthmaticus or "impending status." The response to outpatient treatment with epinephrine is the most important factor to consider in evaluating a patient for possible hospitalization. Any one or combination of the following factors can be considered critical enough to warrant in-patient care in spite of what seems to be an adequate response to epinephrine: (1) duration of the acute asthmatic episode, (2) cause and severity of previous attacks, (3) reliability of parents, (4) ability of the patient to take and retain oral medications, fluids, and nourishment, (5) presence of infection (pulmonary or extrapulmonary), (6) state of hydration, (7) ventilatory state (atelectasis?, degree of hyperinflation), (8) current or previous steroid therapy, (9) pollution or pollen index, and (10) current weather conditions, especially unstable atmospheric pressure.

FOR CORRECTION SEE

Hospital Care

In a child with asthma, who is considered clinically "brittle," it is best to lean toward the side of hospitalization for observation until one is sure that he has responded to medication and has recovered from the acute episode.

The rationale for treatment is based on the pathogenic factors that contribute to the acute asthma syndrome: (1) edema of the mucous membrane of the bronchi and bronchioles, (2) hypersecretion of a thick, tenacious, viscid secretion, and (3) spasm and contraction of smooth muscle.

The treatment regimen is designed to provide bronchodilatation and adequate hydration, prevent hypoxia, and thereby prevent the development of status asthmaticus.

Bronchodilatation is maintained by small repeated doses of epinephrine as described previously. The "epinephrine series" may be given every four hours if necessary. Oral or intravenous xanthine derivitives (theophylline, aminophylline) may be used, which, because of their site of action, can augment the effectiveness of epinephrine. Occasionally isoproterenol by inhalation is used.

Adequate hydration not only helps prevent the development of acidosis but is the best method of thinning secretions and preventing further inspissated mucous in the bronchi. Often, especially in the younger age group, this can only be accomplished with intravenous fluids. Expectorants such as saturated solution of potassium iodide or glyceryl guaiacolate are of limited value.

Hypoxia is prevented by providing humidified oxygen via mask or tent. If a tent is used, care must be taken to assure adequate oxygen levels.

Infection, if present, is treated with indicated antibiotics. Appropriate cultures should be obtained before starting antibiotic therapy, but in the acute asthmatic episode, when infection is so common, antibiotics should not be withheld while awaiting culture reports. As in any organ system where there is stasis and obstruction, infection is likely. Furthermore, infection is often the cause of the acute attack or can be the main reason for the continuation of the acute episode in spite of what seems like adequate therapy.

Precautions to be followed during the acute asthmatic attack: (1) no tranquilizers or respiratory depressant sedatives should be used, (2) antihistamines should be avoided because of their atropine-like, drying effect. This tends to inspissate secretions even more and enhance the possibility of obstruction with resultant atelectasis, (3) the use of mist tents is contraindicated as this "fog" often causes further bronchoconstriction and/or increases apprehension in an already agitated child.

Status Asthmaticus

A patient is in status asthmaticus if he no longer has a bronchomotor response from epinephrine and is considered to be "epinephrine fast." Such a child is in acidosis which is one of the reasons why there is no bronchomotor response to epinephrine.[1] In children, there is metabolic acidosis due to ketonemia induced by poor caloric intake, inadequate fluid intake, and hypoxia. Dehydration contributes to thickening of the bronchial mucous secretions rendering them dry, tenacious, and viscid which causes them to inspissate and obstruct the bronchi. Edema of bronchial mucous membrane and constriction of bronchial smooth muscle add to bronchial obstruction. As a result of these factors, alveolar hypoventilation occurs with accumulation of CO_2. This increases the pCO_2 with lowering of the pH and results in respiratory acidosis. Other factors of a non-specific nature in the lungs that can play a role are areas of pneumonitis with accompanying cellular exudate in the small bronchi and bronchioles, areas of atelectasis, or even pneumomediastinum or pneumothorax.

In early status asthamticus, there are many normal ventilating alveoli as not all of the bronchial tree is involved. Also many areas of the lungs are hyperinflated resulting in decreased lung compliance. This leads to an uneven ventilation perfusion ratio in various regions of the lung. As a result, the CO_2 tension rises and the O_2 tension falls in the blood perfusing hypoventilated alveoli. However, because an increased amount of CO_2 can be removed by hyperventilation of the less affected alveoli and since the pCO_2 of "shunted" venous blood is little greater than that of arterial blood, the CO_2 tension of arteriolar blood is usually normal or below normal (hypocarbia). In contrast, similiar compensation for a low oxygen tension does not occur and hypoxemia results. As more airways become obstructed, the total volume of hyperventilation becomes insufficient to maintain a normal pCO_2 and hypercapnia occurs. Therefore, in well-estab-

lished status asthmaticus there is hypercapnia, hypoxemia, and acidosis.[2] In the early stages, because of hyperventilation of relatively unaffected alveoli, pCO_2 may be normal or low, pH may be normal, but pO_2 will be low.

Treatment of Status Asthmaticus

All patients in status asthmaticus are in respiratory distress and without exception should be admitted to the hospital, preferably into an intensive care unit.

Humidified oxygen is given immediately either by mask or tent in which there is 40-60% ambient oxygen. It should be given continuously to keep the pO_2 above 65mm. of mercury.

Arterial blood gas determinations are performed immediately including pH, pO_2 and pCO_2. Serum electrolyte determinations (sodium, potassium, CO_2 content, and chloride) and serum osmolality should also be done. If capillary blood is used for pH, the pCO_2 can be determined from the pH and CO_2 content on a nomogram. The pH, pCO_2 and PO_2 should be repeated every one and one half or two hours until approaching normal. A chest x-ray, complete blood count, and throat culture should be done as soon as possible.

Sedation can be given if the patient is very hyperactive, anxious and irritable. This should be used with great caution because of possible respiratory depression. Chloral hydrate by rectum up to 50 mg/kg will not depress respirations.

Intravenous fluids are administered beginning with a rapid infusion of a plasma volume expanding solution and then enough fluid for maintenance and correction of deficits.

Acidosis is corrected by intravenous alkalinization. Sodium bicarbonate solution is given initially. If this is not effective in a very seriously affected patient with a very high pCO_2 (above 65mm. of mercury) and a pH less than 7.2, Tromethamine Tris (hydroxymethyl) Aminomethane, (THAM)* can be used, but only if the ventilation of the patient can be adequately controlled. The amount of base or alkalinizing solution to be used can be calculated by the following formula: BE (base excess) x body weight (kg) x 0.3 = meq. alkalinizing agent. However, many patients with acute respiratory distress may have a normal base excess. It is possible then to use the Kaplan formula: dosage (in meq.) alkalinizing agent = 1.5 x body weight (kg.) per hour. The solution should be infused slowly over a period of one-half to one hour. Additional alkalinizing agent is given depending on the subsequent determination of pH and pCO_2 and the clinical state of the patient regardless of base excess. Preparations of sodium bicarbonate contain 0.9mEq/ml in a 7.5% solution. Preparations of Tromethamine Tris (hydroxymethyl) Aminomethane contain 0.3mEq. per ml in a 0.3 M solution.

The rationale for correction of arterial pH in status asthmaticus is based on improvement in systemic and coronary circulation following intravenous alkalinization and the fact that acidosis has a deleterious effect on the pulmonary perfusion in a patient with bronchoconstrictive disease. There have been instances reported in adults where intravenous sodium bicarbonate has caused prompt return of the bronchomotor activity.[3] The administration of sodium bicarbonate will generate more CO_2 and may result in a transient rise in the pCO_2 of 4-8 mm. of mercury, which is probably insignificant and takes place while correcting the pH. This rise in pCO_2 does not occur with the use of Tromethamine Tris (hydroxymethyl) Aminomethane and may be a theoretical advantage. Yet, THAM has a disadvantage in that the clinical doses employed can produce respiratory depression. Very large doses of either Tromethamine Tris (hydroxymethyl) Aminomethane or sodium bicarbonate may cause hyperosmolality because of the high solute load. Alkalinization corrects metabolic acidosis but not respiratory acidosis. Respiratory acidosis is corrected by ventilation of alveoli.

Aminophylline should be given intravenously. This is a potent bronchodilator even in the presence of acidosis. It also acts as a mild respiratory stimulant and is mildly diuretic. The dose is normally 5 mg/kg/dose, but if a considerable amount of drug has been given in the previous 24 hours, the dose should be reduced to 3-4 mg/kg/dose. Aminophylline is added to about 50cc of hydrating solution, given over a period of 10-15 minutes, and can be repeated in eight hours as needed.

Corticosteroids are given intravenously. Hydrocortisone succinate (Solucortef) should be given (by push). It is best to give two to three times the stress dose of 200 mg/m^2 per 24 hours. Give one-half of the 24 hour dose first, then follow with one-fourth of a 24 hour dose every six

*THAM-E (Abbott)

hours. The dose of corticosteroids is tapered after 24-36 hours. If the patient has been receiving maintenance corticosteroids within the past six months, corticosteroids are definitely indicated. When the patient can tolerate oral medication, Prednisone is given. If corticosteroids are given for five days or less, the drug can be stopped abruptly, otherwise gradual reduction of the dose is best. One should not expect a dramatic effect from the administration of steroids, as it takes several hours before an anti-inflammatory effect takes place.

Antibiotics should be given intravenously. This is especially important if there is evidence of pulmonary complication such as pneumonitis, atelectasis, pneumothorax, pneumomediastinum, etc. A broad spectrum antibiotic such as Ampicillin is often used.

Sodium iodide may occasionally be used intravenously to decrease the viscosity of the bronchial secretions and enhance their removal. The dosage is 25 mg. per kilo added to 250cc of intravenous fluid and given over a period of four hours, not more than once a day. If there is question of sensitivity to iodides, this drug should not be used.

At times, in spite of the above measures, the patient gets worse and develops symptoms of impending respiratory failure or the patient may be seen for the first time in this advanced state. The following clinical signs will be noted: (1) severe inspiratory retractions with gasping, (2) minimal thoracic movement with hyperinflation, (3) on auscultation of the chest, wheezing and breath sounds are barely audible which indicate a very poor prognosis, (4) depressed level of consciousness and diminished response to painful stimuli, (5) cyanosis in 40-60% ambient oxygen, and (6) the pH may be below 7.2, the pCO_2 above 65 mm. of mercury, and the pO_2 below 40 mm. of mercury. If these conditions exist, one must immediately call the anesthesiologist because measures must be taken to increase alveolar ventilation by assisted ventilation.

Intermittent positive pressure breathing with a Bennett or other comparable mechanical respirator can be attempted with a mask. A possible disadvantage is that small children won't cooperate and may become more severely hypoxic from fighting the mask. One can also try assisted ventilation with a high flow of oxygen by bag and mask, but this technique has the same disadvantage as discussed above. Isoproterenol aerosol can be used with intermittent positive pressure breathing at this time and will be discussed in a subsequent paragraph. In conjunction with these procedures simultaneous gentle manual compression of the thorax during expiration decreases the volume of trapped gas in the lungs.

The above measures are often not effective and mechanical ventilation must be instituted after insertion of an orotracheal or nasotracheal tube. This procedure should be done by the anesthesiologist and the technique commonly used is as follows: The patient is sedated with intravenous sodium pentobarbital and bagged with O_2. A short acting muscle relaxant (Succinylcholine chloride) is given intravenously. This relaxes the muscles of the thorax and abdomen permitting easier inflation of the lungs. The endotracheal tube is inserted and connected to a pressure cycled or volume controlled mechanical ventilator. The pressure cycled device provides a flow into the lung until a preset cycling pressure is achieved causing the valves to close. These devices can be triggered by the patient or self-cycled. However, decreased lung compliance and increased airway resistance may limit the volume of gas delivered with these machines. On the other hand, since the volume controlled ventilators provide the needed breath at whatever pressure is necessary to deliver the volume of air regardless of lung compliance or airway resistance, they are preferred by many.[2] With any machine, the expiratory phase is prolonged so there is slightly increased respiratory resistance preventing bronchial collapse and this provides a passive expiration. Pressures as high as 50-60cm. of water have been used to affect ventilation. After respiration is controlled, a long acting muscle relaxant, Flaxedil® (Gallamine triethiodide) is given intravenously. This drug is then continued along with sedation as needed.

Aerosol therapy can be administered through the nebulizer on the ventilator. Sterile saline is nebulized most of the time. A sympathomimetic aerosol such as isoproterenol can be used. Care must be taken in its use. The advantage in using isoproterenol is that it induces better relaxation of bronchial smooth muscle than epinephrine. One disadvantage is that after giving isoproterenol or even epinephrine, arterial pO_2 fails to rise or

even falls.[2,4] Therefore, in the presence of existing hypoxia and acidosis which in itself decreases the integrity of cardiac muscle, there is increased hypoxia. Another disadvantage is that isoproterenol causes marked increase in heart rate. Because of these disadvantages cardiac arrhythmias are prone to occur that can cause a sudden drop in blood pressure resulting in congestive heart failure. There have been reports in the literature of sudden death when epinephrine was given soon after the administration of isoproterenol.[5,6] It should be noted that since alveolar ventilation is deficient, the effectiveness of aerosolized isoproterenol is greatly reduced.

There are certain precautions we recommend in the use of isoproterenol in children in status asthmaticus. Use no more than 0.25cc of 1/200 isoproterenol solution in 9.75cc of sterile normal saline and do not nebulize this more than every six hours as needed. Nebulize with adequate oxygen. Monitor blood pressure and pulse very frequently during administration. Be prepared to digitalize by intravenous route at the first sign of fall in blood pressure or cardiac arrhythmia and increase the rate of respirations to increase oxygen administration.

Further measures of importance are: (1) endotracheal suction by strict sterile technique, (2) manual ventilation by bag with a greater pressure than that being used, for five minutes out of 30 minutes to prevent atelectasis, and frequent auscultation of the chest should be performed, (4) monitor the vital signs, pH, pCO_2, pO_2 and serum electrolytes frequently, and (5) epinephrine can be tried again after about 18-24 hours.

The patient will usually improve by 20-30 hours and by then epinephrine is usually effective. Mechanical ventilation can be stopped with the endotracheal tube in place. If respirations continue spontaneously and unlabored with good air exchange by auscultation, the tube can be removed. Endotracheal tubes have been maintained for as long as one week with no ill effects. Corticosteroids are stopped abruptly or gradually tapered after several days.

One must remember that patients with status asthmaticus should be cared for in an intensive care unit. The anesthesiologist is a very important member of the team when the patient is intubated. The nursing staff, pediatrician and allergist complete the necessary team effort in the care of these patients.

Summary

Treat the acute attack of asthma early with small frequent doses of epinephrine, maintain hydration of the patient, give adequate calories, and avoid oversedation and antihistamines. These measures can prevent status asthmaticus.

Treatment of the child in status asthmaticus should be influenced by serial arterial pH and blood gas determinations. Sufficient oxygen should be administered to restore the pO_2 to a normal or near normal level and intravenous fluids should be given to correct ketonemia and dehydration. Intravenous buffer solutions such as sodium bicarbonate should be given to correct the arterial pH, and mechanical ventilation instituted when respiratory failure is impending.

Newborn Respiratory Distress*

A Roentgenological Approach

HUGH J. WILLIAMS, M.D.†

—Here we have a baby. It is composed of a bald head and a pair of lungs—
—Eugene Field (1850-1895) The Tribune Primer

OVER 40 DIFFERENT conditions can cause respiratory distress in the newborn infant. Clinically it is often difficult to pinpoint the exact nature of the disturbance responsible for the respiratory difficulty. Every experienced neonatologist and pediatrician has encountered infants admitted with "typical hyaline membrane disease" in whom the true cause of the respiratory distress later proved to be esophageal atresia, diaphragmatic hernia, or some other initially unsuspected condition. Definitive therapy is dependent upon a specific diagnosis and since this is often obtainable only radiographically it is essential to obtain technically good chest films without delay in every newborn infant with respiratory embarrassment. Utilizing modern high speed portable equipment, satisfactory frontal and lateral films can be readily obtained in the nursery with minimal disturbance to the infant. Any physician who has witnessed the eventual death of an infant "too ill for chest film" from a radiographically diagnosable and surgically correctible lesion such as Bochdalek hernia or tension pneumothorax will staunchly testify that the advantages of a properly performed chest examination far outweigh its risks. These conditions can be conveniently classified according to the appropriate mode of treatment into two broad categories, medical and surgical.

Causes of Newborn Respiratory Distress:

1. Medical
   1. Non-pulmonary with pulmonary manifestations.
   2. Primary pulmonary.
2. Surgical

Non-pulmonary Causes of Newborn Respiratory Distress

1. Central nervous system disease.
2. Mechanical factors.
3. Congenital heart disease.

Central Nervous System Disease

Congenital brain disorders, birth injury to the brain, intracranial hemorrhage or maternal oversedation may all result in respiratory distress secondary to diminished inspiratory efforts. In addition, a substantial percentage of infants dying from hyaline membrane disease demonstrate varying degrees of intracranial hemorrhage. This latter phenomenon is probably a manifestation of anoxia and it further burdens the overtaxed respiratory efforts of the afflicted infant. Since nearly every pulmonary condition capable of causing significant newborn respiratory distress is demonstrable radiographically, the presence of a normal chest roentgenogram in an infant with breathing difficulty should direct the physician's attention to an extrapulmonary origin. In many instances this proves to be the central nervous system.

Mechanical Factors

Alterations in the anatomical structures responsible for normal respiration may cause respiratory impairment. Respiratory distress may result from pharyngeal prolapse of the tongue in infants with significant micrognathia, such as encountered in the Pierre-Robin syndrome.‡ A large tongue, such as present in congenital hypothyroidism, may also occasionally cause airway obstruction. Alterations in the configuration of the thorax, as present in the thoracic asphyxiating syndrome of Jeune[2] or the Ellis-van Creveld syndrome£ may also cause respiratory distress in the newborn period. Hypoplasia of the thoracic cage and related musculature occurs in various congenital disorders, including the Trisomy 17-18 syndrome, and may limit thoracic expansion, thereby provoking respiratory embarrassment. Infantile polycystic kidneys may be so massive at birth that they cause compression of the lungs with resultant respiratory distress. Pulmonary hypoplasia and pneumothorax are often found in association with renal agenesis and may produce respiratory distress.

Congenital Heart Disease

There are several types of inoperable congenital heart diseases characterized by heart failure, respiratory distress, and death within the first few days of life. The most commonly encountered heart disorder responsible for this sequence of events is the hypoplastic left heart syndrome. Early and accurate diagnosis is essential in order to differentiate the operable from the inoperable types of cardiac disease.

Pulmonary Causes of Newborn Respiratory Distress

1. Atelectasis
2. Hyaline membrane disease
3. Aspiration syndrome
4. Transient respiratory distress of the newborn
5. Infectious pneumonitis
6. Pulmonary hemorrhage
7. Congenital pulmonary lymphangiectasia

Atelectasis

The full-term, healthy infant completely inflates his lungs with the first few breaths of life[3] and persistent fetal atelectasis is rare. Incomplete expansion of the lungs, however, may occur in infants who are permature or possess poor musculature. Diminished aeration may also be encountered in infants with central nervous system disease or those born of overly sedated mothers. If an infant with one of the preceding disorders survives the primary process responsible for incomplete pulmonary expansion, the abnormal pulmonary densities visible on the initial chest roentgenograms disappear within a few days. Massive pulmonary atelectasis secondary to intrinsic or extrinsic bronchial obstruction may occur in the neonate and be difficult to distinguish from pulmonary agenesis. If thoracic vertebral anomalies are present, however, the most likely cause or failure of aeration of an entire lung is pulmonary agenesis since these anomalies are commonly associated.

Hyaline Membrane Disease

The respiratory distress syndrome is a major cause of neonatal death and is commonly encountered in premature infants, Caesarian section infants, and infants born of diabetic mothers. There are approximately 300,000 premature infants born each year in the United States and about 15 percent die, producing a total of approximately 22,000 deaths annually from this disease. Hyaline membrane disease may also occur in full-term infants but the incidence is low (1:6000). The etiology of this disorder is uncertain, but a deficiency of surfactin, a decrease in serum fibrinolysin, and pulmonary hypoperfusion have all been cited as possible causes[4]. Diffuse alveolar atelectasis and the formation of cosinophilic hyaline membranes in the alveolar ducts and alveoli constitute the pathological hallmarks of hyaline membrane disease. These membranes are not specific for this disorder, and similar membranes have been reported in the alveoli of older patients suffering from noxious gas inhalation, viral pneumonitis, rheumatic pneumonitis, or prolonged exposure to high concentrations of oxygen.

Most infants with hyaline membrane disease develop respiratory distress shortly after birth and the impression of a symptom-free interval of hours following delivery is usually due to inadequate observation. It can be stated with certainty that any infant who has breathed normally in all respects for eight hours will not develop hyaline membrane disease. Radiologically, a chest film taken at three hours of age will often show a fine reticulotgranular pattern in the lungs, even though the clinical findings may be mild or absent. A chest roentgenogram taken at six hours of age is nearly always positive in this disease. As previously stressed, whenever the chest film of an

Fig. 1—The characteristic diffuse bilateral reticulogranular infiltrate and air bronchogram of hyaline membrane disease were present in this 24-hour-old premature infant with this disorder.

infant with significant respiratory distress is negative, another cause for the distress, such as a central nervous system disorder should be sought[5]. The characteristic roentgenological findings of hyaline membrane disease consist of uniform, minute, reticulotgranular densities throughout both lungs (Figure 1). The tiny punctate densities represent atelectatic alveoli and contrast sharply with the air-distended brochial tree, producing the characteristic air bronchogram. In general, the more severe the roentgenologic findings in this disease, the poorer is the prognosis, particularly if the radiographic picture is progressive. Pneumothorax and pneumomediastinum are common complications and may necessitate surgical intervention. Intensive treatment, including the use of mechanical respirators, has improved the prognosis in this disease, but some of the survivors develop a therapeutic complication known as the respirator lung syndrome. Long-term studies to elucidate the eventual status of infants who develop this chronic complication are in progress.

Aspiration Syndrome

In the presence of fetal hypoxia, vagal stimulation occurs with resultant expulsion of meconium into the amniotic fluid. Aspiration by the fetus of this meconium-containing amniotic fluid produces an irregular type of mechanical obstruction in the smaller bronchi and numerous segmental areas of atelectasis. In addition to its mechanical effects, the aspirated meconium may provoke a severe chemical type of pneumonitis. Affected infants are usually postmature and demonstrate respiratory distress at the time of delivery or shortly thereafter. The roentgenologic findings are similar to those found in interstitial pneumonitis and are readily differentiated from the fine reticular pattern of hyaline membrane disease (Figure 2). There are coarse infiltrates in both lungs with associated air-trapping and diaphragmatic depression. Approximately 20 percent of affected infants die, with most deaths occurring in the first 24 hours of life. Treatment is supportive and consists of pulmonary lavage, aspiration of the stomach to remove swallowed meconium, administration of oxygen and employment of other necessary measures.

Transient Respiratory Distress of the Newborn

In most healthy infants the fluid which fills the alveoli during fetal life disappears into the pulmonary circulation with the first few breaths of life. The exact mechanism of this fluid transport into the pulmonary circulation is uncertain, but its rapid resorption is probably chiefly through the lymphatic channels and to a lesser degree of capillaries. In some infants there is delayed disappearance of this fluid, producing varying degrees of tachypnea and respiratory distress ("wet lung" disease) usually commencing within a few hours after birth[7]. Roentgenologically the lungs appear edematous and there are radiating linear streaks extending peripherally from each hilus. The presence of lung over-expansion and the fluid in the fissures aid in differentiating this condition from hyaline membrane disease, but positive radiologic differentiation is sometimes difficult on the initial chest film. Both the clinical and radiographic findings usually disappear within the first three days of life.

Infection Pneumonitis

Intrauterine pneumonitis may result from prolonged labor, premature rupture of the membranes, or hematogenous spread from an infected placenta[8]. In addition, certain viruses including rubella and cytomegalic inclusion, can pass the placental barrier and infect the fetus. Affected infants are

Fig. 2—A course infiltrate was present in the right lung of this full-term infant with meconium aspiration syndrome secondary to fetal hypoxia. The umbilical cord was twisted around the neck twice. Note the hyperaeration of both lungs due to obstruction of the smaller bronchi by meconium plugs.

usually quite ill at birth or shortly thereafter, and exhibit severe respiratory distress. Fever and leucocytosis are often absent, particularly in premature infants. The radiologic findings are those of an interstitial pneumonitis and are very similar to those of the aspiration syndrome. Clinical history, therefore, is essential in differentiating between those two conditions.

Pulmonary Hemorrhage

Pulmonary hemorrhage may occur as an isolated entity, or in association with hyaline membrane disease, the aspiration syndrome or other conditions[9]. The extravasation of red cells into the alveoli results from capillary damage by anoxia. Intrapulmonary hemorrhage is characterized clinically by the expectoration of bloody, frothy sputum. The radiographic findings are not diagnostic and consist of numerous non-specific areas of consolidation, the extent dependent upon the amount of hemorrhage. The outcome varies with the severity of the hemorrhage and the presence or absence of associated pulmonary disease.

Congenital Pulmonary Lymphangiectasia

This rare condition affects chiefly full-term infants and results from a failure of linkage of the pulmonary lymphatic spaces during fetal life[10]. Respiratory distress and cyanosis are usually present at birth and death nearly always occurs within a few hours or days. The diffuse pulmonary infiltrate somewhat resembles that of hyaline membrane, disease or anomalous infradiaphragmatic pulmonary venous return but tends to be coarser.

Surgically Correctible Causes of Newborn Respiratory Distress

1. Bilateral choanal atresia
2. Extrinsic airway narrowing
3. Intrinsic airway narrowing
4. Cardiovascular abnormalities
5. Diaphragmatic disease
6. Pneumomediastinum and pneumothorax
7. Congenital lobar emphysema
8. Cystic adenomatoid malformation
9. Aspiration pneumonitis

Bilateral Choanal Atresia

The newborn infant instinctively breathes only through the nose; oropharyngeal breathing is an acquired function which normally takes several weeks to learn. Because the newborn infant is an obligate nasal breather, bilateral choanal atresia usually causes severe respiratory distress at birth or shortly thereafter. The diagnosis is established by an inability to pass a rubber catheter through each nostril. Failure to consider and diagnose this condition is responsible for an indeterminate number of tragic newborn deaths annually from asphyxia[11]. Immediate establishment of an artificial airway is lifesaving. Elective transpalatal reaction of the obstructing septa (Figure 3) is performed later.

Extrinsic Airway Narrowing

Immediate respiratory distress may result during the newborn period from extrinsic compression of the cervical trachea by neck masses such as teratoma[12], goiter, or cystic hygroma (Figure 4). Mediastinal masses such as cystic hygroma, teratoma or duplication cyst may also provoke varying degrees of respiratory embarrassment by impinging on the intrathoracic airway or the venous return to the heart.

Intrinsic Airway Narrowing

Intrinsic narrowing of the airway may result from retrodisplacement of the tongue (Pierre-Robin syndrome), nasopharyngeal masses, or sub-

Fig. 3—Bilateral choanal atresia was demonstrable roentgenologically in this newborn infant with severe respiratory distress by a failure of the opaque medium instilled into both the right nostril (upper) and the left nostril (lower) to enter the pharynx.

glottic tumors such as hemangioma. Early recognition and surgical removal of a lesion producing significant extrinsic or intrinsic airway constriction are essential to prevent death from asphyxia.

Cardiovascular Abnormalities

Numerous congenital malformations of the heart and great vessels can cause respiratory distress in the newborn period. An enlarged cardiac chamber or pulmonary artery in acyanotic congenital heart disease may compress a major bronchus producing obstructive emphysema or atelectasis[13]. A vascular ring encircling the esophagus and trachea frequently narrows these structures sufficiently to produce choking and respiratory distress, particularly during feedings[14]. Similarly, a vascular sling (ectopic left pulmonary artery) may cause respiratory embarrassment through compression of the trachea or the right main bronchus[15]. A barium esophagogram will usually detect either of these conditions and can be simply performed with little risk to the infant (Figure 5). Total anomalous infradiaphragmatic pulmonary venous return is characterized roentgenologically by a reticuloganular pattern of the lungs sec-

Fig. 5—The arrows indicate the sites of compression of the trachea anteriorly and the barium-filled esophagus posteriorly in this infant with a vascular ring (double aortic arch). The respiratory symptoms were relieved following surgical division of the ring.

Fig. 4—Severe anterior compression of the trachea with marked respiratory distress was present in this newborn infant due to a large, benign cervical teratoma. The respiratory embarrassment was immediately relieved by surgical excision of the tumor.

Fig. 6—A large left-sided Bochdalek hernia was responsible for progressive respiratory distress in this 12-hour-old infant. Note the gas containing viscera in the left hemithorax and the marked mediastinal shift to the right. The hernia was successfully repaired surgically.

ondary to pulmonary venous congestion and a normal-sized heart[16]. The reticulogranular pattern of the lungs in this condition is similar to that encountered in hyaline membrane disease but tends to be coarser. Early diagnosis of the preceding cardiovascular abnormalities is important since surgical correction of the underlying cause is often possible with subsequent relief of the respiratory distress.

Diaphragmatic Disease

Developmental defects in the diaphragm may permit intrathoracic herniation of both the solid and hollow abdominal viscera during fetal life. Progressive respiratory distress frequently develops in such infants during the first few hours of life. The most frequent site of diaphragmatic herniation is posterolaterally through the foramen of Bochdalek, more commonly on the left[17]. Progressive gaseous distention of the herniated hollow viscera develops after birth, resulting in an escalating type of respiratory distress (Figure 6). Early diagnosis and corrective surgery of diaphragmatic hernias are mandatory. The diagnosis is often apparent clinically, particularly when bowel sounds are heard in the chest, but every experienced pediatrician and roentgenologist can recall instances where the initial clinical diagnosis of "hyaline membrane disease" was quickly amended to Bochdalek hernia following an admitting chest film. With modern roentgenologic techniques, there is little excuse for failure to establish an early diagnosis of diaphragmatic hernia in a newborn infant with respiratory distress on this basis. Foramen of Morgagni hernia and esophageal hiatal hernia occur less commonly and are seldom life-threatening. Eventration of the diaphragm, particularly when associated with other pulmonary disease, causes respiratory distress during the neonatal period and requires surgical correction.

Pneumomediastinum and Pneumothorax

Pneumomediastinum is usually secondary to alveolar rupture from increased intra-alveolar tension[18]. The antecedent alveolar hypertension may be primary from the increased respiratory efforts of a pulmonary disorder such as hyaline membrane disease, or may be secondary to the overenergetic use of mouth to-mouth resuscitation or positive-pressure apparatus. In infants, the mediastinal air progressively accumulates within the mediastinum, and seldom decompresses into the cervical soft tissues, as it does in older children and adults. If the pressure of the accumulated mediastinal air becomes excessive, impairment of the venous return to the heart may result. In some cases of pneumomediastinum rupture of the pleura with resultant pneumothorax may occur. Pneumothorax should always be suspected in any infant with mild-to-moderate respiratory distress whose symptoms suddenly become worse. Such a change should always prompt an immediate chest film (Figure 7), since an unrecognized and untreated tension pneumothorax may cause rapid deterioration and death. Needle aspiration of any significant pneumothorax or pneumomediastinum, followed by insertion of a suction, is easy to perform and is life-saving.

Fig. 7—The respiratory distress in this infant with hyaline membrane disease became suddenly worse. An immediate chest film revealed development of an acute right tension pneumothorax. The severe distress was relieved following insertion of a pleural tube and institution of suction.

Congenital Lobar Emphysema

This uncommon cause of respiratory distress, tends to involve the upper lobes and the right middle lobe. It seldom causes respiratory distress in the first few days of life but occasionally it may pursue a fulminating course characterized clinically by dyspnea and cyanosis during this period[19]. The emphysematous lobe produces com-

pression atelectasis of the uninvolved lung, depression of the ipsilateral diaphragm, and displacement of the mediastinum to the opposite side (Figure 8). Immediate surgical resection of the involved lobe is life-saving.

Cystic Adenomatoid Malformation

This rare congenital anomaly represents a hamartomatous cystic overgrowth of the normal lung respiratory elements[20]. In most instances the pathologically involved lung does not cause symptoms in the first few days of life, but sometimes respiratory distress begins during this period. This entity usually involves only one lobe, but occasionally an entire lung or both lungs may be affected. Radiologically an intrapulmonary cystic mass is demonstrable, and frequently the enlarged lobe herniates towards the opposite side. In a few instances cystic adenomatoid malformation has been mistaken for diaphragmatic hernia, owing to the resemblance of the cystic structures to intrathoracic bowel. This error can be prevented by noting that the gas-containing abdominal viscera are normally located within the abdomen in cystic adenomatoid malformation. Treatment consists of surgical resection of the affected lobe.

Gastrointestinal Tract Abnormalities

Severe anatomical abnormalities of the gastrointestinal tract often result in esophageal overfilling and tracheal aspiration with secondary pneumonitis: a sequence of events usually due to an obstructive lesion, such as esophageal atresia

Fig. 8—Lobar emphysema of the left-upper lobe was responsible for increasing respiratory difficulty in this infant. Note the compression atelectasis of the left-lower obe and the mediastinal shift to the right caused by the markedly hyperinflated left-upper lobe.

Fig. 9—Both right-upper lobe atelectasis and aspiration pneumonitis were present in this 12-hour-old infant with esophageal atresia and tracheoesophageal fistula. The admitting diagnosis was hyaline membrane disease and it was this roentgenogram which led to establishment of the correct diagnosis.

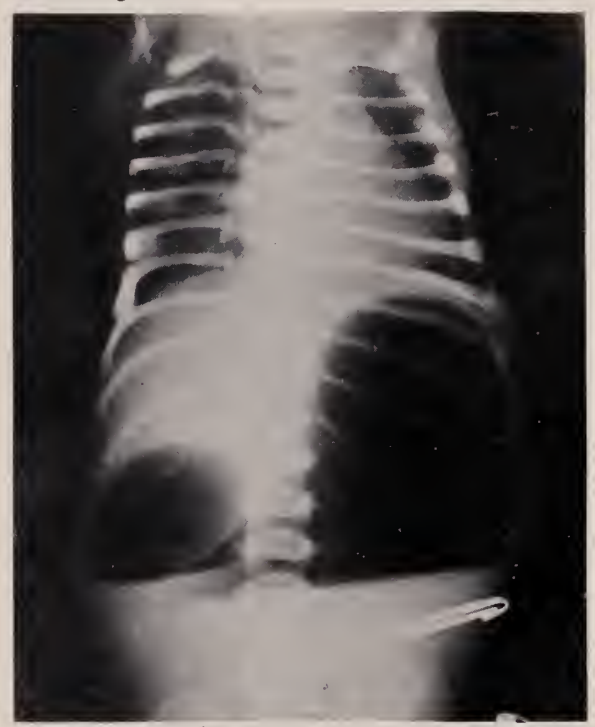

Fig. 9—Both right-upper lobe atelectasis and aspiration the right lung of this newborn infant. Note the "double bubble" configuration of the gas and fluid with the stomach and duodenum. This radiographic feature associated with a complete absence of small bowel gas is characteristic of duodenal atresia (present in this patient) or annular pancreas.

(1:5000 births). Right-upper lobe pneumonitis nearly always develops within 24 hours after birth in infants with esophageal atresia, unless preventive measures are taken (Figure 9). Aspiration pneumonitis in the newborn period may also result from duodenal atresia, annular pancreas, or small bowl obstruction from various causes. In addition, pharyngo-esophageal incoordination, chalasia and esophageal hiatal hernia may also produce aspiration pneumonitis. Less frequently, aspiration pneumonitis may result from an abnormal communication such as laryngotracheoesophageal cleft[21], biliary-bronchial fistula or jejuno-bronchial fistula.

Summary

A wide spectrum of medical and surgical disorders capable of producing respiratory distress in the newborn period has been presented. It is emphasized that the clinical signs and symptoms are similar in many of these conditions and that a definitive diagnosis can frequently be established only by a chest roentgenogram. This examination is the single most valuable diagnostic measure available in determining the cause of newborn respiratory distress. It is unjustifiable to delay radiographic examination of the newborn infant with severe respiratory distress on the assumption that he is "too sick to be x rayed." With modern equipment this valuable procedure can be performed with minimal disturbance and risk to the infant. A plea is made for the early, careful roentgenological examination of any newborn infant with respiratory distress; the potential rewards of this examination far outweigh any risk.

Ellis-van Creveld Syndrome*

This syndrome is characterized by chondrodysplasia, ectodermal dysplasia, polydactyly, and congenital heart disease. It is considered to be a recessive, inherited defect without sex linkage. The proximal segments of the limbs tend to be more reduced in length than the distal portions. There may be super-numerary digits. There is usually no mental abnoramility associated.

Fractures of the Tibial Spine in Children

Open or Closed Treatment?

IVAN SCHLOFF, M.D. AND RONALD M. LAMPERT, M.D.

FRACTURES OF THE TIBIAL spine are predominantly injuries of youth, although they may occur at any age. This injury may occur independent of other injuries and is generally considered to be due to a direct blow to the anterior aspect of the flexed knee which drives the femur backwards on the fixed tibia. A rapid hemarthrosis develops, which when aspirated often contains fat droplets. It is felt that because of the relative resilient nature of the anterior cruciate ligament, trauma results in fracture of the tibial spine rather than rupture of this ligament. In a young child, hyperextension of the knee alone may be sufficient to avulse the attachment of the anterior cruciate ligament. Adults with findings of internal derangement of the knee, including abnormal anteroposterior mobility due to a ruptured or attenuated anterior cruciate ligament, sometimes demonstrate radiographically an old, unreduced fracture of the tibial spine sustained during childhood. In the very young child, the symptoms are similar to those of a torn semilunar cartilage with locking and inability to fully extend the knee. Avulsion of the anterior cruciate ligament usually occurs in children between six and twelve years of age while osteochondral fracture of the articular surface is usually encountered at a later age. In a series reported by McLaughlin of 42 such injuries 21 patients were under seventeen years of age and 21 patients were over this age.[1]

At times, the patient does not visit the doctor for several days and by this time the knee is often quite swollen. Passive extension is absent on physical examination and roentgenograms demonstrate a small flake of bone avulsed from the tibia.

Prompt recognition of this injury is of great importance. The ideal, early treatment is replacement of the displaced fragment. Closed methods are occasionally successful and should always be attempted. More often, however, the fragment must be fixed by open reduction. The best results with the closed method are obtained in children, and adults often require open reduction. Closed reduction is most successful when the cartilage is intact posteriorly and the surface area of the fragment extends under the femoral condyle so as to be compressed in extension. If conservative therapy is elected, the patient is given a general anesthetic, the knee first being aspirated in order to obtain full extension. A long leg plaster cast is then applied and immobilization carried out for a period of six to eight weeks. When the fracture is neglected for several weeks, conservative treat-

Fig. 1A—The avulsed tibial spine fragment (arrow) is visible in the anteroposterior film of this twelve-year-old boy (Case 1).

Fig. 1C—The avulsed tibial spine has been surgically replaced and fixed in normal position by a wire.

Fig. 2A—The avulsed tibial spine (arrow) is located in the intercondylar region of the femur in this ten-year-old girl who fell from her bicycle.

Fig 2B—The post-operative roentgenogram demonstrates wire fixation of the tibial spine in normal position.

ment is indicated if the fragment is not grossly displaced. This consists of a long leg plaster cast applied with the knee in ten degrees of flexion for a period of three to four weeks. Results, according to Blount are good.[2] Surgery is indicated whenever closed reduction fails, the fragment causes a bony block to full extension, or when the fragment is so small it cannot be reduced by manipulation. When this occurs, there is a relative lengthening of the ligament which will not permit normal function of the knee. Open reduction consists of opening the joint and replacement of the bony fragment in its bed. Using two drill holes, the fragment is fixed by inserting wires through the holes and attaching them to the tibia just proximal to the tibial tuberosity. Care must be taken not to damage the epiphyseal cartilage which is located distal and posterior to the drill holes.

Case Reports

Case 1

This 12-year-old boy was admitted to St. Paul Childrens Hospital following an injury incurred while jumping hurdles. He missed a hurdle, striking the front of his left leg. Figures 1A and 1B show an avulsion fracture of the anterior tibial spine (arrow) along with a portion of the tibial plateau. The avulsed fragment has been displaced into the intercondylar notch. Under general anesthetic the knee was aspirated and an unsuccessful attempt at closed reduction was made. The knee was then opened and closed reduction performed successfully. Reduction of the fracture fragment and internal fixation by a wire loop is demonstrated in the post-operative roentgenogram (Figure 1C). A posterior molded plaster splint was applied for six weeks.

Case 2

This ten-year-old girl was seen at Childrens Hospital following a fall from a bicycle. She struck her upper tibia on the curb, forcing the tibia backward on the femur. X rays demonstrated an avulsion of the anterior tibial spine (arrow) with displacement of this structure into the intercondylar notch. (Figure 2A) Under general anesthetic, a closed reduction was attempted, but this was unsuccessful. The knee therefore was opened and reduced as shown in Figure 2B.

Both of these patients went on to full recovery. Subsequent examinations demonstrated a full range of motion in the involved knee and stability of the cruciate ligaments.

Summary

Fractures of the tibial spine in children can result from either a direct blow to the anterior aspect of the flexed knee or from hyperextension of the knee. Closed reduction should always be attempted initially in an effort to obtain anatomical reduction. If this proves unsuccessful, open reduction should be performed in order to prevent a lengthening of the anterior cruciate ligament with resultant malfunction of the knee.

Pierre-Robin Syndrome

The many features of the Pierre-Robin syndrome include hypoplasia of the mandible, cleft palate, retraction or prolapse of the abnormally small tongue. These cause dyspnea, cyanosis and difficulty in swallowing, aggravated when the infant lies on his back or during feeding. There is a tendency to infection, poor nutrition, and often final cachexia.

With proper treatment the abnormality improves spontaneously at the age of one month. Syphilis, alcoholic excess in either parent, avitaminosis B_2 have been considered as possible etiologic factors.

Pancytopenia Following Hepatitis

RAJ DUTT, M.D.* AND KRISHNA M. SAXENA, M.D.*

APLASTIC ANEMIA with or without associated pancytopenia is rather uncommon in childhood. A bone marrow aplasia can be produced by a variety of causes including genetic disorders, radiation, drugs and chemicals, infections and malignancy. In recent years the association of aplastic anemia with hepatitis has been observed in a number of cases.[1] The following report deals with a child in whom pancytopenia developed during an attack of infectious hepatitis.

Case Report

A three-year-old white female child was admitted to The Childrens Hospital, St. Paul, with generalized purpura, hepatosplenomegaly and scleral icterus.

The child had been in excellent health until about two weeks before admisison when the mother first noticed some "red spots" on both legs. The child had no fever or abdominal pain; she was eating well and was active. However, she had felt more tired for about two weeks before admission. There was no history of ingestion of any toxic substance and no exposure to any infectious disease, including infectious hepatitis.

Physical Findings

The physical examination revealed a cooperative three-year-old with a temperature of 99.4°, pulse 100/min., respirations 22/min. and blood pressure of 90/50 mm. Hg. Her weight was 35 lb. and her height was 39½", putting her in the 50th percentile for age. She had multiple petechae and areas of ecchymosis all over her body including the buccal mucosa. There was a sub-conjunctival hemorrhage in the left eye. Her sclerae were icteric but the skin was not jaundiced. The anterior and posterior cervical glands were enlarged bilaterally; non-tender, firm and freely movable. The liver was firm, non-tender and enlarged to 8 cm. below the costal margin. The spleen tip was palpable. The systemic examination was otherwise negative; the central nervous system was unremarkable.

Laboratory Studies

The initial laboratory findings were as follows: Hb 8.9 Gm%, hematocrit 26%, total WBC 3,800/ccm, reticulocyte count 2.1%, serum bilirubin 4.7 mg% (direct 3.3 mg%), alkaline phosphatase 52.3 KA unit, SGOT 1750 units and LDH—200 units with significant increase in fraction 5 suggesting liver damage. The blood was negative for Australian antigen. Platelet count was 20,000/cmm., PTT—75.4 seconds with a control of 83.3 seconds and prothrombin time 11.9 seconds with control of 11.8 seconds.

Results of some of the other tests done over the next few days were as follows: Coombs'—negative, L.E. test neg., FANA neg., infectious mononucleosis screening test neg., Haptoglobins 128 mg%, serum iron 303 mcg%, iron-binding capacity 613 mcg%, Ceruloplasmin normal, serum Folate 7 $\mu\mu$g/ml. Vit. B_{12} 590 $\mu\mu$g/ml; immunoglobulins: IgG 980 mg%, IgA 128 mg% & IgM 180 mg%. Radiographs of the long bones and chest were negative, I.V.P. was negative.

The peripheral blood film showed a severe anemia, leukopenia and thrombocytopenia. The red cells revealed hypochromia and anisocytosis, poikilocytosis, occasional target forms and slight polychromasia. Platelets were almost non-existent.

Bone Marrow

The bone marrow showed hypoplasia of all elements and fatty infiltration. There was almost complete absence of megakaryocytes and RBC precursors. There were only 2% normoblasts. The number of lymphocytes, histiocytes and macrophages was increased. Neutrophils and precursors were markedly decreased in number. Eosinophils and precursors were scarce (Figure 1).

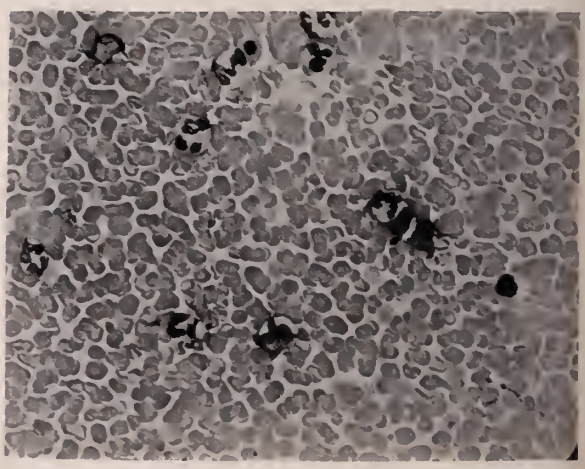

Fig. 1—Bone marrow. Note the marked hypocellularity of precursor cells.

Liver Biopsy

A liver biopsy was performed on the eighth day of admission after a platelet transfusion. The biopsy showed disorganization of the lobular structure of the liver. The parenchymal cells were swollen and pale with a ground-glass or granular appearance and micro-vacuolization. There was some mononuclear cell infiltration around the portal spaces. It was, thus, consistent with the diagnosis of infectious hepatitis (Figure 2).

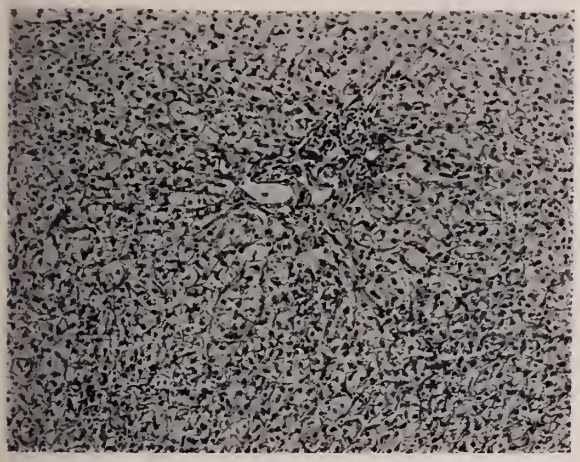

Fig. 2—Liver biopsy showing periportal mononuclear infiltration and swelling of the parenchymal cells.

Diagnosis

A diagnosis of pancytopenia associated with hepatitis was made.

Progress

She was started on Prednisone 40 mg. daily. On the fourth day of admission, she developed hematuria and blood-stained sputum. The Hb was 7.8 gm/%, total WBC 3850/cmm, the platelets 21,000/cmm. She was transfused with platelets, after which platelet count increased to 108,000. Two days later, the platelet count was again down to 42,000. The RBC, platelet and WBC changes are depicted in Figure 3 and the temperature chart and therapy in Figure 4.

On the 16th day of admission, the Hb was 5.6 gm% and the platelet count 11,000. The liver function tests done at this time showed significant improvement. On the 25th day of admission, she developed a temperature

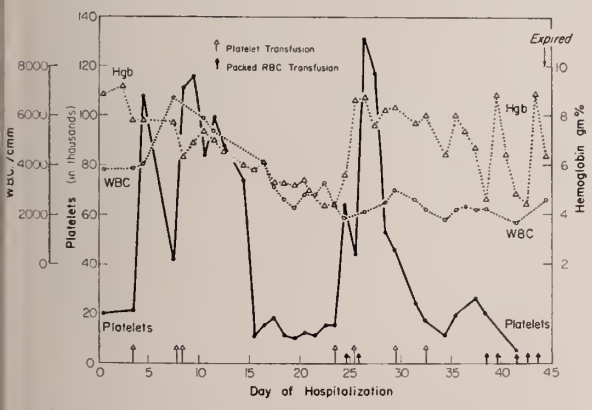

Fig. 3—Peripheral blood count and transfusions during hospitalization.

of 103°F. Blood cultures were obtained and she was treated with Ampicillin, 200 mg/kg/d and Methicillin 200 mg/kg/d for one week. The cultures were negative.

During the next few days, her condition remained unchanged. She continued to have episodes of bleeding from the gums, melena and hematuria. She was given multiple platelet transfusions to control bleeding, but it was soon evident that the platelets were being destroyed almost immediately after the transfusions (Figure 3) which were, therefore, discontinued.

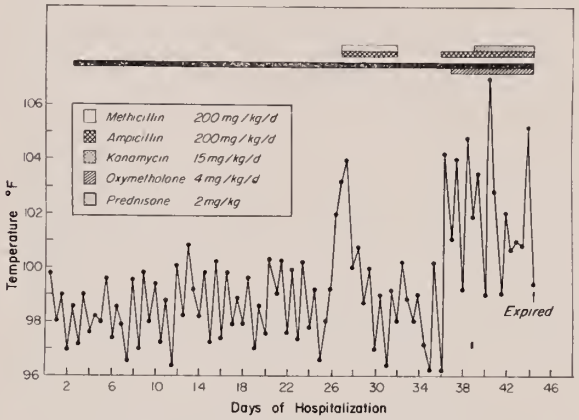

Fig. 4—Hospital course and therapy.

Her general condition gradually worsened. She became very irritable and lethargic and developed side effects of steroid therapy. Her hemoglobin continued to drop and she was transfused with packed cells with moderate increase in hemoglobin.

On the 36th day, her temperature spiked again and after cultures were obtained, she was started on Ampicillin 200 mg/kg/d intravenously but spikes of temperature ranging between 100-105°F. continued. The initial urine, blood and throat cultures were negative. However, three days later a blood culture grew E. Aerogenes resistant to Ampicillin but sensitive to Kanamycin which was started in a dose of 15 mg/kg/day. Her general condition continued to be poor although she was still alert. She developed large areas of ecchymosis all over her body and fresh blood in her stools.

The liver functions had returned to normal by this time and, since her anemia was not responding to Prednisone, it was decided to treat her with androgens. Oxymetholone was started in a dose of 5 mg/kg orally on the 37th day after admission.

On January 21, the 45th day of admission, she developed convulsions and became comatose. The cerebrospinal fluid was cloudy and smear showed gram-negative rods. The culture was positive for Klebsiella pneumoniae. She continued to have convulsions, developed shock with marked ecchymoses and melena and expired the same day. Unfortunately, permission for autopsy was refused by the parents.

Discussion

The association of viral hepatitis and bone-marrow aplasia is undoubtedly rare[1-15] and only 33 case reports have been published, to our

knowledge, in the world literature since the first report by Lorenz and Quaisar in 1955.[2] The occurrence of transient hemolytic anemia and mild transient leukopenia and thrombocytopenia with viral hepatitis is well known.[16-17] However, the patients with aplastic anemia discussed here fall in a different category. The clinical picture and autopsy findings in the reported cases are consistent enough to establish "aplastic pancytopenia following hepatitis" as a separate and definite clinical entity. The rapidly progressive course and high mortality rate of 80% make it noteworthy despite its rarity.

Initial Illness

Clinical and histological data strongly suggests that the liver disorder in these patients was infectious hepatitis. Over two-thirds of the cases were males and 50% were under the age of 16 years. The illness and initial course usually began like classical infectious hepatitis. However, in most cases, one to 10 weeks following onset of hepatitis, there was development of pancytopenia. Often the liver disorder was improving at the time bone marrow aplasia manifested itself clinically.

Our patient followed the usual pattern of presentation except that the hepatitis was mild and first became evident when the child came to the hospital for extensive ecchymosis.

Cause of Death

In 22 of the 28 cases about which we have detailed information death occurred either as a direct result of anemia and bleeding or due to sepsis secondary to neutropenia.

The survival time from onset of hepatitis ranged from three to 51 weeks with an average of about 10 weeks. On autopsy, most patients showed hepatitis in various stages of healing with evidence of massive necrosis in a few cases. The bone marrow showed hypoplasia or aplasia involving all cellular elements and replacement by fat. Evidence of bleeding and/or sepsis was present in almost all patients.

The liver condition of our patient improved but the marrow aplasia continued and she died of massive hemorrhage and sepsis. Autopsy was not permitted but the liver biopsy and two bone marrow biopsies during life left little doubt about the diagnosis.

Etiology

A number of hypotheses about the etiology of marrow aplasia have been discussed (Table).

TABLE
Etiological Factors

1. **Toxin**
2. **Auto-immune process**
3. **Virus infection:**
   Marrow depression
   Chromosomal damage
4. **Failure of liver to detoxify myelosuppressive agents**

There is no evidence that a toxin whether exogenous or endogenous is involved in the causation of marrow depression. An autoimmune theory has been suggested but not proven.[9] At the present time, it seems most likely that the virus infection itself is responsible for damaging the bone marrow. Rubella,[18] dengue fever,[19] and mumps[20] are known to produce transient bone marrow depression; marrow aplasia in cats by the virus of malignant leukopenia has been demonstrated;[12] and the MHV-3 virus[22] as well as the equine encephalitis virus[23] have produced degenerative changes in hemopoietic elements and pancytopenia in mice. Furthermore, transient mild anemia, leukopenia and thrombocytopenia occur in many patients with infectious hepatitis.[17] Thus it is not incomprehensible that during the stage of viremia more severe damage to the hemopoietic system may result in later aplasia in some patients. Another interesting possibility raised by Rubin and colleagues[1] is that the virus may cause marrow depression not by direct damage but by inducing chromosomal changes in the hemopoietic tissue. In any case, the association of hepatitis and marrow aplasia is too definite to be considered just a coincidence.

Therapy

The therapy of aplastic anemia and the support of the patient until the treatment becomes effective merit some comment. The action of androgens is slow and it may take several months before the effects are visible.[24] In our case, the institution of androgen therapy was delayed because of the presence of hepatic dysfunction. Hepatic damage has been observed during therapy with androgens.[25] In retrospect, we feel it might have been justifiable to start androgen therapy earlier.

The difficulty in maintaining respectable levels of circulating platelets by repeated *platelet transfusions* from random donors is obvious. We had no facilities for platelet matching; however, if platelets from family donors matched for histocompatibility can be given, it is possible to produce excellent clinical response for prolonged

periods of time.[26]

Another form of therapy which to our knowledge has not been tried in this group of patients but may have potential, is hepatitis *immune globulin*. It might prevent damage to the hemopoietic tissue by interfering with the virus. Whether it proves successful is still to be seen.

Summary

We have presented the case of a three-year-old girl who developed jaundice and hepatosplenomegaly with simultaneous purpura and ecchymoses. Liver biopsy was consistent with viral hepatitis. She developed a severe persistent pancytopenia and ultimately expired due to hemorrhage and sepsis seven weeks after the onset of the first symptoms. The entity of aplastic pancytopenia following hepatitis seems to be well defined and carries a very high mortality.

Lead Poisoning in Children

The U.S. Public Health Service recommends that screening programs for the detection, treatment, and prevention of lead poisoning in children include all those children who are one to six years of age and living in old, poorly maintained houses. Lead-based paint was commonly used for home interiors as well as for exteriors until the 1940s. It has been largely replaced by titanium-based paint. Minneapolis and St. Paul have within recent years passed ordinances specifically prohibiting the use of paint containing more than 1% of lead. Cribs and other household furniture may also have been painted and repainted with lead-based paint. The lead problem is particularly important and widespread in the slums of the cities, but may also be found in old homes throughout the state.

Children exposed to other special conditions involving lead hazards should also be screened. Recent reports indicate that pencil-chewing children may be exposed to a health hazard if a large part of the painted area of the pencil is chipped of, such as a third or more of the total surface. The paint in some pencils has been reported as high as 12% lead whereas a maximum of 1% is generally regarded as safe.

Dr. Jesse L. Steinfeld, Surgeon General of the Public Health Service, has urged that more cities establish programs to locate and treat children suffering from lead-based paint poisoning and to remove the sources of lead from their homes to prevent re-poisoning. Lead-screening studies have found elevated lead levels in 5-10% of the children tested.

The Surgeon General's statement says that a concentration of 40 micrograms or more per milliliter should be considered evidence of undue absorption of lead. The current degree of exposure to lead paint in children with such blood lead values should be determined. If local resources do not permit immediate evaluation of all such children, priority should be given to those with lead values of 50 micrograms or more.

Among children who have blood lead values of 40 to 49 micrograms, those who are one to three years old should be given top priority. This age group comprises approximately 85% of the reported cases of lead poisoning and has the highest mortality rate from the disease.

Children with levels of 80 micrograms or more should be considered unequivocal cases of lead poisoning and regarded as medical emergencies. They should be hospitalized immediately and given chelation therapy, and the source of poisoning should be promptly removed to prevent re-poisoning. The statement points out that the risk of acute lead encephalopathy in this group is great, and if this brain disorder develops at least 40% of the affected children will sustain severe and permanent brain damage. Mental retardation and, in some cases, even death can result.

Until such time as funds become available for large scale screening and childhood lead control programs, the Minnesota Department of Health will assist localized areas of "high-risk" in developing and financing limited screening and control programs. Laboratory services for blood lead analysis have been and continue to be available from the Section of Analytical Services of the State Health Department. Copies of all reports of abnormal lead levels, 40 micrograms or more, are referred to the Section of Maternal and Child Health for follow-up as to medical care as well as to the source of poisoning and its elimination.

Spontaneous Scrotal Rupture

From an Incarcerated Inguinal Hernia

B. G. LANNIN, M.D.*

INGUINAL HERNIA is the most commonly encountered condition requiring abdominal surgery in a pediatric hospital. The performance of inguinal herniorrhaphy is exceeded in frequency only by tonsillectomy. The actual incidence of inguinal hernia in the childhood population has been estimated to be between .8 per cent and 4.4 per cent. It may be even higher in premature infants.

The largest number are observed during the first year and, in further considering those occurring during the first year, the greatest numbers are seen during the first month, with 80 per cent having been noted by the third month. Incarceration may occur fairly commonly, but actual strangulation requiring emergency surgery[1] is rather unusual. The following case report details a complication of incarcerated inguinal hernia which has not been noted in a brief survey of the literature and pediatric surgery in text books.

Case History

This full-term male infant was born of an uncomplicated delivery and seemed to progress quite normally after birth. At two weeks of age, a "lump" in the groin was noted by the family and the baby was taken to the family physician who diagnosed a scrotal hernia. Surgery was scheduled for "after the holidays." However, the lump in the scrotum continued to increase in size until it was approximately the "size of a lemon," the hernia could always be easily reduced without any discomfort. The week prior to admission, however, it was noted that the scrotum was "purplish blue." At 5:30 A.M. on January 2, 1967, during a feeding, the child appeared to stiffen up and cry and the father noted a slit in the skin of the scrotum. A short time later bowel was noted to protrude from this defect, and the child was immediately taken to the hospital where he was examined by his family physician and then promptly transferred to childrens Hospital.

Physical examination on admission showed the child to be pale, crying constantly, and clinically in shock. Examination revealed multiple loops of small intestine protruding from the defect in the left scrotum (Figure). The blood pressure was 90 and the pulse 120. The preoperative blood chemistries were essentially negative. The child was immediately taken to surgery where it was observed that there were multiple loops of small bowel protruding through a 6 cm.-long defect in the scrotum. The testicle could be observed and appeared to be in satisfactory condition. A left-lower rectus incision was made and by traction it was possible to replace the small bowel into the peritoneal cavity until the distal ileum was encountered. At this time it was observed that the last loop of terminal ileum contained a large Meckel's diverticulum. In addition, it was apparent that the blood supply in this area was compromised. For that reason, approximately 20 cm. of terminal ileum containing the Meckel's diverticulum was resected and an anatomosis made with one row of interrupted 5-0 silk. The internal ring was then closed from within the abdomen and the defect in the mesentery closed. The defect in the scrotum was left untouched.

Figure—Multiple loops of small bowel protruding from a defect in the scrotum.

*St. Paul, Minntsota.

The abdomen was then closed with interrupted silk throughout and the child left the operating room in fairly satisfactory condition.

He did quite well for the first few days, but on the fifth postoperative day a serious bloody drainage occurred from the incision and it was apparent that a wound separation was developing. The incision was carefully strapped and this was changed at intervals. Over the next few days his general condition improved but it was apparent that a large incisional hernia had developed. However, skin eventually healed completely over this defect. He was discharged from the hospital on the thirty-fourth postoperative day, with advice to the family that he be brought to the office frequently for follow-up examinations and for incisional hernia repair at a later date. The child was subsequently admitted on February 9, 1967, with nasopharyngitis and pneumonitis. He was treated successfully with antibiotics and dismissed in eight days. At the time of his admission, the large hernial defect was again observed.

The child was re-admitted on June 6, 1968, for repair of the incisional hernia. On June 11, repair was performed, at which time multiple loops of small bowel were replaced in the peritoneal cavity and multiple adhesions were divided. The hernia defect was then carefully closed. The postoperative convalescence was quite uneventful until the ninth postoperative day when it was observed that a right inguinal hernia had suddenly developed. Because of the previous history, the child was immediately taken to surgery, and the hernia was repaired uneventfully. He was dismissed on June 24, 1968, at which time all incisions had healed satisfactorily.

He has been followed at intervals and was last examined on June 7, 1970, at which time his progress was normal and all incisions were well healed. There was no evidence of either an incisional or an inguinal hernia and both testicles could be palpated, although they were somewhat high in the scrotum.

Summary

An unusual complication from an incarcerated inguinal hernia with a successful result has been reported.

Lydate's Decision to Become a Physician

One vacation, a wet day sent him to the small home library to hunt once more for a book which might have some freshness for him: in vain! unless, indeed, he took down a dusty row of volumes with grey-paper backs and dingy labels—the volumes of an old Cyclopaedia which he had never disturbed. It would at least be a novelty to disturb them. They were on the highest shelf, and he stood on a chair to get them down. But he opened the volume which he first took from the shelf: somehow, one is apt to read in a makeshift attitude, just where it might seem inconvenient to do so. The page he opened on was under the head of Anatomy, and the first passage that drew his eyes was on the valves of the heart. He was not much acquainted with valves of any sort, but he know that *valvae* were folding doors, and through this crevice came a sudden light startling him with his first vivid notion of finely-adjusted mechanism in the human frame. A liberal education had of course left him free to read the indecent passages in the school classics, but beyond a general sense of secrecy and obscenity in connection with his internal structure had left his imagination quite unbassed, so that for anything he knew his brains lay in small bags at his temples and he had no more thought of representing to himself how his blood circulated than how paper served instead of gold. But the moment of vocation had come, and before he got down from his chair, the world was made new to him by a presentiment of endless processes filling the vast spaces planked out of his sight by that wordy ignorance which he had supposed to be knowledge.*

Campbell's Soups... wide variety...for limited appetites

Many people lose interest in food as they grow older. Some of them are fussy eaters—with only a few favorite foods. Others become indifferent to foods—because planning and preparing meals becomes a chore. Here Campbell's Soups can help —for these four very good reasons:

Appeal With a variety of tastes, textures, aromas, and colors, Campbell's Soups can add interest and appetite appeal. And they're easy to eat—ingredients are tender, bite-size. Even patients on special diets will find soups they can enjoy among the more than 50 different varieties available.

Nourishment Campbell's Soups contain selected meats and sea foods, best garden vegetables—carefully processed to help retain their natural flavors and nutritive values.

Convenience Within 4 minutes a bowl of delicious soup is heated and ready to eat.

Economy Campbell's Soups are inexpensive—an important consideration to those whose budgets are limited.

Recommend Campbell's Soups . . . and, of course, enjoy them yourself. Remember, *there's a soup for almost every patient and diet . . . and for every meal.*

the 3 phases of Eve

All women are not equal in their endogenous hormonal output. And, while all oral contraceptives are fundamentally effective, they exhibit **differences in their activity levels and estrogen-progestogen ratios that affect different women differently**—in both short and long-term use. Some brands may be insufficient for the woman's needs or else may exceed them.

Searle offers a family of O.C. products that covers the range of women's needs to help you provide the right pill for the right woman at the right time.

Progestational Agents in Clinical Practice. Med. Sci. 18:37-49 (May) 1967. **3.** Kistner, R. W. Gynecology, Principles and Practice. ed. 2. Chicago. Year Book Medical Publishers. 1971. **4.** Kistner, R. W. The Pill: Facts and Fallacies About Today's Oral Contraceptives. New York. Delacorte Press. 1968. **5.** Nelson, J. H. Clinical Evaluation of Side Effects of Current Oral Contraceptives. J. Reprod. Med. 6:50-55 (Feb.) 1971. **6.** Orr, G. W. Oral Progestational Agents. Therapy and Complications. S. Dakota J. Med. 22:11-17 (Jan.) 1969.

the Ovulen phase

Most women* with a **balanced hormone profile** and **normal menses** do best on a middle-of-the-road pill that is neither estrogen dominant nor strongly progestogen dominant.

(*Typical clues—normal body build and breasts, feminine appearance, healthy skin and hair. Vaginal cytology slide—balanced "pink and blue.")

Some women having problems on other O.C.s might do well on Ovulen.

Ovulen has a distinctive hormonal balance that combines moderate estrogenic activity with a slight progestogen dominance. It has an excellent record of patient acceptance.

Ovulen®

Each white tablet contains: ethynodiol diacetate 1 mg., mestranol 0.1 mg.

SEARLE

For brief summary of prescribing informatio
see following page.

the Demulen phase

Many women* who secrete **more estrogen** than most do well on a pill with lower estrogen activity and an increased progestogen overbalance.

(*Typical clues—shorter, plumper, full-breasted, with glowing skin and no wrinkles. Vaginal cytology slide "pink.")

Some women with special conditions that may be aggravated by higher estrogen-activity products may do better on this ratio.

Demulen combines minimal estrogenic activity with a moderate ratio of progestogen overbalance. It is particularly well suited to the young when low-dose (activity) is preferred. Demulen offers little risk of the most potent progestogen side effects; early breakthrough bleeding is often transient.

Demulen®

Each white tablet contains: ethynodiol diacetate 1 mg; ethinyl estradiol 50 mcg.
Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo containing no active ingredients.
Both Ovulen and Demulen are available in 21- and 28-pill schedules.

the Enovid-E phase

Some women* who secrete **less estrogen** than mos do best on a pill with a moderate estrogen overbalance.

(*Typical clues—oily complexion, acne, hirsutism masculinity, flat chest. Vaginal cytology slide—"blue.")

Patients with estrogen deficiency may show:

premenopausal syndrome	intermittent depressio
early-cycle bleeding	increased appetite
scanty menses	steady weight gain

vaginal candidiasis

Enovid-E not only provides increased estrogenic activity with low progestogen activity, but also contains the only progestogen that is not antiestrogenic. Therefore it offers less risk of high-dose progestogen side effects.

Enovid-E®

Each tablet contains: norethynodrel 2.5 mg; mestranol 0.1 mg

Oral contraceptives are complex medications and, after reference to the prescribing information, should be prescribed with discriminating care.

for the 3 phases of Eve:

a family of O.C. products

Ovulen®

Each white tablet contains:
ethynodiol diacetate 1 mg./mestranol 0.1 mg.

Demulen®

Each white tablet contains:
ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.

Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.

Actions—Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note—Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication—Ovulen and Demulen are indicated for oral contraception.

Contraindications—Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings—The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain[1,3] leading to this conclusion, and one[4] in this country. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll[3] was about sevenfold, while Sartwell and associates[4] in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as nonusers. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations preexisting uterine fibromyomas may increase in size. Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. Any possible influence of prolonged Ovulen or Demulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Ovulen or Demulen therapy. The age of the patient constitutes no absolute limiting factor, although treatment with Ovulen or Demulen may mask the onset of the climacteric. The pathologist should be advised of Ovulen or Demulen therapy when relevant specimens are submitted. Susceptible women may experience an increase in blood pressure following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives—A statistically significant association has been demonstrated between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals and mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function: increased sulfobromophthalein retention and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine and decrease in T^3 uptake values; metyrapone test and pregnanediol determination.

Pediatric Medicine

THE ARTICLES in this issue are the contributions of the staff of The Childrens Hospital of St. Paul. The history of this significant institution for the Twin Cities and the State is given in Robert Rosenthal's report (page 155).

The whole concept of children's hospitals is not new, since, as Rosenthal points out, children's hospitals have been on the medical scene elsewhere in the world for over 100 years. Nor is this concept entirely new in Minnesota where we have had an orthopedic hospital for children since 1897 (Gillette Children's Hospital).

To Dr. W. R. Ramsey belongs the honor of being named the prime mover who started the forces in St. Paul which led in 1957 to the construction of The Childrens Hospital. He is the Father of The Childrens Hospital of St. Paul.

It becomes evident reading the articles in this issue that the problems of pediatrics are not the same as those faced by practitioners in dealing exclusively with adults. The unique problems of pediatrics are concentrated in the prematures and the neonates, where even such time-honored medical practices as measuring fluid requirements by weight or by surface area go by the board (See Reynolds' article, page 97 and Anderson's editorial, page 137).

Whether or not we agree with the concept of separating the pediatrics department from general hospitals creating special institutions entirely devoted to pediatrics, it is obvious that this separation is here to stay with The Childrens Hospital in St. Paul in being and the children's hospital in Minneapolis scheduled to open its doors in a year or two.

The Board of Editors of MINNESOTA MEDICINE is pleased to present this pediatrics symposium in this issue. The pages of MINNESOTA MEDICINE are open to any institution in the state which wishes to present its case material in the form of articles, and occasionally even to the extent of taking over the entire issue as is done this month.

Even to those of us who deal exclusively with problems of a different age group, it is important to keep abreast of progress in the field of pediatrics since such advances as, for instance, fluid management may lead to change in adult medicine.

Diet for Juvenile Diabetes

Something Old, Something Borrowed, Something New

THERE ARE FOUR circumstances which could alter the course of human diabetes: 1. Synthesis of a human insulin for general use by diabetics, thereby eliminating the development of antibodies to beef or pork insulin; 2. Alteration of the genetic material of the diabetic individual; 3. Interference with anti-insulin systems through medication; 4. Induction in all diabetics of obsessive, compulsive behavior in following a diabetic diet, using insulin, and controlling exercise.

It is obvious that synthesis of human insulin for general use may be possible in the not too distant future; that genetic alteration and drug interference with anti-insulin systems in children is doubtful in the near future; that obsessive behavior in following diet is a utopian idea incompatible with normal existence. Therefore, for the present, we must be realistic and try to control at least some of the variables that alter control of the disease: insulin, activity, and diet.

There have been numerous studies analyzing what is meant by good control. In childhood diabetes, we strive for perfection but fall short. I call childhood diabetes "fickle diabetes" because of the great variation of activity in any one child. Absolute control is impossible. However, the proper diet is one method of obtaining relatively good control and also a better understanding of the disease by the family. The Childrens Hospital diet follows this principle.

There have been numerous diets for control of diabetes. A strict diet generally has no place in childhood unless frustration is the goal. A completely unmodified diet could be of value only if used by a very mature family. A semi-restricted diet tailored to the limits of body reserves, simple to calculate and understand, coordinated with specific insulins and a normal activity level, is a most worthwhile approach to "control." This is why The Childrens Hospital diet is a real advantage for patients. It is practical, does not impose unnecessary restrictions, and the principle of fitting the diet to the disease is used.

From a technical standpoint it is difficult to evaluate this type of diet, as there are many variables, including genetics, age differences, antibody formation, activity changes, climate differences, and personality differences. The Childrens Hospital diet is being assessed in terms of acceptance by families and the adequacy of control of the diabetes. Mrs. Miller and her staff are aware of the needs for longitudinal evaluation.

Basically, the diet does not differ from any other diabetic diet in terms of calories and percentage of carbohydrates, fat, and protein. It is different in that it is presented in terms of simple categories of food, using color combinations and chart presentations which are easy to comprehend. The diet card is pocket size and easily carried. Diet, insulin, and exercise are coordinated.

On reading Mrs. Miller's Paper,* you may be surprised at how easy it is to manage a diabetic diet. Incidentally, we are also using this diet for other clinical applications such as obesity control.

Thus one of the variables of diabetes has been made more understandable through simple communication.

The Role of the Neonatal Intensive Care Unit in Modern Medical Practice

THE FORMATION of units within hospitals for the intensive care of seriously ill newborn infants dates from the late 1950s. Such units began when pediatricians in general were beginning to change their "hands off" attitude toward the premature infant, and as they began to gain more understanding of the physiology of the neonatal period. The capabilities of the units have been extended as a result of advances in the technology of incubators, respirators and infant monitoring systems. In response, a new area of special interest, neonatology, has developed within pediatrics: Individuals specializing in neonatology, or neonatal medicine, are specially trained in the diagnosis and

treatment of the adaptation problems of newborn infants, and the diseases that they are prone to. In addition, such specialists understand the devices used in the treatment and monitoring of such sick infants. Perhaps the most important individuals in the proper functioning of any neonatal intensive care unit are the specially-trained nurses who know how to care for a severely ill infant, and who can evaluate the status of the infant and the progress of his disease on a minute-to-minute basis.

Data available now indicate that the neonatal mortality rate for hospitals with access to neonatal intensive care units is approximately 50% of those hospitals which do not refer infants to such units[1]. There are many neonatal abnormalities for which no treatment is effective and conversely, there are neonatal problems which do not require intensive diagnosis and care. However, there is a large intermediate group who can be clearly benefited by the skills that can be used by the physicians and nurses in an intensive care unit. It is the survival of these infants that has so dramatically altered the neonatal mortality rate data quoted above.

The Childrens Hospital of St. Paul has a new intensive care unit with a capacity of 20 newborns and four older children. It is very active and serves St. Paul and the surrounding communities in Eastern Minnesota and Western Wisconsin. In addition, the University Hospital and Hennepin County General Hospital have active neonatal units. Since such units require trained physicians and nurses, they can operate efficiently only in medical centers of at least moderate size, and are not feasible for small community hospitals. Ill newborn infants can be transported to the existing units, such as The Childrens Hospital, by specially equipped and staffed ambulances. However, their effective range is limited to 100-150 miles.

The only practical way to bring the benefits of such units to all babies born throughout Minnesota, lies in the establishment of regional neonatal intensive care units in various parts of the state outside of the Twin Cities, and in large population centers in adjoining states serving as referral centers for Minnesota residents. The establishment of such centers is well underway in Wisconsin, and is proving to be a practical solution to the problem of making such specialized medical care available to all infants born in the state. Planning is underway now through a new organization called "The Great Plains Organization for Perinatal Medicine" for establishment of other regional units in the upper Midwest so that the Wisconsin model can be extended to Minnesota, the Dakotas, Iowa and Nebraska. Such an organization will require the cooperation of Minnesota physicians, the state governments and the federal government, and will therefore not be easy to accomplish. However, it is the only logical and efficient way to extend the availability of such specialized facilities to all babies in our state.

John W. Reynolds, M.D.*
St. Paul, Minnesota

*Department of Pediatrics, University of Minnesota and Director of Neonatology, The Childrens Hospital, St. Paul.

Bronchial Asthma

THE ARTICLE BY Strom, Austrian, Sand, and Vaccarella* in the current issue of MINNESOTA MEDICINE is timely since all practitioners interested in chest medicine, adult and pediatric, are seeing more patients with severe asthma and status asthmaticus. More deaths are occurring in severe asthmatics. The authors have brought out the importance in the outpatient evaluation whether or not the patient can be handled effectively as an outpatient or should be admitted. These factors need to be emphasized:

1. Duration of the acute asthmatic episode. If the patient has been in an acute attack for 24 hours, chances are that he is exhausted, not coughing effectively, and dehydrated. This leads to mucous impaction syndrome, alveolar hypoventilation, and respiratory acidosis. A patient in an attack of 24 hours' duration should be admitted and monitored carefully.

2. The ability of the patient to take and retain oral medication, fluids, and nourishment.

3. State of dehydration. Hydration is most important to prevent mucous impaction. This means intravenous fluid will be necessary, up to 3 liters per day.

4. Presence of infection. Usually these are acute upper respiratory infections which precipitate the acute episode.

5. Ventilatory state and the degree of hyperinflation. One can have some idea from physical examination how well the patient is moving air. But most important is what is happening to the arterial carbon dioxide tension. If the patient in the emergency room has an elevated $PaCO_2$ with acute asthma, then this is absolutely an indication for admission and careful monitoring.

6. Current or previous steroid therapy.

7. Pollution or pollen index.

8. Current atmospheric conditions.

Oxygen therapy must be monitored closely in the patient with alveolar hypoventilation secondary to status asthma just as in the patient with alveolar hypoventilation secondary to severe emphysema. Humidified oxygen should be administered in a concentration to raise the Pa CO_2 to 60 mm. of mercury. This may be 30% or 40% oxygen.

When the patient with acute asthma becomes hyperactive, anxious, and irritable, these are signs of hypoxia and hypercapnea. Sedation is contraindicated. Under these circumstances the patient must have blood gas determinations and be considered for intubation and assisted ventilation. Alkalinization corrects metabolic acidosis but not respiratory acidosis; respiratory acidosis is corrected by adequate ventilation of alveoli as the authors have discussed.

Corticosteroids can be stopped abruptly or gradually tapered after several days provided the patient has not been on steroids prior to the acute episode. If the patient has been on corticosteroids, he must be tapered slowly to his maintenance dose whether daily or every other day.

Urinary Tract Infections in Children

GEIST AND ASSOCIATES* have been studying bladder problems in children, and have contributed several excellent papers pertaining to this subject. These articles have been concerned with neurogenic vesical dysfunction in children with meningomyelocele[1], interstitial cystitis in children[2], and in this issue, urinary bladder capacity in children. They reported that 20 per cent of children with urinary tract infections had an increased bladder capacity.

The subject of urinary tract infections in children has been covered quite extensively in the urological literature, but its importance should be re-emphasized. Urinary tract infections are frequently associated with neurogenic dysfunction or obstructive uropathy, and consequently, serious damage to the kidneys can occur if these underlying conditions are not detected and treated early. Often, no underlying condition can be found during urological evaluation. It is possible that infections in this circumstance are associated with unrecognizable neurogenic or obstructive lesions.

Geist and associates reported that children with large bladder capacities were susceptible to urinary tract infections, and suggested a method of managing these patients. Their method of determining bladder capacity measured distensibility of the bladder wall, and may not have correlated with bladder capacity recorded under more physiological conditions. Until bladder capacities in a large sample of normal children are known, it is possible that a large percentage of normal youngsters have increased bladder capacities. In support of Geist and associates, Lapides and others[3] recently reported recurrent urinary tract infections in women with infrequent voiding habits and large bladder capacities, but with no recognizable neurogenic or obstructive lesions. Geist and associates did not report the voiding habits of their patients.

Cox and Hinman[4] have demonstrated the importance of complete emptying of the bladder in eliminating bacteriuria and thereby preventing infection. Antibacterial factors in the bladder wall and mucosa are less well understood. It has been suggested that chronic overdistension of the bladder in infrequent voiders reduces blood flow to the bladder wall, and in some way interferes with its ability to cope with infection. The exact role of the enlarged bladder in urinary tract infections has not yet been established.

The authors point out that all children with recurrent urinary tract infections should receive a careful urological examination. The importance of this evaluation cannot be overemphasized. The complete evaluation includes a urinalysis, quantitative urine culture, renal function tests, voiding cystourethrography, intravenous urography, cystometry which includes determination of bladder capacity, urethral calibration, and cystourethroscopy. Permanent damage to the kidneys of children with recurrent urinary tract infections can be prevented or halted by early and complete urological evaluation followed by adequate treatment. Further clinical studies concerning this problem, such as those conducted by Geist and associates, are clearly indicated.

Newborn Respiratory Distress: A Roentgenological Approach

In the current issue of Minnesota Medicine* Dr. Hugh J. Williams has discussed the wide spectrum of medical and surgical disorders capable of producing respiratory distress in the newborn. He has emphasized that clinical signs and symptoms are similar in many of these conditions and that a definitive diagnosis can frequently be established only by a chest roentgenogram. The most important contribution of this review of the subject of newborn respiratory distress, is not so much the necessity of a careful roentgenological examination, but rather the awareness that there are over 40 different conditions that can cause respiratory distress in the newborn. If we keep in mind when we are asked to see an infant in respiratory distress that this may be due to a tension pneumothorax or massive atelectasis and utilize the positive physical findings that should be present with radiographic and arterial blood gas support, we may correct a clinical situation with thoracentesis or bronchoscopy that might otherwise have had a fatal outcome. Positive physical findings will be present (such as decreased or absent breath sounds on one side, retraction, shift of the mediastinum, stridor, unilateral wheeze, flatness to percussion of an effusion, and diffuse rales and rhonci of aspiration—to mention a few). When the positive physical findings are correlated with the emergency chest xray and comparative chest xrays if available, we should be able to differentiate the medical and surgical disorders capable of producing acute respiratory distress and initiate appropriate treatment early. I differ with the summary that the chest roentgenogram is the most valuable diagnostic measure available in determining the cause of newborn respiratory distress. The physical examination with a knowledge of the differential diagnosis and a high index of suspicion is still the most valuable diagnostic measure. The history, physical findings, emergency chest roentgenogram, and arterial blood gases utilized together can best establish the etiology of the newborn respiratory distress.

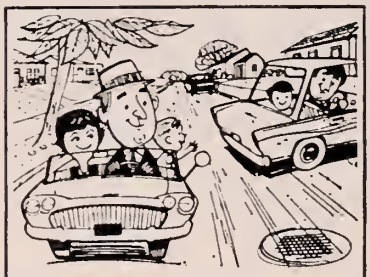
Maintenance Fluid Requirements

In this journal there is an article that relates to maintenance fluid requirements, especially in prematures and other neonates.* The author, John Reynolds, writes from a rich experience with intravenous fluid therapy in tiny babies. St. Paul Childrens has pioneered neonatal intensive therapy in this part of the country and for some time has had a nationally recognized, outstanding neonatal intensive care nursery and center.

Dr. Reynolds makes the point that the basal fluid requirements are related to the body's metabolism as well as its mass. Heretofore we have been estimating fluid requirements only by measures of body mass, namely weight or surface area. Because of the prematures and neonates' unique metabolic requirements, it is critical that body metabolism be taken into account in estimating fluid requirements.

More and more teaching centers in pediatrics are including body metabolism as a factor in determining fluid requirements, and currently there is a trend in this country to estimate all children's fluid requirements on a caloric rather than a weight or surface measure.



We are indebted to Reynolds for highlighting this refinement in pediatric fluid therapy sharing with us the importance for newborn infants that body metabolism be taken into account in determining fluid requirements.

Arnold S. Anderson, M.D.
Minneapolis, Minnesota

Happiness is a regular paycheck.

Hire a Disabled Veteran

DRIVING ON FREEWAYS is actually safer than on roads and streets close to home. Be extra alert in familiar surroundings.

Bring 'em back ALIVE!

Pre-Sate® (chlorphentermine hydrochloride)

Caution: Federal law prohibits dispensing without prescription.

Indications

Pre-Sate (chlorphentermine hydrochloride) is indicated in exogenous obesity, as a short term (i.e several weeks) adjunct in a regimen of weight reduction based upon caloric restriction.

Contraindications

Glaucoma, hyperthyroidism, pheochromocytoma, hypersensitivity to sympathomimetic amines, and agitated states. Pre-Sate (chlorphentermine hydrochloride) is also contraindicated in patients with a history of drug abuse or symptomatic cardiovascular disease of the following types: advanced arteriosclerosis, severe coronary artery disease, moderate to severe hypertension, or cardiac conduction abnormalities with danger of arrhythmias. The drug is also contraindicated during or within 14 days following administration of monamine oxidase inhibitors, since hypertensive crises may result.

Warnings

When weight loss is unsatisfactory the recommended dosage should not be increased in an attempt to obtain increased anorexigenic effect; discontinue the drug. Tolerance to the anorectic effect may develop. Drowsiness or stimulation may occur and may impair ability to engage in potentially hazardous activities such as operating machinery, driving a motor vehicle, or performing tasks requiring precision work or critical judgment. Therefore, such patients should be cautioned accordingly. Caution must be exercised if Pre-Sate (chlorphentermine hydrochloride) is used concomitantly with other central nervous system stimulants. There have been reports of pulmonary hypertension in patients who received related drugs.

Drug Dependence Drugs of this type have a potential for abuse. Patients have been known to increase the intake of drugs of this type to many times the dosages recommended. In long-term controlled studies with the high dosages of Pre-Sate, abrupt cessation did not result in symptoms of withdrawal.

Usage In Pregnancy The safety of Pre-Sate (chlorphentermine hydrochloride) in human pregnancy has not yet been clearly established. The use of anorectic agents by women who are or who may become pregnant, and especially those in the first trimester of pregnancy, requires that the potential benefit be weighed against the possible hazard to mother and child. Use of the drug during lactation is not recommended. Mammalian reproductive and teratogenic studies with high multiples of the human dose have been negative.

Usage In Children Not recommended for use in children under 12 years of age.

Precautions

In patients with diabetes mellitus there may be alteration of insulin requirements due to dietary restrictions and weight loss. Pre-Sate (chlorphentermine hydrochloride) should be used with caution when obesity complicates the management of patients with mild to moderate cardiovascular disease or diabetes mellitus, and only when dietary restriction alone has been unsuccessful in achieving desired weight reduction. In prescribing this drug for obese patients in whom it is undesirable to introduce CNS stimulation or pressor effect, the physician should be alert to the individual who may be overly sensitive to this drug. Psychologic disturbances have been reported in patients who concomitantly receive an anorectic agent and a restrictive dietary regimen.

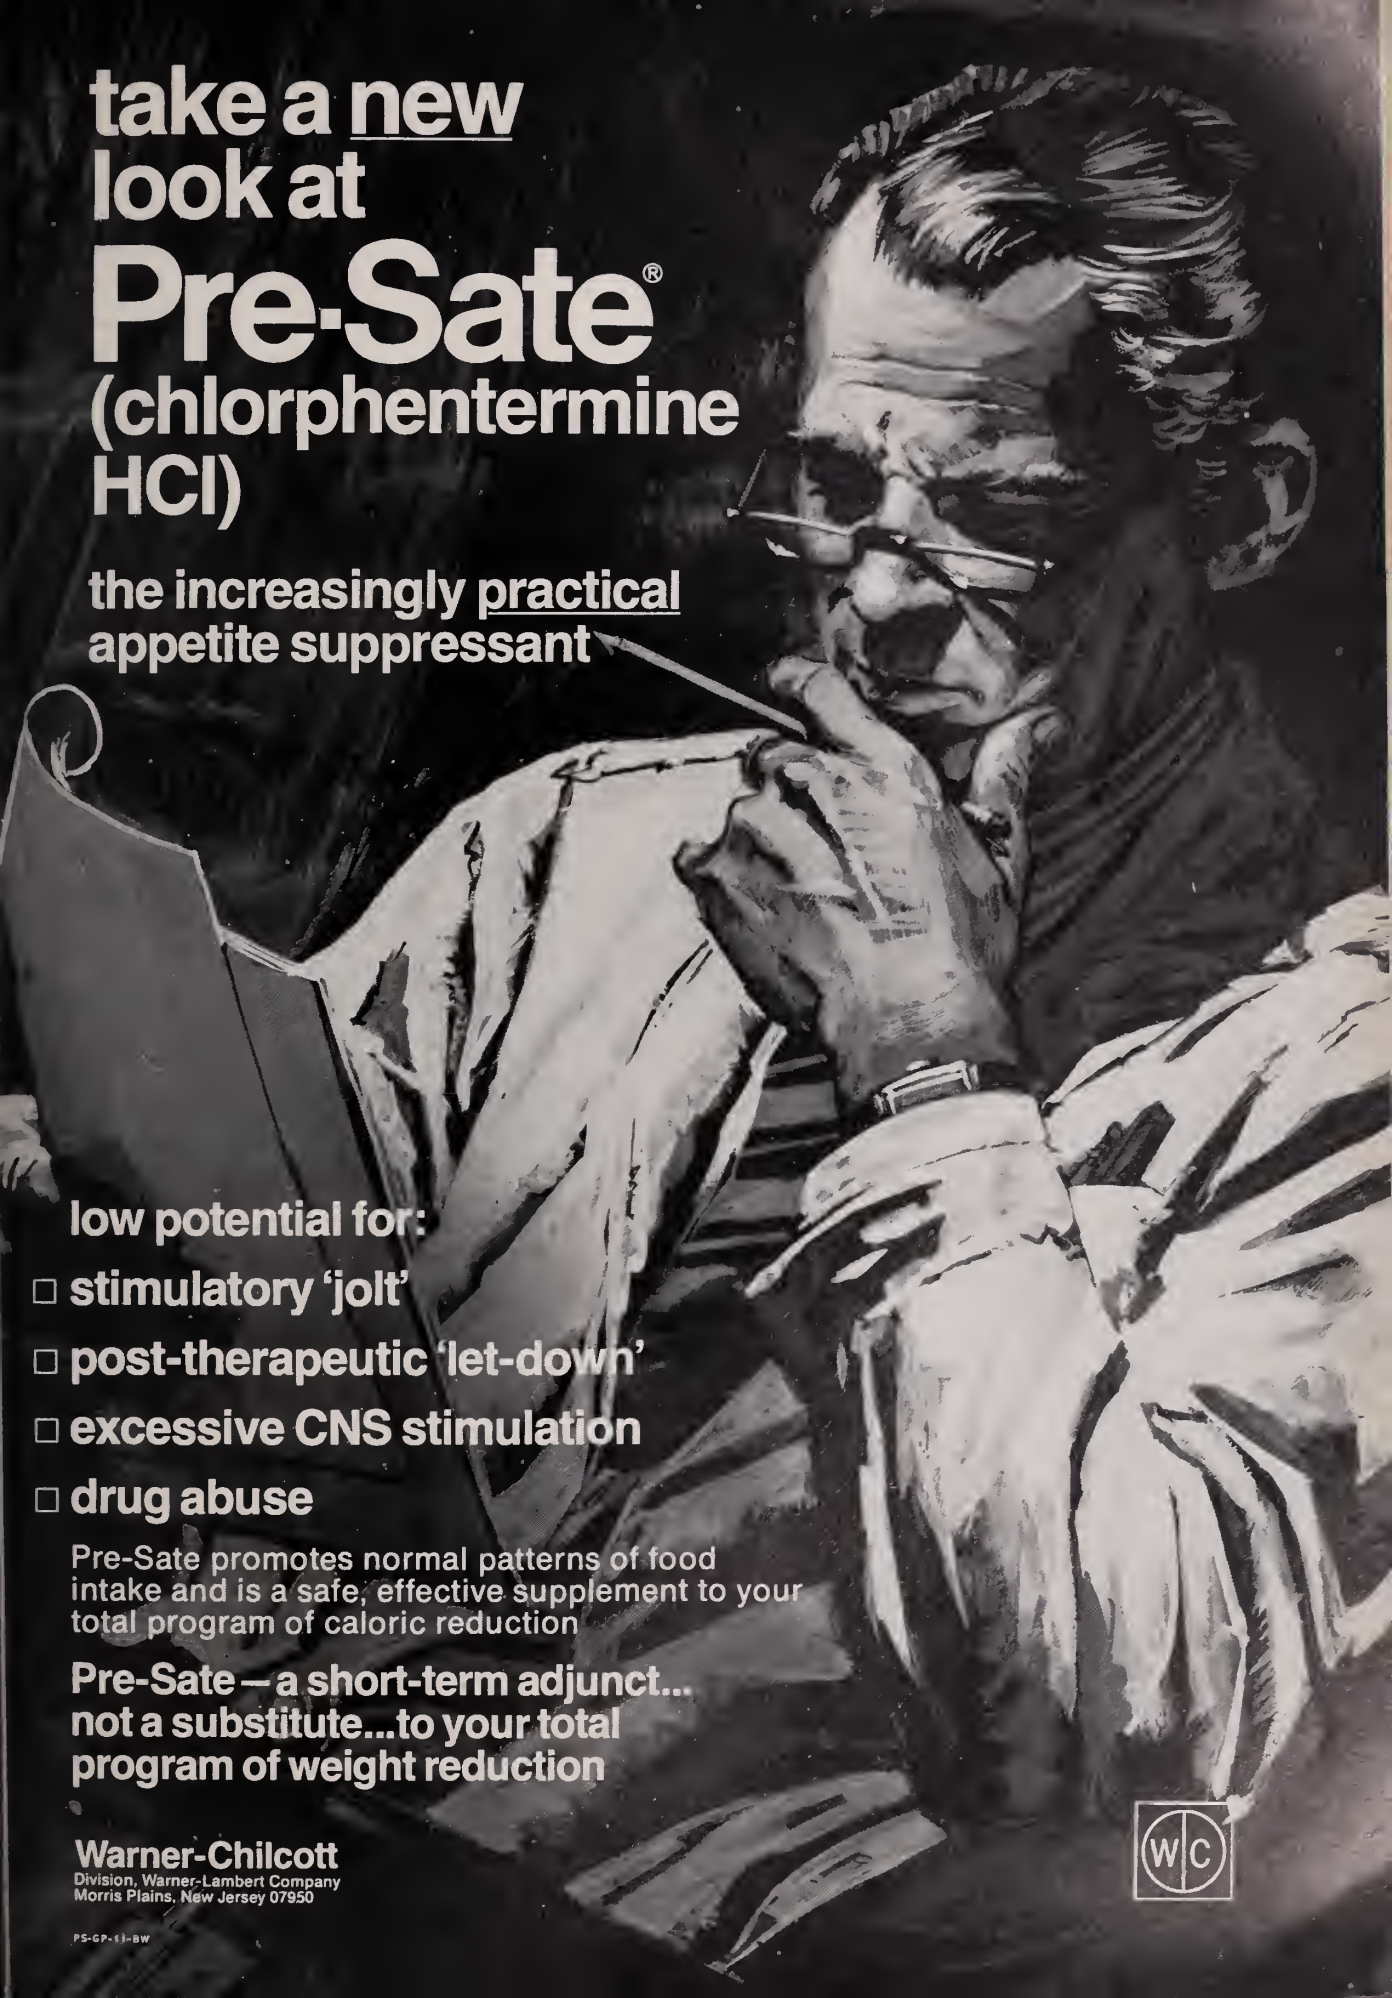
Adverse Reactions

Central Nervous System: When CNS side effects occur, they are most often manifested as drowsiness or sedation or overstimulation and restlessness. Insomnia, dizziness, headache, euphoria, dysphoria, and tremor may also occur. Psychotic episodes, although rare, have been noted even at recommended doses. **Cardiovascular:** tachycardia, palpitation, elevation of blood pressure. **Gastrointestinal:** nausea and vomiting, diarrhea, unpleasant taste, constipation. **Endocrine:** changes in libido, impotence. **Autonomic:** dryness of mouth, sweating, mydriasis. **Allergic:** urticaria. **Genitourinary:** diuresis and, rarely, difficulty in initiating micturition. **Others:** Paresthesias, sural spasms.

Dosage and Administration

The recommended adult daily dose of Pre-Sate (chlorphentermine hydrochloride) is one tablet (equivalent to 65 mg chlorphentermine base) taken after the first meal of the day. Use in children under 12 not recommended.

Overdosage



Manifestations: Restlessness, confusion, assaultiveness, hallucinations, panic states, and hyperpyrexia may be manifestations of acute intoxication with anorectic agents. Fatigue and depression usually follow the central stimulation. Cardiovascular effects include arrhythmias, hypertension, or hypotension and circulatory collapse. Gastrointestinal symptoms include nausea, vomiting, diarrhea, and abdominal cramps. Fatal poisoning usually terminates in convulsions and coma.

Management: Management of acute intoxication with sympathomimetic amines is largely symptomatic and supportive and often includes sedation with a barbiturate. If hypertension is marked, the use of a nitrate or rapidly acting alpha-receptor blocking agent should be considered. Experience with hemodialysis or peritoneal dialysis is inadequate to permit recommendations in this regard.

How Supplied

Each Pre-Sate (chlorphentermine hydrochloride) tablet contains the equivalent of 65 mg chlorphentermine base; bottles of 100 and 1000 tablets.

Full information is available on request.

WC

When you select this familiar antibiotic for IV infusion you have available a broad dosage range that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

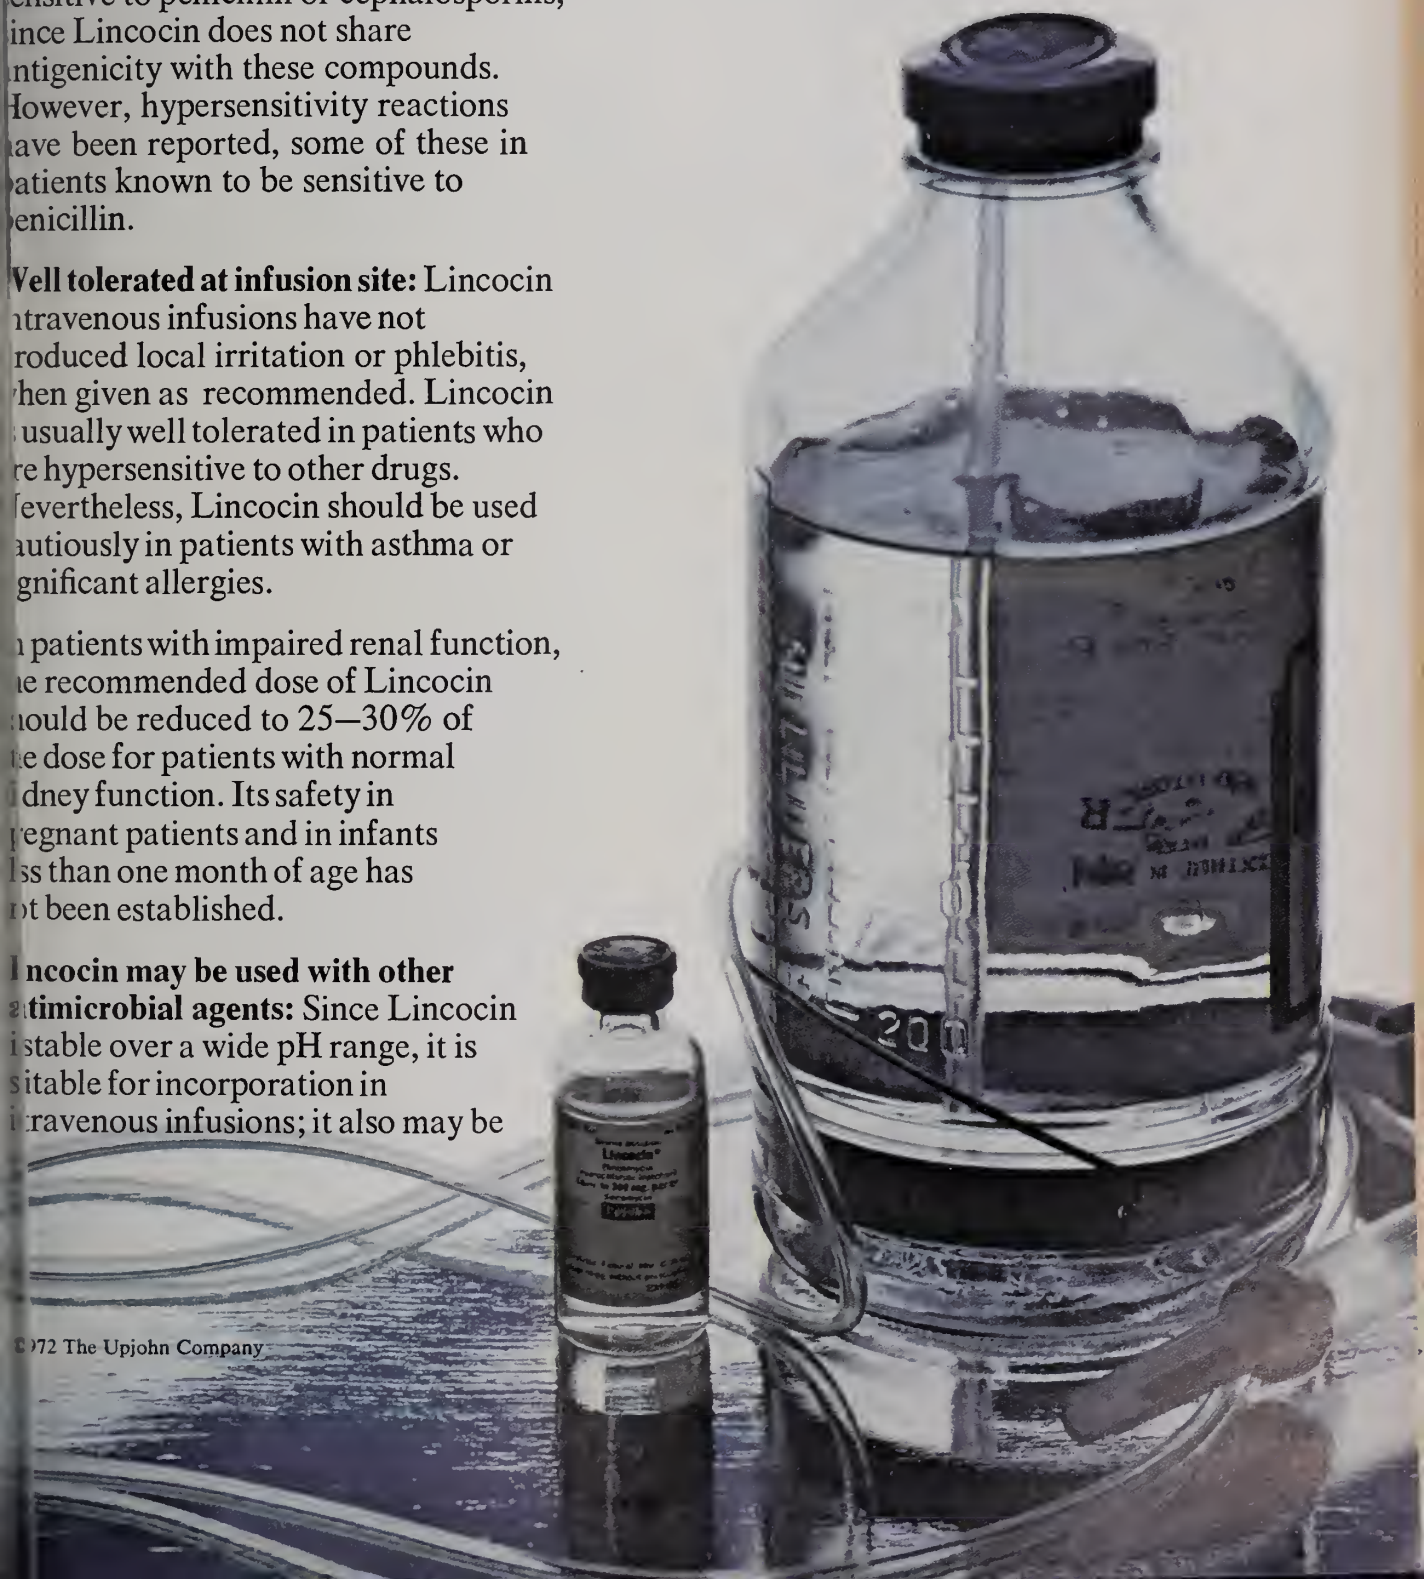
In usual IV doses, Lincocin (lincomycin hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water. But when 4 grams or more per day is given, Lincocin should be diluted in not less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

infections caused by susceptible strains of pneumococci, streptococci, and staphylococci, including penicillin-resistant strains. Staphylococcal strains resistant to Lincocin (lincomycin hydrochloride, Upjohn) have been recovered. Before initiating therapy, culture and susceptibility studies should be performed. Lincocin has proved valuable in treating patients hypersensitive to penicillin or cephalosporins, since Lincocin does not share antigenicity with these compounds. However, hypersensitivity reactions have been reported, some of these in patients known to be sensitive to penicillin.

Well tolerated at infusion site: Lincocin intravenous infusions have not produced local irritation or phlebitis, when given as recommended. Lincocin is usually well tolerated in patients who are hypersensitive to other drugs. Nevertheless, Lincocin should be used cautiously in patients with asthma or significant allergies.

In patients with impaired renal function, the recommended dose of Lincocin should be reduced to 25—30% of the dose for patients with normal kidney function. Its safety in pregnant patients and in infants less than one month of age has not been established.



Lincocin may be used with other antimicrobial agents: Since Lincocin is stable over a wide pH range, it is suitable for incorporation in intravenous infusions; it also may be administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

©1972 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®
(lincomycin hydrochloride, Upjohn)

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatment. *Skin and mucous membranes*—Skin rashes, urticaria, vaginitis, and rare instances of exfoliative and vesiculobullous dermatitis have been reported. *Liver*—Although no direct relationship to liver dysfunction is established, jaundice and abnormal liver function tests (particularly serum transaminase) have been observed in a few instances. *Cardiovascular*—Instances of hypotension following parenteral administration have been reported, particularly after too rapid IV administration. Rare instances of cardiopulmonary arrest have been reported after too rapid IV administration. If 4.0 grams or more administered IV, dilute in 500 ml of fluid and administer no faster than 100 ml per hour. *Special senses*—Tinnitus and vertigo have been reported occasionally. *Local reactions*—Excellent local tolerance demonstrated to intramuscularly administered Lincocin (lincomycin hydrochloride). Reports of pain following injection have been infrequent. Intravenous administration of Lincocin in 250 to 500 ml of 5% glucose in distilled water or normal saline has produced no local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500 mg* Capsules—bottles of 24 and 100. *Sterile Solution, 300 mg per ml*—2 and 10 ml vials and 2 ml syringe. *Syrup, 250 mg per 5 ml*—60 ml and pint bottles.

Paroxysmal Abdominal Pain in Children

ALLAN DEWALD, M.D.*

THE PATIENT, a one-year-old male, had severe abdominal pain for several hours prior to admission and two episodes of vomiting with passage of a small amount of bloody mucus by rectum. A film of the abdomen (Figure 1) indicated the presence of a soft-tissue mass partially outlined by gas in the mid-transverse colon (arrows). Several moderately gas-distended loops of terminal ileum were present.

Following this film the child became asymptomatic and fell asleep. Two hours later there was a recurrence of symptoms and a barium enema was performed. In the left transverse colon an intraluminal mass was encountered which preceded the barium column to the cecum. No barium refluxed into the terminal ileum. A post-evacuation film (Figure 2) demonstrated a mass in the ascending colon partly delineated by a coil-spring type of barium distribution.

What is your diagnosis? (See next page.)

*Rapid City, South Dakota.

Fig. 1—The admission abdominal film demonstrates a soft-tissue mass outlined by gas in the transverse colon (arrows).

Fig. 2—The post-evacuation film following barium enema demonstrates a large intraluminal mass in the ascending colon with a typical "coil spring" configuration. The appendix is filled with barium but there is no terminal ileal filling.

Diagnosis

The mass represents the head of an ileocolic intussusception which was only partially reducible by the barium enema. Surgical reduction was immediately performed. No lead point for the intussusception was demonstrable.

Discussion

Intussusception is a telescoping of one loop of bowel into another. It most commonly originates in the distal ileum and may cause mechanical small bowel obstruction. Sixty percent of intussusceptions are ileocecal, thirty percent ileocolic, with the remaining ten percent composed of ileo-ileal, ileo-ileocolic and colocolic varieties. Transient ileocolic intussusception undoubtedly occurs more frequently than is generally appreciated and probably constitutes a common cause for indeterminate intermittent abdominal pain in children.

Eighty-five percent of intussusceptions occur between six months and two years of age and is twice as frequent in males as in females. In infants and children the cause is most often idiopathic. Adenoviral infections of the intestinal tract may precipitate intussusception by causing hypertrophy of Peyer's patches and hypermotility of the gut. A lead point is demonstrable in less than two percent of infants under two years of age. Beyond this age a lead point is more commnly found, including in order of frequency, Meckel's diverticulum, polyp, lymphoma, duplication cyst and small bowel hematoma (Henoch-Schoenlein purpura, hemophilia or leukemia).

Clinically, intussusception is characterized by the sudden onset of paroxysmal abdominal pain and vomiting. During bouts of pain the child is often pale and "shocky" but becomes asymptomatic between paroxysms. Early the abdomen is stiff and hard during attacks, only to become soft and relaxed between paroxysms of pain. The soft tissue mass of the intussusception is sometimes palpable, particularly during periods of relaxation. Rectal bleeding is uncommon in early intussusception and only 50 percent will demonstrate this finding (currant jelly stool) by 24 hours. Rarely will the intussusception protrude through the rectum and simulate rectal prolapse.

The abdominal roentgenogram may be non-contributory in intussusception. Commonly, however, there is an absence of gas in the right half of the colon. The soft-tissue mass of the intussusception will be outlined by colon gas in 20 percent of patients. Gas and fluid-filled small bowel loops will be evident if significant mechanical obstruction is present. However helpful the plain films may be, the barium enema is the most definitive diagnostic procedure. It will often demonstrate the characteristic coil-spring pattern due to permeation of barium between the intussusceptum and the intussuscipiens. In addition to being diagnostic, the enema can be employed therapeutically to successfully reduce up to 80 percent of early cases. Hydrostatic reduction should not be attempted in cases with evidence of peritonitis or severe small bowel obstruction. Even if the intussusception is incompletely reduced hydrostatically, the procedure is valuable since it simplifies subsequent surgical reduction. Because a successfully reduced intussusception may recur with evacuation, a post-evacuation film should always be obtained to check for recurrence.

Discretion in speech is more than eloquence.—Bacon

Family Practice

How Do I Take Care of My New Baby, Doctor?

ALBERT G. MILLER, M.D.

TWENTY YEARS AGO this question would have worried me greatly for no one in my medical school or post graduate year took time to include this basic knowledge in my pediatric training. If this same mother had asked me how to treat her child with tuberculour meningitis, syphilis or leukemia, I could have quickly and calmly outlined the available therapy.

Today I can answer her first question with promptness and assurance, but contact with the medical students and house officer at Childrens Hospital has convinced me that their exposure to this basic pediatric problem is no better than mine a generation ago. The modern pediatrician would probably answer her question with, "Mrs. Jones, let me introduce Miss Smith, my pediatric nurse practitioner. She will answer all your questions about your new baby."

After opening a private practice with a paucity of practical knowledge, one must collect this essential learning through questioning older colleagues, by trial and error care of his own children, in reading practical literature and by growing from your patients' experiences and comments as you guide them with decreasing ignorance.

As you mature, you develop certain clinical impressions upon which you add, modify, or discard as your dialogue with mother takes form. One hesitates to put them into writing for my impressions may solve problems in my practice, but perhaps they may not withstand the critical analysis of colleagues and mentors. Yet, these answers to practical questions may help the new pediatrician gain the confidence of his mother and rapidly increase his practice.

If one organizes his daily visits to the new mother, he will not sound like a broken record repeating what he just explained to another mother on the maternity floor. He will know what he will discuss with her today, what he will tell her tomorrow, what he will tell a second new mother that same day, and so on through the mother's post partum stay in order to tell each the complete story without needless repetition and without overburdening her with too many new facts in one visit. One needs to modify his presentation for the mother who appears anxious and overwhelmed by her new situation, and needs more discussion and reassurance, but the basic dialogue remains fairly constant. (The only thing that throws me into slight panic yet is finding on the third morning that the obstitrician has promised the yet unengorged nursing primipara that she may go home today.)

The thorough, though busy, pediatrician must visit daily spending five or ten moments helping her gain confidence in herself and in turn in him. It is time well invested to enable the mother and child to go home knowing each other to a fuller degree, and there will be many fewer telephone calls at all hours frantically seeking help.

You must decide that you like this facet of pediatric practice, for when five hundred new babies enter your practice each year, a certain portion of your available office appointments need to be held open for the five or six well-baby visits required the first year of life. It can be a very gratifying experience as well as a financial asset for your practice.

In 1970 five hundred and one newborns were seen. The majority were normal infants but problems such as prematurity, multiple births, hyperbilirubinemia, hyaline membrane disease, infants of diabetic mothers, tetany, chromosome abnormalities, congested heart disease, craniosynostosis, imperforate anus, nerve palsier, sepsis, scalded skin syndrome, and minor orthopedic problems such as club feet and fractured clavicles produced a high enough incidence of pathology to keep one observant, stimulated and studying.

Two hundred thirty-nine mothers chose to nurse while 241 preferred to use a formula. An

additional 10 infants died within a few hours of birth from prematurity or severe respiratory distress, so these mothers had no opportunity to denote a feeding preference. A final 11 newborns were so premature that I chose to use a 24-calorie iron fortified formula rather than giving the mother the option to try breast feeding.

Thus, roughly, fifty percent chose to nurse their infants. Five nursing mothers did not return for follow-up care, but of the others, only ten had discontinued nursing at the one month's visit.

The decision to nurse must be made by the mother before the time of delivery. To enjoy nursing she must be enthusiastic in her decision. If her nine months of pregnancy have not given her sufficient time to decide resolutely in the affirmative, perhaps guilt feelings or family pressure are pushing her toward an unhappy choice. Give her emotional support by pointing out that her baby can grow both physically and psychologically on a par with a breast-fed infant. She can be just as much the complete, loving mother feeding him by bottle if she holds, cuddles and loves him each time.

For the mother whose joy is in nursing, enthusiastically second her decision at your first meeting, and then support her the following days when the discouragement of a sleepy baby and the discomforts from stitches and engorgement weigh heavily against her initial choice.

Advise the mother that her baby is expected to lose the next several days as he will be voiding and dirtying his diapers many times before he begins to eat enough. It may be a week or more before he gets back to his birth weight and it is possible the baby will not gain it all before he goes home.

The mother should be told the baby will be breast fed every three to four hours. If he is sleepy, a few drops of cold water on his forehead are more likely to awaken him than will pinching his cheek or slapping his bottom. She should support her breast with one hand, pulling it back from the nipple with her thumb and forefinger. This will make the breast easier to grasp and will also keep the breast away from his nose and allow him to breathe. Touching his cheek to the nipple will help him find the nipple. He should get a good mouthful of breast including part of the colored area. When he is to be removed, first break the suction by pulling his chin down or by gently prying the corner of his mouth from the breast. Just tugging him off will soon produce a sore nipple.

Let him nurse up to three minutes on each breast the first day and just four minutes the next day. This gradual start will stimulate breasts to produce milk in two or three days without letting nipples become cracked or painful. There will be no formula as he does not need the calories at this stage. The formula will decrease his urge to nurse, for the milk comes far more easily from the bottle than the breast.

Through trial and error the mother will determine how often the baby needs to be burped. If he spits up when burped after the first three minutes, do it more frequently until the baby learns to swallow less air in the succeeding days. There is no harm in not burping, although he is more apt to spit up some milk later, or perhaps he may sleep longer if he gets the air up promptly and replaces it with additional milk.

Once milk comes in the mother will be waiting for the baby to relieve the discomfort of her engorgement.

In regard to diet, unless a food upsets the mother, it is rare that it will bother the baby. There are a few foods to watch, however. In eating chocolate take a few pieces rather than eating half the box at one time. As for spicy foods, start with a small pizza instead of the king-sized one. Some people do have trouble with gassy foods, such as beans, onions, cabbage, and cauliflower, so moderation can be observed through taking only one serving a day. Drinking large amounts of milk, beer, or tea will not increase your milk supply.

Bromides pass into your milk in large amounts but barbituates do not. Sulfa may come through in harmful amount, but penicillin and other antibiotics will not. Aspirin and Darvon will cause no harm, but ergot in migraine tablets can be dangerous. The caffine in your coffee and alcohol in moderation will do no harm, but more than a few cigarettes may reduce the milk production but the nicotine will not affect the baby. If you need to take cortisones, it is recommended that one discontinue to nurse. Ordinary laxatives such as mineral oil, milk of magnesia, X-lax, and senna are safe, but cascara and Dovbane may cause trouble.[3]

Most babies are alike in having extra mucus

the first days. They rattle and gag on it and often end up regurgitating it. The mother should call the nurse and she will clean him up for you. Babies get lint up their nose and sneeze every now and then. It is the only way they can blow out the tickles and it is not the onset of a cold. Babies hiccup frequently often after each feeding. It is just a harmless jumping of his diaphragm, and a swallow or two of water often stops it. Otherwise, after several minutes they will cease by themselves.

Over the years it has become necessary to mention the sneezing and the hiccuping or the mother will raise the question sooner or later—often by telephone after getting home. If the inevitable regurgitation of mucus or colostrum is belittled before it occurs, the mother will be more completely satisfied than if the same explanation is given post facto.

Even if it is not her first baby, mention the point of individuality. Ask her to forget how her last baby ate or slept or cried for even brothers and sisters don't behave the same like peas in a pod. The only real difference is that a baby boy wets many more diapers a day than will his sister. But, any other variation in physiological responses, temperament, and activity pattern is just due to two different personalities independent of sex.

For a formula feeding, standard brand, eight-ounce, wide-mouth, pyrex bottles are recommended. The terminal method of sterilization with emphasis on the need for an adequate period of boiling (twenty-five minutes of active boiling) and the necessity of using adequately cleaned equipment should be stressed.

The first two or three bottles should be just sugar and water. Following this period the baby will be offered formula if he is awake enough to want some. After the initial twenty-four hours offer an ounce of Enfamil, and this should be increased each day. The gradual approach will give the digestive tract time to adjust. Give the baby sugar water, in addition if he indicates he wants more liquid than the formula offered.

At home start with four ounces in his bottle and let the infant take what he wants over a twenty minute period plus adding on time taken for burping. Hold the bottle at an angle that keeps the nipple full of milk. As soon as he or she can drain the whole amount, increase the bottle by one ounce the next day so as to keep one jump ahead of him. We seldom go beyond eight ounces, for by that time he will be old enough to try some solid food. Do not keep formula leftover for the next feeding. Too many bacteria will accumulate to make it unsafe.

Some vigorous babies can empty a breast in two minutes while the average infant takes four to five minutes; but most of them enjoy sucking at the empty breast for a longer period. But, after ten minutes excessive air swallowing occurs, and the probability of developing a sore, cracked nipple increases.

The baby may become quite sleepy after emptying the first breast. It is entirely possible he will be completely satisfied with just one breast. Nursing time can vary from two to five minutes on one breast up to a total of twenty minutes on both breasts.

Within reason a baby can establish his own feeding schedule, but he will have to learn to wait at least three hours from the start of one feeding to the start of the next, or the mother will be spending all her time just feeding and changing the baby. If he can sleep four hours or more, let him. In the beginning, wake him at the end of four and one half hours during the day, or too long a nap might get his days and nights reversed and have the mother up every two hours at night. Let the infant sleep as long as he will at night. As soon as he regularly sleeps at least eight hours at night, gradually lengthen out the feeding intervals during the day. Some sleep through the first night at home, while others just as normal, will be four months old before they omit the two A.M. feeding. At three months some babies are down to three feedings, while others are still nursing eight times around the clock, but 90 percent are good sleepers by that time.[5,6,7]

The mother should be relaxed at nursing time to enable the let-down reflex to occur. This reflex helps the baby get the milk. Normally, sucking causes a hormone to enter the mother's bloodstream. This acts on the tiny milk sacs in the breasts to make them squeeze the milk into the bigger ducts where it can be sucked out. Sometimes just thinking about it will start the milk letting down and dripping from the breasts. Tension, worry, and especially pain from the tender nipple can interfere with this most important reflex.[10]

(I have never found it necessary to use Syntocinon nasal spray to stimulate this reflex. If

one takes time to visit the mother, offer advice, answer her questions, and allay her fears sufficient natural hormone will be secreted to elicit a satisfactory let down.)

After feeding, a baby should be put to bed on his abdomen, so that any milk spit up will end up on the sheet and not in his lungs. A second important reason for this position is that if left sleeping on his back, he will keep his head turned to the same side the first four months. Just the weight of his head will push the soft skull bones out of shape creating a lop-sided appearance both in the back and on his forehead, with one ear edging an inch ahead of the other. Kindergarten exam time reveals that these changes in shape can be permanent.

Do not have the crib in your bedroom. His cry of hunger or wet diaper will be easily heard.

Too many covers might result in a heat rash. Start with a six-year crib right away, for the limited circulation of air in a bassinet or cradle helps promote overheating him.

At first bowel movements are thick, black and sticky, and appear during each feeding. Later they will become much looser. Most babies go on to have yellow or orange stools in a few days. But, in some infants this transitional pattern can persist two or three weeks with the stools remaining green and often being explosive. They can also contain mucus, and may occur frequently.[13]

If he grunts and groans, turns red or purple, thrashes about or even cries when his loose movement squirts out, help him by inserting a finger or a thermometer into his rectum.

The consistency of his stools can vary from hour to hour or from day to day with some being mainly water, some watery and curdy and some pasty; but it will be unlikely but not impossible that he will have a formed stool. As the days go by his stools may gradually decrease in number and there may be days with no stools at all.

The Committee on Nutrition of the American Academy of Pediatrics has recently re-emphasized it's recommendation that iron-fortified proprietary formulas be used to prevent iron-deficiency anemia of infancy. In addition, the Committee suggests it be used "as beverage milk until the infant is at least 12 months of age."[14] Except in the case of a premature birth, a baby with low birth weight, multiple births, or an infant of an anemic mother use the standard, concentrated liquid form without added iron. Each year the author finds more than one or two of his infants at the age of 12 months having a hemoglobin under 9.5 gm%. The majority have a hemoglobin value of 11.5 gm% or above. Therefore, there is no need for the added iron for the average baby. The parents have difficulty in getting their grocer or druggist to obtain the iron-fortified formula. Too frequently it takes much insistence to keep the baby on formula for four months, so it is doubtful that a mother can be convinced she should use formula for a full year. In addition there is a price factor involved with twenty-six ounces of formula costing thirty-one to thirty-three cents and a half gallon (64 oz) carton of whole milk varying from forty to forty-eight cents.

Some mothers use a proprietary formula other than Enfamil, because they used it previously or heard of it from a friend. Rarely, an older mother still prefers to use an evaporated milk formula that she made for all her older babies.

Start some vitamin C and D when he is two-weeks old. Our water contains a small amount of fluoride to help build stronger teeth, but since most breast-fed babies take little or no water a fluoride supplement is needed.[15]

Fill a plastic dropper up to the 0.6 mark, put it way back on his tongue and the baby will swallow it slowly down his throat. It can be given at any time of the day, but get in the habit of doing it at the same time each day, for developing the habit will keep you from forgetting these essential nutrients."[17] (The formula used by Mrs. Brown has an adequate supply of vitamins only when Robert drinks a full can each day. Mrs. Brown will use 0.3 cc of Trivisal to guarantee an adequate amount without excessive waste. The water used to mix the formula supplies sufficient fluoride.)

Solid food can be started at the age of one month. A baby does not need it before he is four or five months old,[18] nor does it mean he will sleep any longer, nor grow any faster.[6,7,8] At their proper time solids are needed to supply iron which is completely lacking in milk. Some babies absolutely refuse food at first, but all will accept it by the age of five months if no one has panicked and tried to force feed them.

Start with fruit either applesauce, bananas or pears rather than cereal. Feed him the fruit twice a day. Babies seem to prefer the taste (or feel) of fruit, they develop fewer allergic problems; and they seem to get less fat and overweight. Their

intestinal tracts do not supply an adequate supply of digestive enzymes from their pancreas to properly digest starches the early months of life.[19,20] Some experts feel the introduction of wheat or rye too early in life may produce diarrhea due to sensitivity to gluten.[18]

It is not necessary to specially prepare baby food which has a high cost (4¾ ounces of applesauce for 12 cents versus 50 ounces of good adult brand for 59 to 69 cents), often contains allergy-producing citrus juices or fruits and may be diluted with tapioca, noodles or flour. Combined foods do not allow one to spot what item is producing the new-rash, stomachache or diarrhea.

At ten days, start giving him a bottle at least once a week. Without experiencing an occasional bottle of formula he may stubbornly refuse it when you do wish to skip a feeding or when you decide to wean him. Offering a bottle of water is not an adequate substitute, for even if he accepts the water, he may still refuse formula. If an entire nursing is substituted, let him take what he wants during a twenty-minute feeding. The first bottle or two may be accompanied by some spitting up, until he gets used to that type of nipple.

Enfamil is one of the many good formulas manufactured to imitate breast milk. For the occasional feeding the ready-to-use bottles are a convenience; they are sterile; and they need no refrigeration. Remove the cover, screw on a standard nipple and his bottle is ready; unless the baby has become too accustomed to the warmth of breast milk and sulks until the formula is warmed. Most stores stock them in three sizes—four, six, and eight ounces. The bottles may be reused, but of course any leftover must be discarded.

Some mothers prefer to offer a bottle each evening so as to encourage their husbands to take over the 10:00 P.M. or 2:00 A.M. feeding. At that frequent use powdered formula is more economical than nursettes. If the formula is given immediately after its preparation, sterilization is not necessary. Terminal sterilization is mandatory if the formula will not be used within thirty minutes, however.

Each diaper change, both for urine and stool, calls for use of both soap and water in that area. A full bath does not need to be a daily ritual only when the need is evident whether it is twice a day or once a week. There is no scientific reason for doing it in the morning, and an evening bath may be more relaxing and sleep producing. It will also give the father a chance to bathe him. Nor does it matter whether it is done before or after a feeding.

We use a purple dye on the baby's cord. It prevents infection and delays the separation of the cord for up to three or four weeks. Tub the baby as soon as he gets home, but dry the area thoroughly after his bath. If the stump becomes sticky, you can wipe about its base firmly with cotton and alcohol three or four times a day. Do the same thing if the navel spots any blood for a day or two after the cord drops off. No belly bands or dressings need be used.

In the nursery Phisohex is used to prevent the more resistant hospital bacteria from causing skin infections. In the home environment, use ordinary soap such as Ivory or Lux, rather than the medicated soaps, such as Dial, Safeguard, Lifebuoy, Phase III, Zest, Phisohex, etc. Hexachloraphene, the halogenated salicylanilide, and similar disinfectants found in these soaps tend to dry a baby's skin after repeated use, and for some it can cause a contact dermatitis or severe skin reaction when exposed to sunshine.[21,22,23,24] Some experts feel there may be harm done in killing off the everyday bacteria on our skin, for more pathogenic bacteria or fungi may then invade and cause disease.[21,26] Ivory is more economical also.

If cradle cap develops rub some vaseline in well at bedtime, shampoo the next morning and rub out the scales with the towel or washrag. Repeat this for a few days until all the scales are gone, and then do it again in a few days, a week, or a month later when it returns. If the baby has long hair, the vaseline is too difficult to wash out, and it is necessary to use the more expensive Fostex cream shampoo or Head and Shoulders.

If winter weather or too frequent bathing leads to development of dry skin, use Nivea cream in place of oils or lotions.[27]

Baby powder or cornstarch can be used in the diaper region if a mild irritation develops. That area will remain cooler and less irritated if snap-on pants are used rather than the pull-on plastic or rubber pants.

In the summer air conditioning is used in the hospital and should be used at home for comfort if available, but a fan or a breeze through an open window can be substituted. Wind on his face does not make increased air swallowing

("gas"). It is an old wives' tale that wind on his ears causes an earache. The more he gets outside, the better he will sleep.

The first few months he has built-in protection in the form of antibodies from you, against seldom seen diseases such as diphtheria and polio, but he has no such defense against the common cold, strep throat, or the ever-present flu. A cold may not develop into anything serious, but if the small-sized nose gets plugged the baby will have difficulty in nursing and sleeping, so his fussy periods will increase in frequency and length.

If circumcised, no vaseline or dressing is needed to protect it from the diaper. Wash the penis during his bath and when you change his diapers. Soap and water will not hurt it. If the circumcision was extra short leaving a raw area on the shaft, have the mother apply vaseline there for a day or two. The average mother (or father) will not retract the swollen foreskin remnant even if directed to do so. At the six week exam any adhesions that have reformed between the corona and foreskin can be easily broken down with less trauma for the parents.

At home some babies behave miraculously for a few days and then on the fourth or fifth day spend most of their time crying. If no one gets too upset, peace usually returns the next day. A car ride will often quiet a noisy baby, for the engine vibration seems to lull him back to sleep at once. The sound of a vacuum cleaner, the hum of a radio tuned away from any station or the buzzing of an electric razor may also solve a crying situation. Occasionally, holding the side of the vibrating razor against the baby brings results when the sound alone has no effect.

A pacifier is also a handy gadget that entertains and quiets a baby if he cannot find his thumb. A nipple plugged with cotton often does better than the fancy commercial article that has a handle which catches the baby's waving hand and is repeatedly knocked from the mouth.

Don't be too anxious to start on the pill again. The hormones may make your milk supply decrease or even disappear. Nursing does not guarantee the mother she will not become pregnant again. It is unlikely that she will conceive until the baby is ten weeks old, unless she has a menstrual period before that time.[28]

The first days at home the mother will find herself tiring easily. Her milk supply will decrease somewhat for about forty-eight hours, but it will rebound again to very adequate levels. Without the nurses near, she may well become apprehensive, and develop some blues, but self-confidence will increase as the days go by.

The girth control pill

Tepanil® Ten-tab®

(continuous release form)

(diethylpropion hydrochloride, N.F.)

When girth gets out of control, TEPANIL can provide sound support for the weight control program you recommend. TEPANIL reduces the appetite—patients enjoy food but eat less. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation.

Controindicotions: Concurrently with MAO inhibitors, in potients hypersensitive to this drug; in emotionally unstable potients susceptible to drug obuse.

Worning: Although generolly sofer thon the omphetomines, use with greot coution in potients with severe hypertension or severe cardiovosculor diseose. Do not use during first trimester of pregnoncy unless potentiol benefits outweigh potentiol risks.

Adverse Reoctions: Rorely severe enough to require discontinuotion of therapy, unpleosont symptoms with diethylpropion hydrochloride hove been reported to occur in relotively low incidence. As is chorocteristic of sympothomimetic ogents, it may occosionolly couse CNS effects such as insomnio, nervousness, dizziness, onxiety, ond iitteriness. In controst, CNS depression hos been reported. In o few epileptics on increose in convulsive episodes hos been reported. Sympothomimetic cordiovoscular effects reported include ones such os tochycordio, precordiol poin, orrhythmio, polpitotion, ond increosed blood pressure. One published report described T-wove chonges in the ECG of o heolthy young mole ofter ingestion of diethylpropion hydrochloride; this wos on isoloted experience, which hos not been reported by others. Allergic phenomena reported include such conditions os rosh, urticorio, ecchymosis, ond erythemo. Gastraintestinol effects such as diorrheo, constipotion, nouseo, vomiting, ond obdominol discomfort hove been reported. Specific reports on the hemotopoietic system include two eoch of bone morrow depression, ogronulocytosis, ond leukopenio. A voriety of miscelloneous odverse reoctions hove been reported by physicions. These include complaints such os dry mouth, heodoche, dyspneo, menstruol upset, hoir loss, muscle poin, decreosed libido, dysurio, ond polyurio.

Convenience of two dosoge forms: TEPANIL Ten-tob tobletsꞏ One 75 mg. tobletdoily, swollowed whole, in midmorning (10 o.m.); TEPANILꞏ One 25 mg. tobletthree times doily, one hour before meols. If desired, on additionol tobletmoy be given in midevening to overcome night hunger Use in children under 12 yeors of oge is not recommended.

Painful night leg cramps...

unwelcome bedfellow for any patient– including those with arthritis, diabetes or PVD

- Prevents painful night leg cramps
- Permits restful sleep
- Provides simple convenient dosage— usually just one tablet at bedtime

Prescribing Information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** Quinamm is contraindicated in pregnancy because of its quinine content. **Precautions/Adverse Reactions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

Division of Richardson-Merrell Inc.
Cincinnati, Ohio 45215

Trademark: Quinamm

Quinamm

(quinine sulfate 260 mg., aminophylline 195 mg.)

Specific therapy for night leg cramps.

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

Indications: Upper respiratory congestion and hypersecretion associated with: the common cold; acute and chronic sinusitis; vasomotor rhinitis; allergic rhinitis (hay fever, "rose fever," etc.).

Contraindications: Hypersensitivity to any component, concurrent MAO inhibitor therapy; severe hypertension; bronchial asthma; coronary artery disease; stenosing peptic ulcer; pyloroduodenal or bladder neck obstruction. Children under 6.

Warnings: Advise vehicle or machine operators of possible drowsiness. Warn patients of possible additive effects with alcohol and other CNS depressants.

Usage in Pregnancy: In pregnancy, nursing mothers and women who might bear children, weigh potential benefits against hazards. Inhibition of lactation may occur.

Effect on PBI Determination and I^{131} Uptake. Isopropamide iodide may alter PBI test results and will suppress I^{131} uptake. Substitute thyroid tests unaffected by exogenous iodides.

Precautions: Use cautiously in persons with cardiovascular disease, glaucoma, prostatic hypertrophy, hyperthyroidism.

Adverse Reactions: Drowsiness, excessive dryness of nose, throat or mouth; nervousness; or insomnia. Also, nausea, vomiting, epigastric distress, diarrhea, rash, dizziness, weakness, chest tightness, angina pain, abdominal pain, irritability, palpitation, headache, incoordination, tremor, dysuria, difficulty in urination, thrombocytopenia, leukopenia, convulsions, hypertension, hypotension, anorexia, constipation, visual disturbances, iodine toxicity (acne, parotitis).

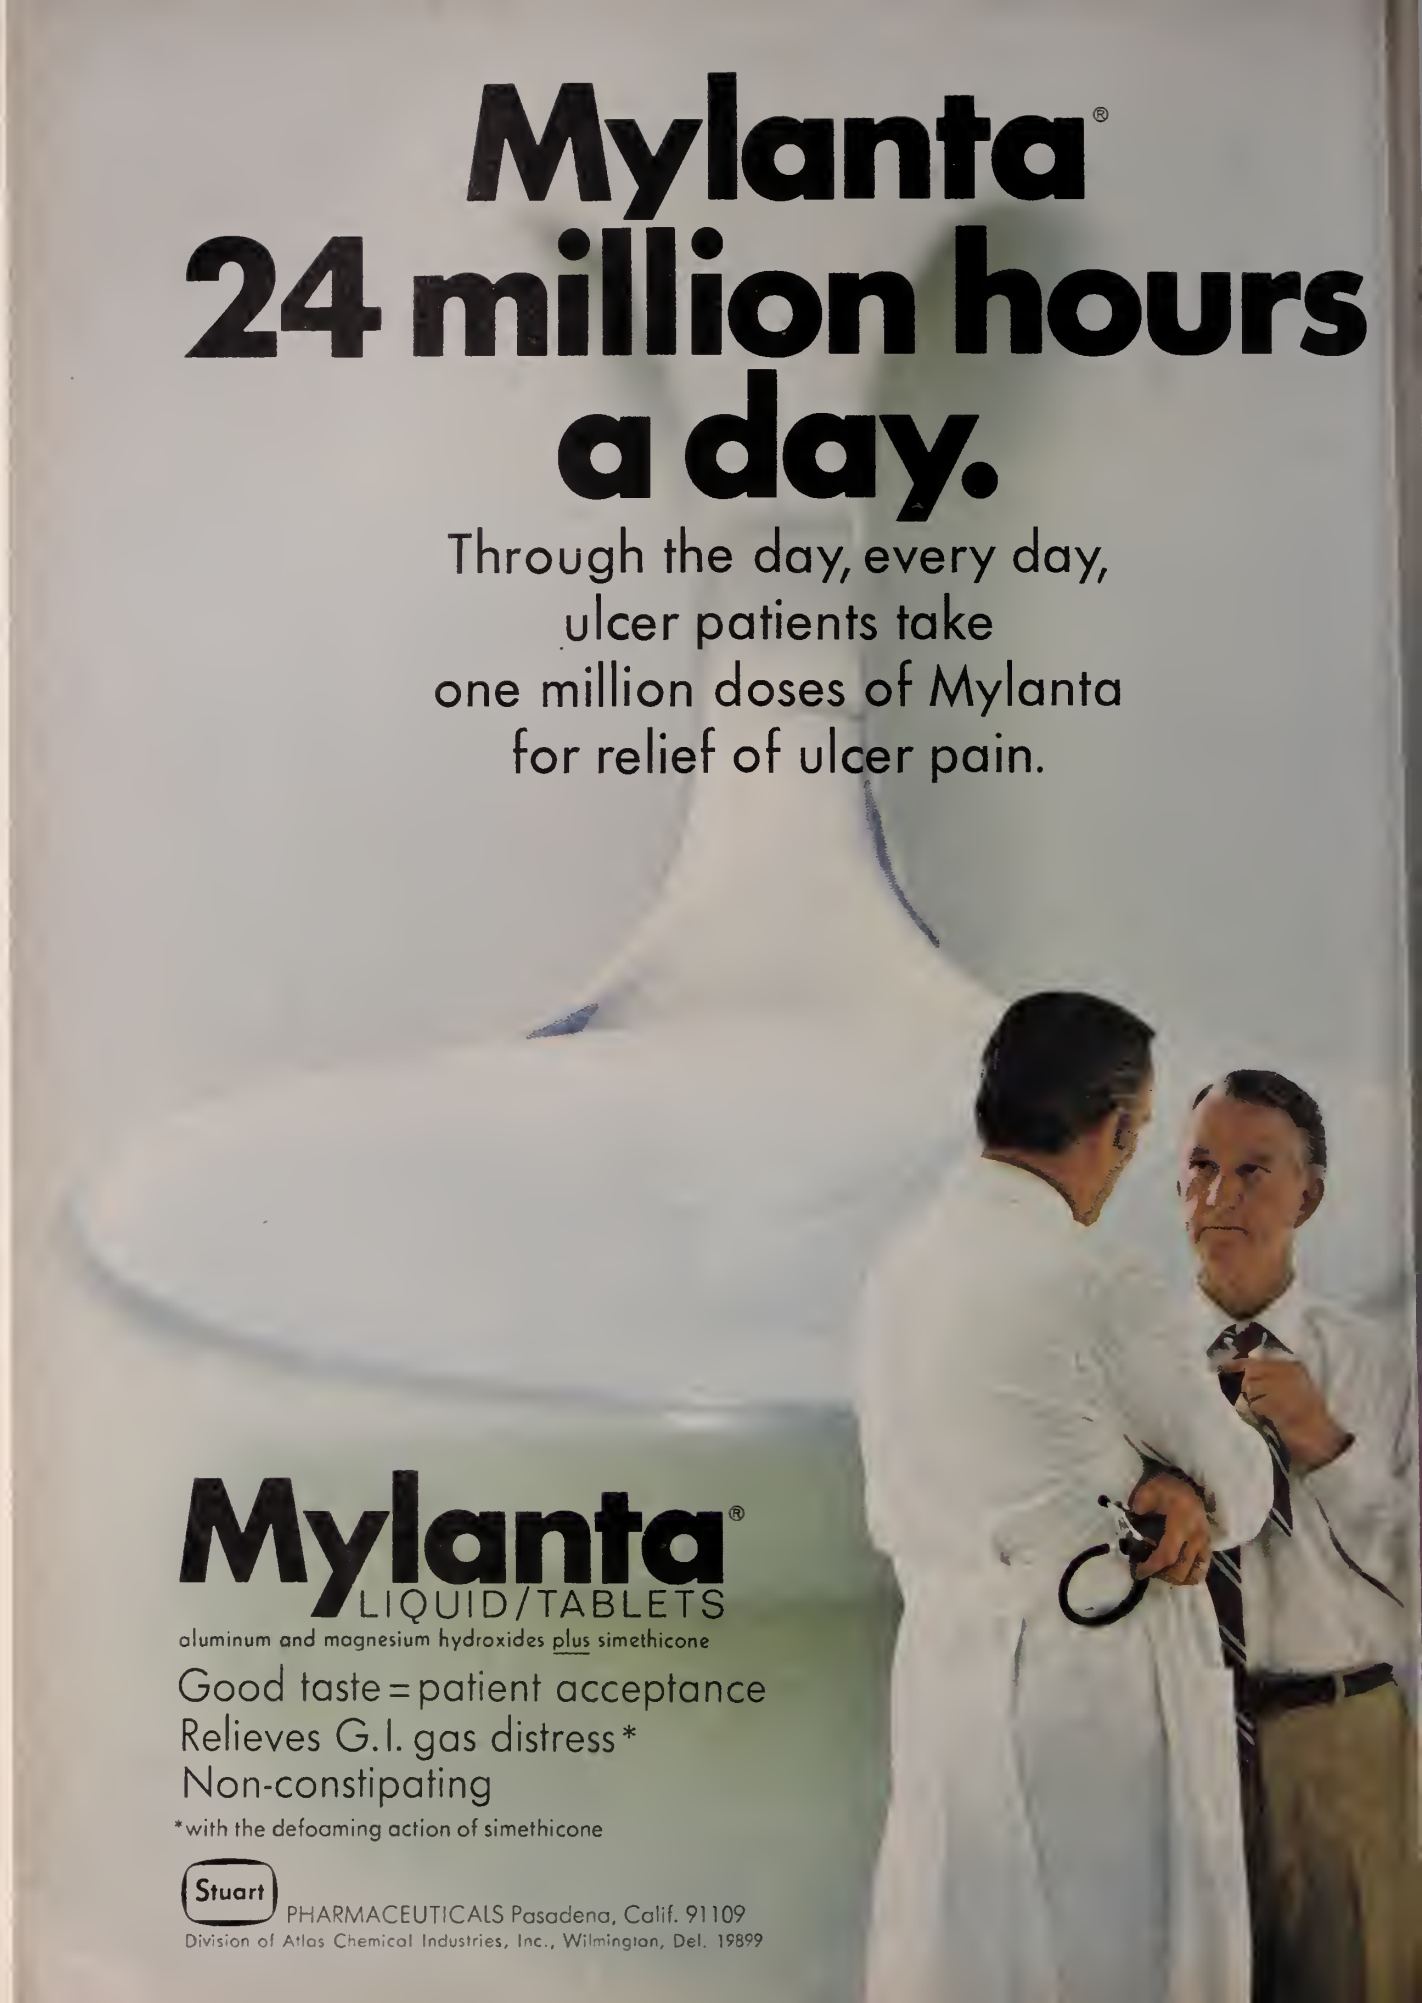
Supplied: Bottles of 50 capsules.

SK&F *Smith Kline & French Laboratories*

Trademark

ORNADE® SPANSULE®

brand of sustained release capsules



Each capsule contains 8 mg. of Teldrin®(brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; 2.5 mg. of isopropamide, as the iodide.

UNCOMMON RELIEF FOR COLD SYMPTOMS

OR-203

Mylanta®
24 million hours a day.

Through the day, every day,
ulcer patients take
one million doses of Mylanta
for relief of ulcer pain.

Mylanta®
LIQUID/TABLETS

History

The Story of The Childrens Hospital

ROBERT ROSENTHAL, M.D.*

INSTITUTIONS FOR THE CARE of children first took the form of foundling homes or hospitals during the early Middle Ages, even though always throughout the ages there have been parents who were either unable to care for their offspring or who were ashamed to acknowledge their paternity for fear of social criticism, and, in some cases, of ostracism from society. Foundling institutions, born out of compassion and pity for helpless waifs, appeared throughout Europe and in the Middle East. Unfortunately, these children's homes acquired poor reputations, because of the incredibly high mortality rate among their inmates. It is said, perhaps in a grimly jocular vein, although with enough truth, that in one year in a single home the death rate was 107 percent! The explanation of this astonishing figure is that not only did all the children admitted in one year die, but also seven percent of the children admitted the previous year. No better evidence could be put forth to underscore both the lack of proper general care and the lack of even elementary medical treatment in these early institutions.

Dispensaries

We might ascribe the beginning of the movement leading to the development of children's hospitals to dispensaries for children. The first of these was George Armstrong's Dispensary for the Poor Infants, opened in London in 1796. His service, because of lack of funds, continued for only a few years, but the idea grew. Eight years later, the first such dispensary was organized in Vienna, Austria. The history of children's hospitals, it will be seen, is not as long as sometimes thought. Yet, throughout the eighteenth century, there were no children's hospitals as such. Children, needing hospitalization, were placed in regular hospitals which were frequently so overcrowded that the children were placed either in beds with adults or in beds with several other children.

*St. Paul, Minnesota.
This paper was submitted in September, 1971.

Children's Hospitals

Overcrowding was such a problem in Paris at the *Hotel Dieu* that it prompted some forward-looking individuals to organize the first hospital solely for children. This was the *Hõpital des Enfants Malades,* established in 1802 by reorganizing an orphanage for girls, the *Maison de l'enfant Jésus,* into a three-hundred-bed hospital to care for children between the ages of one and one-half years and 15 years. Children, transferred from other institutions, rapidly filled the new hospital. A serious attempt was made to reject youngsters suffering from obviously contagious diseases.[1] For the first time in the history of pediatrics the diseases of children could properly be studied and the results of treatment observed.

Not until 1834 was the second such institution founded, the Nicolai Hospital in St. Petersburg. In 1841, another was opened in Ludwigsburg, Germany. Within the next two decades, two more institutions were established in Russia, and one in Hungary and another in Sweden. Not until 1855 did the movement for special hospitals for children reach the United States. In that year Philadelphia opened the first hospital for children of the poor in this Country, but it provided only 12 beds. During the next decade, hospitals in Chicago, New York, and Boston were founded. Seven more such institutions were opened in various cities during the 1870's and four more during the 1880's. Almost every large city enjoyed the benefits of a hospital for children during the first decade of the twentieth century, but there was none in the northern zone from Chicago to the Pacific coast.[2]

The Founding of The Children's Hospital in St. Paul[3]

St. Paul, lay in the neglected northern zone, and the crying need of a children's hospital in Minnesota was noted by Dr. Walter Reeve Ramsey. Ramsey, of Scotch ancestry and born in Canada, studied medicine at the University of

Maryland and was graduated in 1896 from the University of Minnesota medical school. The study of the diseases of children and of their treatment intrigued him early in his professional career, and, although he started in general practice, his interest in pediatrics steadily increased. He soon was placed in charge of the pediatric department of the City and County Hospital in St. Paul. He took postgraduate training in Boston and New York and soon began to teach pediatrics at the University of Minnesota. After further intensive postgraduate studies in Vienna and Berlin, he returned in 1902 and became the first physician to limit his practice to pediatrics in this area. He organized the first Baby Welfare Clinics in 1911 and devoted time to writing books pertaining to infant care, infant feeding, and the nursing care of children. Although his work was interrupted by service abroad during World War I, Ramsey continued to study his specialty. He was especially interested in childhood tuberculosis and visited various tuberculosis clinics, including Rollier's in Switzerland.[4]

With his war service behind him, Ramsey purchased five lots on Pleasant Avenue near St. Luke's Hospital, an ideal site for his proposed hospital. The lots sloped upward and faced south, so that the structure he conceived would be both well supplied with sunlight and equally well protected from north winds. Funds were raised with difficulty and the institution was incorporated by the spring of 1923. However, Ramsey's first hospital was opened, not on the fine spot he had purchased, but in an old, frame building adjacent to and owned by St. Luke's Hospital. Over the entrance he proudly hung a sign "Children's Hospital, Inc." This sixteen-bed institution was governed by a Board of Trustees and was used for four years. St. Luke's Hospital provided all laboratory, xray, and surgical facilities.

Meanwhile, Ramsey saw the cornerstone laid on August 24, 1927 for a children's hospital on the original site he had purchased. On that occasion, Ramsey's old friend, Dr. Issac Abt, of Chicago, delivered the dedicatory address. On July 23, 1928, the three-story building was formally opened to patients. Ramsey held the unpaid position of medical director and the active staff consisted of 15 physicians.

At the first staff meeting held in the basement meeting hall, the initial officers were elected. The members present unanimously elected Dr. James Trent Christison, chief of staff, because he was the oldest member and because he was the first of the group to teach pediatrics at the University of Minnesota. Indeed, Christison taugh pediatrics before Ramsey did, but he did not restrict his practice as early as had Ramsey. Ramsey was not elected chief because of his position as medical director. Christison, somewhat reluctant to accept the chief-of-staff post, said that "at my age" (he was only 63) "I prefer to sit by the fire and read a good book instead of going to a staff meeting." However, he fulfilled the post creditably. In 1944, when almost 79, he suffered a severe hip injury and died shortly thereafter. Christison, like Ramsey, was of Scotch descent, spent his childhood in Canada and was graduated from the medical school of the University of Minnesota.

The Early Years

In 1928, when the Children's Hospital formally opened, seven patients were transferred from the old, frame house at the corner of Smith and Walnut streets. Historically, practically all children's hospitals began primarily as charity hospitals, but the St. Paul institution initiated the policy of permitting patients to pay what they could afford. The minimum rate was $2.50 a day, and 80 percent of the early patients paid this fee. Patients were never designated as charity cases, but as free, part-pay, or full-pay individuals. During the first year, one percent of the patients fell into the free category, three percent

Fig. 1—The orginal hospital, at the corner of Smith and Walnut, St. Paul, Minnesota.

into the part-pay category, and ninety-six percent into the full-pay classification. Ramsey conceived of the hospital serving the "Great Northwest" and during the first nine months of the institution's life, 79 percent of the patients were from St. Paul, 14 percent from Minnesota areas beyond St. Paul, and seven percent from states other than Minnesota. Expenses exceeded income and by the end of the first year of operation there was a deficit of almost $30,000.

The active staff was comprised of all the pediatricians in St. Paul, who in conjunction with other physicians forming the associate and consulting staff, provided excellent service. Those on the consulting staff were required to give free service to free-bed patients. An educational program, in keeping with Ramsey's ideas, was begun during the first year and a school for nurses was begun. A graduate house physician was on duty part of the time, and arrangements were made with the University of Minnesota to accept a "fellow" for postgraduate research work.

An intern program, even though the depression of 1929 made progress difficult, was instituted, but not even the growing economic dislocation prevented an increase of patients. In 1928, 681 patients were admitted, in 1929, 1,316 and in 1930, 1,435. In addition 230 outpatients received attention in 1930. A bi-plane fluoroscope, to aid in the removal of lung foreign bodies and in setting fractures was acquired in 1931, the first of its kind in the Northwest. In that year, the Hospital published a textbook of pediatric nursing based on practices used in the hospital.[5]

Unfortunately, the continuing depression resulted in fewer and fewer paying patients, and every year witnessed a deficit. Admissions dropped to 999 in 1932, which was 436 less than during the previous year. Meanwhile, in a period of 12 months, the average daily cost per patient increased from $4.56 to $5.82, but the average daily income had risen only to $3.45. Some services were curtailed, floors were closed, salaries cut, and fees reduced for laboratory technicians and anesthetists. During 1932-1933, admissions dropped by another 270 patients and the daily income per patient was only $3.00. The monthly operating budget was cut $3,500, and the first and third floors were closed. The salaries of employees receiving full maintenance were reduced by 40 percent and wages of employees living outside of the hospital were slashed from 20 to 30 percent. The nursing school was closed. Despite these economies, the operating deficit was $11,200.

The Hospital Survives the Depression

Gradually, as the national and local economy improved, conditions slowly grew better for the hospital. A fear that the institution might be forced to close gradually gave way to confidence. During 1934 sixty-three more patients were admitted, and by the close of the year the financial situation was improving. This was due in part to the creation of the Junior League of The Children's Hospital Assocation, a group organized to raise funds for free beds.

The School of Nursing was re-opened in 1935; 1,210 patients were admitted, 418 more than in the previous year; 944 more laboratory tests were made; and 247 more major operations were performed. The next year an intern affiliation was instituted with Miller Hospital, and this service was much appreciated by the attending staff. During 1936-37, the third floor was re-opened, and there was an increase in admissions, laboratory work, and surgery. In the years 1937-38, a period when the Minnesota Hospital Service or Blue Cross became a factor in hospital income, 49 percent of the income for hospital services came from sources other than pay patients. The accounting system was changed to the calendar year. During this period The Children's Hospital Association contributed $16,000.

During 1939-40 all hospitals were busy, and many physicians brought patients for the first time to Children's Hospital. Infantile paralysis victims were cared for at Children's Hospital when funds were available, while awaiting care at Gillette Hospital.

World War II Years

The Hospital's annual report for 1942 stated it was "the busiest year in its history and certainly the most turbulent." For one thing, five members of the medical and two of the nursing staffs left to serve in the armed forces. This loss, coupled with the deaths of Dr. Harry P. Ritchie and Dr. George Hagaman, placed additional burdens upon those who remained. Ritchie was noted far beyond the boundaries of Minnesota for his plastic surgery. Hagaman was an excellent pediatrician endowed with great practical knowl-

edge. The year also witnessed the inauguration of the Federal Heart Clinic, under the auspices of the State Department of Public Welfare and directed by Dr. Paul Dwan, University of Minnesota. Patients in this clinic remained in the hospital for long periods of time. Other changes and improvements included the moving of the laboratory to better quarters, the installation of a portable electrocardiograph and the purchase of a portable x-ray unit and a battery-powered light for use in the operating room in the event of a general power failure.

Dr. Yoshio Sako was hired in 1943 as an assistant laboratory technician. He served also as junior intern and in this capacity exhibited such unusually good training that he proved an invaluable addition, especially since it was difficult for Children's Hospital to secure continuous intern coverage from the other St. Paul Hospitals. A better teaching program utilizing free-bed patients was developed, and the number of patients increased considerably. The acquistion of a Leitz colorimeter enabled Children's Hospital to make laboratory tests which previously were done at Miller Hospital.

The Hospital Grows

During 1945, a period of change and expansion, the Children's Hospital became affiliated with the University of Minnesota with Ramsey securing $1,200 annually for such a relationship. The staff numbered 14 pediatricians, nine surgeons, four orthopedists, 13 eye-ear-nose and throat specialists and one pathologist. Mr. Harold Bend, a year earlier, had equipped the large operating room as a memorial to his wife. A fourth floor, somewhat smaller than the original ones, was added because of increasing demand for beds, and the daily average census almost immediately increased by 14%. Supplies, now that the war was over, became both more plentiful and more costly. In the five years between 1940 and 1945, the price for hospital supplies rose 40 percent with yet another increase of 20 percent the following year. Two interns instead of one were obtained from Miller Hospital and the University of Minnesota furnished both a rotating resident and intern each quarter. The yearly admissions passed the 2,000 mark.

Miss Eleanor Sackett, assistant superintendent, became director in August, 1947, a post she held until 1970. During those years of decisive developments, her gift of organization and her equally important quality of tact promoted harmony among the staff, residents, interns, personnel, and the board. Yet she faced serious problems. It was necessary, for example, in 1948 to close the second floor because of a shortage of trained nurses. She played a prominent role in plans for expansion. She interested herself in a newly organized volunteer play-lady program. With the annual payroll increasing to 65.5 % of the total hospital expenses, it became necessary to steadily increase the cost of rooms.

The year 1952 marked the tenth anniversary of the beginning of the Federal Heart Program. The hospital cared for about 50 patients annually in the program. The average length of stay of patients in this program had been reduced from 87 to 25 days. During 1953, as the result of a survey by hospital experts, an expansion program was begun. A campaign to raise $2,250,000 was begun. The surgical suite, financed by The Children's Hospital Association, was remodeled. An anesthesiology department, headed by Dr. Ellis N. Cohen, was formed and resulted in a major improvement in the hospital's surgical

Fig. 2—Eleanor M. Sackett, administrator from 1947-1970.

performance. Because of lack of state funds, the Federal Rheumatic Clinic was discontinued in 1955.

The Enlarged Hospital

On July 22, 1957, ground-breaking ceremonies for the first phase of the new addition took place, but this was not the only significant event in the history of the institution. Ramsey had retired as medical director. Interns now rotated monthly, coming from the University of Minnesota and local hospitals. St. Luke's Hospital furnished a two-year resident, and, shortly thereafter, another came from Midway Hospital. By September, 1959, the new addition had been completed and all patients transferred to it. The East Wing was remodeled, and the Peter Pan Coffee and Gift Shop opened. The new addition was named "Lang Wing" to honor Mrs. William Lang, who, through the years, devoted so generously of her energies to the institution. The completion of the building project was celebrated on April 30 and May 1, 1960 with an open house. The old wing, now remodeled, was called the "Ramsey Wing." It included a communicable disease unit, so that, for the first time, the by-laws of the hospital could be altered to permit *any* patient, without exception, to be admitted regardless of his medical condition.

Although the new wing and changes in the older parts of the building greatly increased the total amount of space, they did not add greatly to the hospital's capacity for care of more patients. Indeed, room was provided for only 25-30 percent more patients. New space was devoted to the x-ray department, the laboratory, the out-patient department, the library, the dining room and administrative offices. A general feeling prevailed that the Hospital was at the "threshold of planning new services for health care for children in our community."

This proved to be true, for the institution during the 1960's did forge ahead. An Intern Education Coordination Program, under the supervision of Dr. Martha Burke-Strickland, was developed with the result that interns were given better learning experiences and patients received closer supervision. The program permitted the admission of more critically-ill children, especially newborns with respiratory difficulties. As a result of Dr. Strickland's excellent teaching instruction and equally fine nursing care the house staff was able to render superior care to critical infants. In 1964, two years after the program started, Dr. Strickland's title was changed from Coordinator of Intern Education to that of Director of Medical Education. The program now drew residents from the Department of Pediatrics of the University of Minnesota and in 1965, two University residents rotated through the Hospital every three months. Plans for Children's Hospital own residency program were made this year and grand rounds and all-day seminars were also instituted.

Peaceful progress was interrupted in 1964 when a dispute developed between the hospital administration and the housekeeping personnel. The latter, in violation of state law, went on strike. The loss of help crippled the institution in several ways and made the task of feeding patients especially difficult. Following a court injuction, most of the workers returned to their jobs. The strike was resolved by arbitration. Not

Fig. 3—The Lang Wing, opened in 1959.

Fig. 4—Eleanor M. Sackett and Dr. Ramsey at the ground breaking ceremony in 1957.

even the strike, however, prevented the hospital from enjoying a successful financial season. Admissions rose to over 4,900.

The increased patient load plus an admirable educational program prompted the institution to gather all its educational functions under the jurisdiction of a single Education and Research Committee, which was to be responsible for the scientific programs for staff meetings, special lectures, and seminars. The hospitals own residency program was approved, and the appointment of a surgical resident, affiliated with Miller Hospital, was effected. With the expansion of its intensive program in medical education, Children's Hospital was well on its way towards becoming a center for pediatric research, a function which Ramsey had envisioned from the beginning. More and more children were being referred to the Hospital for difficut diagnostic problems and intensive care. The residency program was further strengthened, and the first Children's Hospital resident began his training July 1, 1966. At the same time, a new medical student clerkship training program and a program in intensive care for nurses were initiated. An intensive care unit for newborns, a unique service in midwestern states, began operating in 1967. Dr. Krishna M. Saxena joined the staff as Associate Director af Medical Education, and he encouraged members of the pediatrics department of the University of Minnesota to come to Children's Hospital for conferences and rounds. Thus, the relationship between the hospital and the University became closer.

The Children's Hospital Clinic was officially opened on January 3, 1968, replacing the pediatric department of the St. Paul Medical Center, which had closed at the end of 1967. The clinic's transition was accomplished without any lapse of service and the new clinic continued to play a vital role in the training of house staff. During the first year of the clinic there were 5,146 visits by the 250 families covered by the comprehensive health program. Dr. Strickland resigned during the year, after serving half a decade, and Dr. Saxena succeeded her as Director of Medical Education. Admissions, during 1968, numbered over 4,000 and days of patient care totaled 28,900.

The year 1969 offered an excellent vantage point for retrospect and summation of progress made during the decade. The completion of the

Fig. 5—Ward A. Stoddard, Administrator of The Childrens Hospital.

Lang Wing inspired a new era of specialized care; the expanded facilities of the x-ray department and laboratory provided new diagnostic techniques; the intensive care unit for newborn infants rendered a unique service in the area; increased library holdings, the appointment of a full-time librarian and the revamped dietary department, were models of planning and efficiency; the closer relationship of the hospital with the pediatric department of the University of Minnesota brought mutual benefits; and the approval for the hospital's own residency program was a great forward stride.

A new addition to the hospital, begun in July, 1969, was completed early in 1970. Although the additional space which the addition provided will not solve the institution's future needs, it does permit the hospital to presently function more efficiently and effectively. That the institution is growing is evidenced by the following 1969 statistics: over 4,000 inpatients and almost 7,300 outpatients; 5,600 clinic visits; 610 major operations and 389 transfusions. On January 4, 1971, Ward A. Stoddard became administrator.

The Childrens Hospital may well be proud of its growth and accomplishments during the forty-two years since it first opened its doors. Of the original pediatric staff, three continue to be active, one is connected with the Faribault School for Retarded Children, two have moved from St. Paul, one has retired, and the others have passed away. Dr. Ramsey, who, at ninety-nine years, remains in good health, is mentally keen, and watches with utmost interest the fulfillment of his dream of long ago.

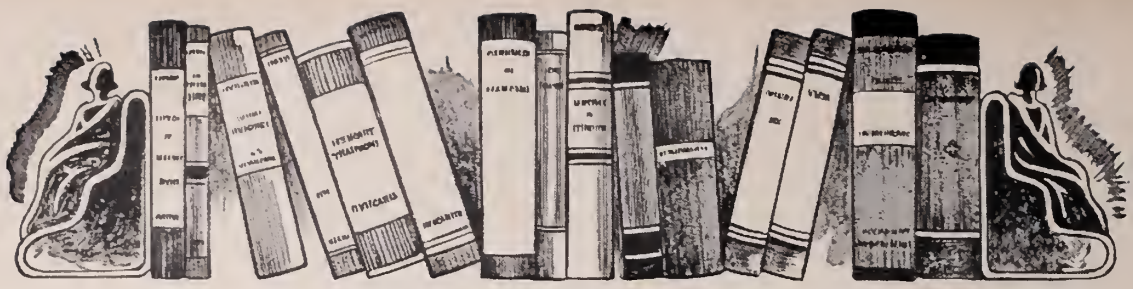
Doctor Francisco Grande Awarded First Spanish Prize

Dr. Francisco Grande, Director of the Jay Phillips Research Laboratory at Mount Sinai and Professor of Physiology at the University of Minnesota Medical School, has been awarded the Rodriguez Pascual Prize for medical research.



Awarded for the first time, this prize has been recently instituted by the Spanish philanthropist, Eugenio R. Pas, Marquis de Pelao. It is given to Dr. Grande "in recognition of his contributions to medical knowledge throughout a lifetime devoted to research in the basic sciences of medicine."

The prize was given to Dr. Grande in a ceremony taking place in the College of San Carlos, a building of the Madrid University Medical School, January 24, 1972. At that time Dr. Grande lectured on "Hormonal Control of Fatty Acid Mobilization," describing his work currently involved at the Jay Phillips Research Laboratory at Mount Sinai.

Born in Colunga, Spain, Dr. Grande graduated summa cum laude from the Madrid University Medical School with his doctorate of medicine. Various working positions in physiological laboratories in Spain, German, Denmark and Wales brought Dr. Grande in contact with the world's outstanding researchers in physiology.

The amount of the prize is two million pesetas, about $30,000.

For the cause that lacks assistance,
The wrong that needs resistance,
For the future in the distance,
And the good that I can do.—George Linnaeus Banks

Book Reviews

HANDBOOK OF LEGAL MEDICINE by Helen R. Morritz, M.D.; C. V. Mosby Co., 1970; Price: $8.75; Pages: 238.

For the physician who ordinarily is not well versed in the legalities of medicine, his conduct in court, his privileges and responsibilities under the circumstances of expert testimony, this Handbook is an excellent source of reference.

The first part deals with scientific, medical, legal investigation, and the second part deals with the physician, the patient and the law. In the second part the medical legal liability of the physician in relation to his patient is adequately dealt with.

There are about 16 human interest sketches depicting most of the commonly encountered medical-legal problems of which physicians are aware: criticism of another physician, the importance of reliable laboratory diagnostic aid, avoiding a delay in diagnosis, guaranteeing a cure, the need for xrays in bone injury, and other problems that are commonly discussed in the staff room, so that the answers are usually known.

The book is nicely edited and well bound. Page headings might have been of additional value for thumbing purposes.

Carl O. Rice, M.D.

INSTRUCTIONAL COURSE IN LECTURES; C. V. Mosby Co.; Price: $19.50.

The series of manuscripts in this volume are by a group of authors, all of whom are well qualified to deal with the problem that they have chosen. Each of the 13 topics is significant to the practicing physician who deals with injuries or orthopedic diseases. They constitute, on the whole, the most commonly encountered problems and should be constantly in the mind of the clinician.

Adequate but not exhaustive bibliographic references are included. The volume is well bound and beautifully illustrated.

Carl O. Rice, M.D.
Minneapolis, Minnesota

BIG FLEAS HAVE LITTLE FLEAS by Robert Hegner; Dover Publications, Inc., New York; $2.00.

This is a fascinating book with cartoon illustrations loaded with information and facts about the protozoa. It was almost shocking to read that every organ and every tissue in our body may be so well parasitized with protozoa that were our body "to disappear entirely, leaving behind only the parasites, a perfect outline of the human form would remain, and even the features would be so clearly discernible that individuals could be recognized."

I recommend it for an hour of intellectual and fascinating reading.

Carl O. Rice, M.D.
Minneapolis, Minnesota

RENAL DISEASE IN CHILDHOOD by John A. James, M.B., M.R.C.P., D.C.H.; C. V. Mosby Company, St. Louis; Publication date: 1968; Price: $18.50.

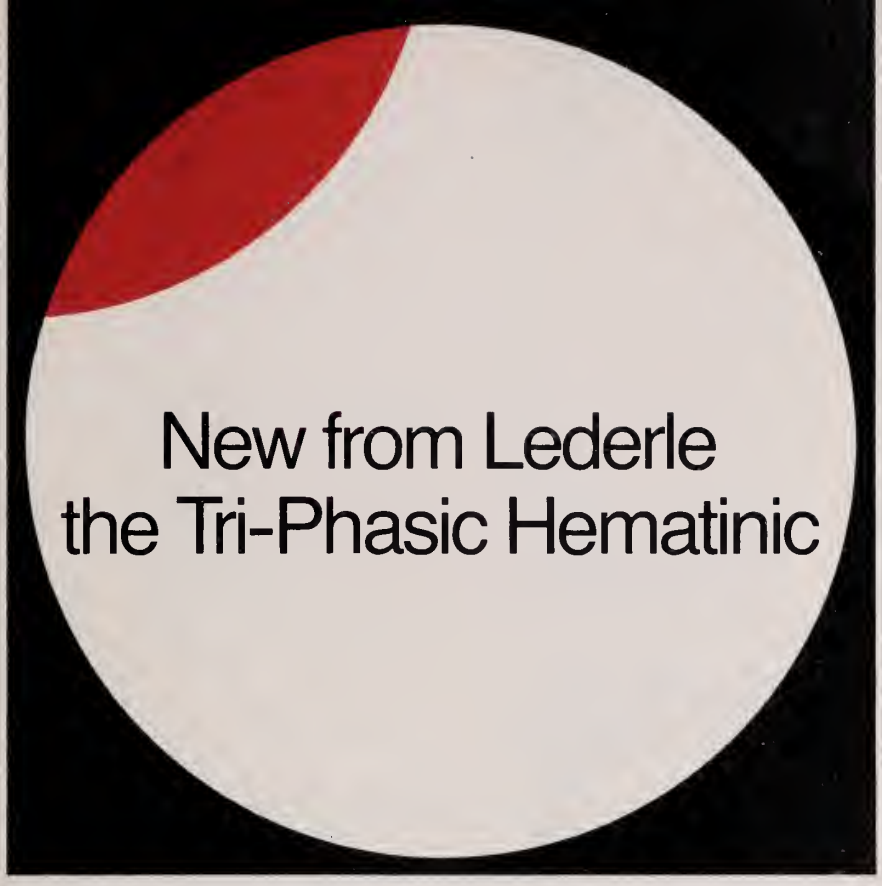
An excellent book, concise and practical, with special emphasis on diagnosis and treatment of renal diseases in children. As such it will be particularly useful to physicians in training and practice who care for renal diseases in children as part of a larger group of patient problems. Discussions of etiology and pathology are brief and adequate. Choice and selected references are appended to each chapter for physicians who become interested and desire further information.

The final chapter on dialysis and homotransplantation offers steps from the practical into the highly technical, controversial, and rapidly changing areas of research and therapy. This chapter seems a forced after-thought in a practical book since both of these subjects might well have been handled in the discussion at the end of the chapter on renal failure. However, this is a minor defect, for the first fourteen chapters of the book are excellent and justify wide acceptance of this book by its intended audience.

Warren J. Warwick, M.D.
Minneapolis, Minnesota

SYNOPSIS OF DERMATOLOGY; Wm. D. Stewart, M.D.; Julius L. Danto, MD; and Stuart Maddin, M.D.; The C. V. Mosley Company; Price: $13.85.

This second edition of Synopsis of Dermatology is an excellent book for both students and practitioners. The text is divided into four sections. The first deals with the development, structure, and function of the skin. Second, the office practice of dermatology is discussed. Regional diagnosis is next covered; while the final section describes individual diseases.



Discussions of the various dermatologic conditions are by necessity short in a book of this length (pp 445). However, the descriptions are adequate and well written. In addition, many of the newer concepts in both diagnosis and treatment of dermatologic disease are covered. For each disease, the authors, include a clinical description, differential diagnosis, and treatment. It should be noted that this book is well illustrated with many color plates, most of which are of excellent quality. This volume should be of value for those interested in clinical dermatology.

Willard Peterson, M.D.
Minneapolis, Minnesota

CURRENT DERMATOLOGIC MANAGEMENT by Stuart Maddin, M.D.; C. V. Mosby Co., St. Louis, Mo., 1970; Price: $38.75; Pages: 330.

This is an excellent book, not only for the dermatologist, who is surely aware of all of these diseases and recognizes them, but for any physician who is in practice and is interested in identifying skin diseases that may have to be referred.

Carl O. Rice, M.D.
Minneapolis, Minnesota

Specifically formulated with
vitamins and minerals important
in the treatment of anemia

PHASE 1
Enhanced Absorption

Each tablet provides 115 mg elemental iron as the highly absorbable ferrous fumarate *plus* 600 mg of Vitamin C.

PHASE 2
Erythrocyte Formation

Each tablet provides Vitamin B_{12} (25 mcg) and Folic Acid (1 mg) to replace deficiencies.

PHASE 3
Premature Hemolysis

Each tablet provides Vitamin E, which may be involved in lessening red blood cell fragility.

For common anemias
as well as problem ones

TriHEMIC™ 600
HEMATINIC TABLETS

Tri-Phasic Hematinic with 600 mg Vitamin C PLUS Vitamin E

Each tablet contains:	
Vitamin C (Ascorbic Acid)	600 mg.
Vitamin B_{12} (Cobalamin Concentrate, N.F.)	25 mcg.
Intrinsic Factor Concentrate	75 mg.
Folic Acid	1 mg.
Vitamin E (*d*-Alpha Tocopheryl Acid Succinate)	30 Int. Units
Elemental Iron (as present in 350 mg. of Ferrous Fumarate)	115 mg.
Dioctyl Sodium Sulfosuccinate U.S.P.	50 mg.

Dosage: One Tablet Daily.
Available in Bottles of 30 Tablets.
On Your Prescription Only.

Precautions: Some patients affected with pernicious anemia may not respond to orally administered Vitamin B_{12} with intrinsic factor concentrate and there is no known way to predict which patients will respond or which patients may cease to respond. Periodic examinations and laboratory studies of pernicious anemia patients are essential and recommended. If any symptoms of intolerance occur, discontinue drug temporarily or permanently. Folic acid, especially in doses above 1 mg. daily, may obscure pernicious anemia, in that hematologic remission may occur while neurological manifestations remain progressive.

Adverse Reactions: G.I.: nausea, vomiting, diarrhea, abdominal pain. Skin rashes may occur. Such reactions may necessitate temporary or permanent changes in dosage or usage. Allergic sensitization has been reported following both oral and parenteral administration of folic acid.

TriHEMIC™ 600
HEMATINIC TABLETS

Tri-Phasic Hematinic with 600 mg Vitamin C PLUS Vitamin E

Specifically formulated with vitamins and minerals important in the treatment of anemias, plus a stool softener to counteract the constipating effects of iron.

Diet and Diabetes

A New Approach to Planning Meals

GARIFALLIA MILLER, R.D.*

IN LOOKING CAREFULLY at today's management of diabetes, three facts emerge:

(1) That up to the present time no hypoglycemic agent has been developed that can synchronize its activity with blood sugar levels. Consequently, diet still remains an important factor in the treatment of diabetes. Doctors may disagree as to the goals the treatment should seek to achieve. Nevertheless, they all recognize that freedom from frequent annoying complications depends on some kind of regularity of feeding.

(2) The second fact is that except for the hospitalized diabetic, treatment and control is the individual diabetic's responsibility even from an early age. Diabetics, therefore, must know how to plan their meals themeselves.

(3) The emotional state of the individual affects his control. Most diabetics do well and are resigned to the necessities of injecting insulin and testing their urine. However a great many of them have difficulties adhering to any kind of a meal pattern. The teenagers especially are resistant to accepting any regimentation even though they may be aware of future consequences. Diets as a rule are too regimented, extremely monotonous and inconvenient. In most cases they demand too much from the patient and result in temptations, stresses, worries, periods of depression and guilt feelings.

The new method for planning meals, the *Guide To Meal Planning* was developed in an attempt to eliminate some of these frustrations. Our objectives were to make meal planning:

(1) Simple enough so that it becomes as automatic as getting dressed. Since it is the individual diabetic's responsibility to plan his meals, we felt that the simpler the method of determining the quantities of food and the ratio of protein, carbohydrate and fat in a meal, the easier it would be to remember and to follow.

(2) Flexible enough so that it would be easily adjustable to all situations. Years ago, temptations to eat forbidden foods were very few; however, nowadays our social life and advertising media make it quite difficult to avoid temptations. For children this is even more difficult. The diabetic should be taught how to incorporate some regular desserts in his diet, not only the so-called dietetic ones. We believe that a piece of regular cake, poorly substituted, is not as dangerous to the diabetic's control as the frustration of not eating it, or the sense of guilt after eating it in spite of its exclusion from the diet. It is very significant that up until we started showing how to incorporate some regular desserts in the diet patterns, diabetics would never admit they used them. Now it is a different story entirely.

The new method, the *Guide To Meal Planning,* is a simplification of the *Exchange Lists* method.

Exchange Method

In the last twenty years diabetics were taught to plan their meals with the *Exchange Lists* method. We found that diabetics, regardless of age, intelligence, or educational background had many difficulties with the exchange method. The word *exchange,* for instance, is very confusing. There are too many groups and too many measurements to represent one unit of food or one serving. This requires a great deal of memorizing, one more cause of resentment, and sooner or later the method is forgotten.

The "Guide To Meal Planning"

The first step for the simplification of the *Exchange Lists* method was to find another word to represent a unit of food that would be familiar and, therefore, easily accepted and remembered. The word *serving* was chosen. Secondly, we named groups of foods on the basis of composition. For instance, the meat group was called *protein foods,* the bread group was called *starchy foods.* Thirdly, we eliminated many measurements. A diabetic is now taught only three

*Director of Dietetics and Nutrition, The Childrens Hospital, St. Paul.

measurements, each to represent one serving or one unit of food. Fourth, except for three vegetables included in the starchy group, foods were listed in groups in the way people know them: proteins, milk, starches, fruits, fats, vegetables.

Description of the New Method

Based on their nutritive value, foods are listed in six groups.

Group 1—Protein Foods

In this group we have listed all foods high in protein, and it included:

(1) All meats. (2) All fish and seafoods, (3) Eggs and (4) Cheese.

We use the word *protein* to name this group because the word is well-known even among children, and because it is a word denoting composition and value of food rather than naming one particular food. For a unit of food, or one serving of protein food as it is called in this method, we use a slice of meat or fish, 2 x 3 x ¼ inch. This measurement is also identified on the palm of the individual's hand by tracing a rectangular figure approximately two by three inches.

Group 2—Starchy Foods

All foods high in complex carbohydrates are listed in this group and include:

(1) All flour products: (a) bread, (b) cereals and (c) macaroni, noodles, and so forth. (2) rice and rice products. (3) Three vegetables: (a) potatoes, (b) corn and (c) dry vegetables, legumes. (Carbohydrate content of these vegetables is the same as in all other foods listed in this group.) We named the group *starchy foods* because the word denotes composition. For a unit of food, or one serving of starchy food, we use one half cup.

Group 3—Fruits

All fruits are listed in this group. One serving of fruit is one half cup.

Group 4—Milk

Milk is listed separately. One half cup is used to identify one serving of milk. Greater amounts of milk allowed are identified as two, three or four servings. Depending on caloric allowances, individual preferences and modifications of one's diet, the type of milk an individual should have is marked as skim, 2% or 3½% butter fat.

Group 5—Fat

Butter, margarine, oils and salad dressings are listed in this group. For one serving of fat we use one teaspoon.

Group 6—Vegetables

All vegetables with the exception of the three listed with the starchy foods are included in this group. Listing vegetables into *A and B groups* in the *Exchange* method proved to be somewhat inaccurate. On the other hand, the higher carbohydrate content of a few *B vegetables* when these vegetables are used as *Free Foods* does not alter total average intake. Consequently, we felt there was no need to list the vegetables into two groups. All vegetables are listed in one group, and patients are instructed to use them in any amount—*Free Foods.*

The diabetic learns from this method:

(1) What is included in the group of protein foods.

(2) What is listed in the group of starchy foods.

(3) The three measurements: For proteins, a 2 x 3 x ¼ inch piece, one teaspoon for a fat serving, and one half cup for all other foods. This is all. The average protein, fat and carbohydrate content of a serving of food listed in each group is given in Table 2. The dietitian calculates the diet. The number of servings of proteins, starchy foods, etc. for each meal and snack are written in the space provided on the "Guide To Meal Planning" folder which we provide.

Besides this folder, a small billfold size card is given to the diabetic with this information on it (Table 1). In planning or choosing his meals,

TABLE 1
Billfold Size Card with Food Allowances for Each Meal
Daily Food Allowance

Breakfast:		**Midmorning Snack:**
Protein Food	1	
Starchy Food	2	
Fat	2	
Fruit	1	
Milk	1	2
Lunch:		**Midafternoon Snack:**
Protein Food	1	
Starchy Food	2	1
Fat	2	
Vegetable Any amount		
Fruit	1	
Milk	2	1
Supper:		**Evening Snack:**
Protein Food	2	1
Starchy Food	2	1
Fat	2	1
Vegetable Any amount		
Fruit	1	
Milk	2	1

the diabetic knows or refers to this card for the number of protein or starchy servings, etc., he is allowed at each meal and snack. This way he can easily detect shortages or excesses and make adjustments before serious consequences appear. Also, he can easily make reasonable changes in the basic meal plan to fit special daily demands.

Rationale

Our effort to make meal planning simple was definitely not at the expense of being within the range of safety for "good control." No method has been devised yet that could be used in planning accurately the food intake. For instance: A closer look at the "Exchange Lists" would reveal many discrepancies.

Here are two examples:

	Content		
	Cho	*Pro.*	*Fat*
½ cup noodles = 1 bread exchange	18.6 gms.	3.2 gms.	1.2 gms.
½ cup corn	16.4 gms.	2.1 gms.	0.6 gms.
Yet less corn (⅓ cup) is allowed for	one bread exchange		
½ cup wax beans	5.2 gms.	1.4 gms.	0.3 gms.
½ cup carrots	5.0 gms.	0.6 gms.	0.2 gms.

TABLE 3

	Actual Average Values of Foods in a Group				Food Values given to Groups		
	No. of Items Used	Pro.	Fat	Cho	Pro.	Fat	Cho
Fats	7	0	3.1	0.2	0	4	0
Fruits	33	0.7	0.2	12.6	0	0	15
Fruit-Juice	9	0.4	0.1	16.2	0	0	15
Milk—Whole	....	4.2	4.2	5.8	4	4	6
Starchy-Foods	26	2.3	1.0	14.9	2	0	15
Proteins	29	8.0	4.1	0.2	8	4	0
Vegetables	25	1.3	0.1	4.8	FREE FOODS		

However beans, although similar in CHO content to carrots, are listed in the A group of vegetables. The question then arises, why is it necessary to have patients memorize the different measurements or what vegetables belong to A group or B group? But let us examine another point. Depending on the cut of meat or the type of animal, in 100 gms. of meat, there is a variation of 10 gms. in the protein content to use just two examples. In a half cup of orange juice there is a variation of 5 gms. or more in the carbohydrate content. Furthermore, food manufacturers often alter food composition to the extent that many well established food tables are obsolete. For instance, meat may be injected with a starch product to hold in meat juices during cooking, yet is meat known to be a source of carbohydrate?

With this in mind the following question might be in order. Could we possibly expect and is it at all realistic to have patients memorize or refer to long lists and dozen of measurements in planning their meals? Food tables are good reference material, but one should know their limitations. Whenever an accurate food intake is necessary, a synthetic diet can be prepared. For the rest of the patients, a few general groups of foods and the minimum number of measurements should be quite satisfactory.

Flexibility

The *Guide To Meal Planning* is a tool that can be used in several ways and for many purposes. It can be used for weight reduction diets or normal nutrition education. The practitioner can use all or part of it. Modifications of the type or quantities of fat, cholesterol or sodium, can be marked on the booklet. Also a basic outline of diets with different caloric levels to meet individual philosophies of CHO, fat and protein ratio could be written and used as a guide.

Clear and Full Liquid Modifications

For a full liquid diet, patients are instructed to substitute protein servings with milk servings and starchy servings with fruit juices or pop on a one to one basis. For a clear liquid diet, 1 serving of protein or milk is replaced by half a serving of fruit juice.

Two Year Evaluation

The *Guide To Meal Planning* has been in use for over two years. In our hospital we instruct both parents and children, and thus we are able to evaluate its acceptance by both groups.

In evaluating the method we have the following to report:

1. It is a method simple and easy to teach.
2. Patients and parents understand and remember the method well.
3. Adjustments to the basic meal pattern are made easily.
4. Urine tests showed the same or better results after the change to the New Method. We have no patients reporting either worse urine tests or dissatisfaction.
5. Parents who changed to this method, reported that relationships with their children improved considerably.

6. Last, parents and patients reported a feeling of confidence and security in knowing how to plan meals easily and quickly. For the new diabetic this is of paramount importance.

Summary

The difficulty patients had in understanding the "Exchange Lists" method, the discrepancies in the average values of available glucose of foods within a group, as well as a closer examination of the limitations of food tables led to the development of a new, simpler and more realistic method. *The Guide To Meal Planning,* a general guide with only the basic foods included, was developed.

Nursing

The Nurse and Hospital Emergencies

LOIS ANITA YOUNG, R.N.*

A NURSE WALKS into Room 206 to check her patient. The child is cyanotic and has stopped breathing. Immediately she calls for help and initiates emergency measures. Meanwhile, other personnel assigned to this nursing unit notify the switchboard operator by dialing 414, the hospital emergency telephone number. The emergency cart is brought to the patient's room.

The switchboard operator, on receiving the call, immediately broadcasts "Intern, Second Floor." To assigned medical and nursing staff this means "Report immediately to the second floor nursing unit. There is an emergency."

This is the emergency procedure used at The Childrens Hospital, Inc., Saint Paul, Minnesota.

Emergency carts placed in the treatment room of our nursing units and outpatient department have been found to be most helpful in managing emergency problems. A chrome lake-side cart with easy movable rollers has been adapted to contain the supplies, medications and equipment needed in an emergency. The easy visability and accessability from all sides and the placement of some of the items on small trays are all special features to aid the staff.

The first shelf contains a small tray with the laryngoscope, laryngoscope blades #0-#4, resuscitubes and airways; the suction, oxygen and feeding tubes are in clearly labeled packages. The syringes and needles are in a box beside a sealed plastic drug box. Some of the drugs are placed in styrofoam; labels up for easy reading. Another small tray contains the supplies needed for I.V. therapy. I.V. solutions stocked are: 5% dextrose in 0.33% saline—5% dextrose in 0.45% saline—5% dextrose in water.

Attached to the first shelf is a drawer divided into 16 compartments, which contain different sized hard and soft endotracheal tubes, batteries, laryngoscope bulbs and tracheotomy needles. To aid the staff in finding the necessary endotracheal tubes quickly, the labels are placed at the top of each compartment.

*Director, Inservice Education, The Childrens Hospital, St. Paul, Minnesota.

The second shelf contains supplies needed for intravenous and blood therapy. The spinal manometer is alongside the spinal tap equipment, which has four spinal needles taped to the top of the box. An adapter is attached to the rectal tube ready for use.

The third shelf contains a large and small cardiac board, the Hope and the Ambu resuscitator with infant, child and adult masks, and two clipboards. One clipboard has pre-prepared medication labels (Example: Soda bicarb—dilantin), and the other clipboard has a resuscitation record for recording emergency events.

Special Courses

Besides a better equipped emergency cart, an indepth course titled, "The Role of the Nurse in An Emergency" for R.N.'s and L.P.N.'s has been developed. Full-time and part-time nurses (except Intensive Care and surgery personnel) are regularly scheduled to attend classes conducted by the Inservice Education Staff.

Session 1

The course consisits of a review of methods for reporting emergencies and the emergency code. A taped doctor's lecture titled, "The Role of the Nurse in An Emergency" discusses the signs and symptoms of cardiopulmonary arrest and the responsibilities that nurses may assume to assist at the emergency scene. For example, the role of members of an emergency team are discussed, listing responsibilities as follows:

Nurse 1—Will, on entering the room, place the cardiac board beneath the patient, assist in ventilation and resuscitation, assist in connecting the electrocardiogram instrument.

Nurse 2—Prepares and labels 10cc epinephrine 1-10,-000, 25-30cc sodium bicarbonate and calcium gluconate or chloride 2-3cc. Normal saline is then prepared for intravenous therapy.

Nurse 3—Acts as a record keeper. She charts all pertinent information about the patient. A special resuscitation form was designed to aid in recording when the emergency is over. Nurse 3 will also be responsible for replenishing the emergency cart for future use.

The supervisor, who can assist at the scene of the emergency if needed, is the traffic director, checks baptismal status of patient, talks to the parents, notifies the private physician, if he is not present, and obtains additional supplies and equipment.

The nursing staff has initiated and assumes these re-

sponsibilities now, whenever an emergency occurs.

Session 2

The film "Pulse of Life" or "Prescription of Life" is shown. All nurses practice mouth-to-mouth resuscitation and external cardiac massage.

Session 3

The discussion and demonstration of the emergency cart supplies and equipment has proven to be most helpful to the nurses. This is the "how to," "what to do" and "when to do" session. Many helpful suggestions are made. For example:

(a.) Attaching the laryngoscope blade to the handle is easy and can be done quickly when inserted at a 90° angle, pressed by the thumb and a click is heard, or

(b.) If flashlight batteries are inserted button up, they will make the necessary contact and light up immediately, or

(c.) If you drop the cardiac needle—maybe the spinal needle can be used, or

(d.) How to use the Hope and Ambu resuscitators, or

(e.) How to set up intravenous solution quickly without air bubbles.

It's the "knowing how" and "what to do" that gives the nurse confidence to assist efficiently in an emergency.

Session 4

This session is a discussion of emergency drugs by the hospital pharmacist or inservice instructor.

Session 5

During this session, demonstrations of the cardiac monitor, I.P.P.B. respirator, and oxygen equipment are given by the inhalation therapist.

Session 6

"Listen and Learn."

We allow time for the nurses to discuss problems they have encountered during an emergency situation. They are encouraged to suggest improvements that might help the next time an emergency arises. During one month's classes, thirty-one recommendations for improvements were made. Thirty of these were instituted.

Session 7

Each nurse is given an opportunity to practice in a simulated emergency situation using the emergency cart and Resusci-Anne. An Inservice Education staff member acts as the doctor. The nurses take turns as Nurse 1, 2 and 3.

There are postchecks which aid in determining the effectiveness and success of the course. The nurses, working in teams of two, are required to:

(1.) Practice together two times, by a stated date;

(2.) Report for final evaluation by an Inservice Education staff member or assigned person.

Each assignment is to be completed by a predetermined date. (Appendix D.)

The use of audio-visual aids has helped to strengthen the program. The films "Pulse of Life" and "Prescription of Life" are obtained from the Minnesota Heart Association. The Resusci-Anne and Resusci-Baby manikins were donated to us by the Medical Staff and Board of Trustees. A tape recorder is used to tape all lectures. Our doctors donate many hours of lecture time to nursing education. We are also fortunate to have a demonstration emergency cart to use for all class sessions.

Conclusions

The nurse aides know the location of the emergency carts and have been taught mouth-to-mouth resuscitation. The ward secretaries also know the location and contents of the emergency carts.

We are now planning the use of an emergency resuscitation team in the future. When the emergency telephone number is dialed to notify the switchboard operator of a cardiopulmonary arrest, she will also be given the room number. She will broadcast, "Dr. Blue, Room Number —." Assigned staff, the resident, intern and medical student assigned to the nursing unit, three nurses and a supervisor will respond to the alert.

The concern, interest and assistance of our medical, nursing, and other hospital staff has improved the quality of our emergency program. We will continue to ask for suggestions and ideas from those people who are most involved in the care of patient emergencies.

Had old Hippocrates or Galen,
That to their books put med'cines all in,
But known this secret, they had never
(Of which they will be guilty ever)
Been murderers of so much paper,
Or wasted many a hurtless taper;
No Indian drug had e'er been famed,
Tabacco, sassafras not named;
Ne yet of guacum one small stick, sir,
Nor Raymond Lully's great elixir;
Ne had been known the Danish Gonswart,
*Or Paracelsus, with his long sword.**

---

*Ben Jonson: Volpone, 1607. "Song" (for a quacksalver).

Laboratory Letter

Osmolality

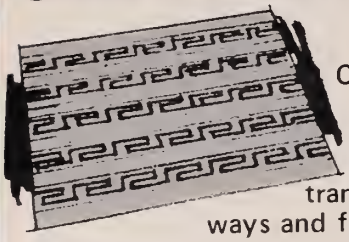
SOME YEARS AGO H. L. Gold wrote a little story about a man who got into trouble with the elves of a certain lake. As punishment the elves decreed that water would actively stay away from him. Since he was at the lake primarily to fish, but wanted also to bathe and drink, the results of the decree proved frustrating to the hero and amusing to the reader.

Now both disease and therapy can alter man's body water, particularly the concentration of elements in it. But unlike the situation of the hero in Gold's story, diagnosing and managing patients with disorders of hydration more often frustrates than amuses. This is true whether one is dealing with the life-threatening hypertonic dehydration of viral enteritis, or the factitious hyponatremia of hyperlipemic states.

Substances dissolved in water exert an osmotic effect. This osmotic effect causes water to move through cell membranes, swelling or shrinking individual cells, increasing or decreasing tissue edema, or even producing hyper- or hypovolemia.

Osmotic pressure can be measured in various ways and with various instruments. At one extreme it can be estimated, which is essentially all we do when we measure serum sodium, while at the other extreme it can be measured directly with a semipermeable membrane, a technique requiring so much sample as to be completely impractical. In practice, we take advantage of the fact that osmotic pressure, boiling point, freezing point, and vapor pressure are tied unalterably together. For example, the more salt one dissolves in water, the higher the osmotic pressure and the lower the freezing point become. Thus, in the clinical laboratory, we can determine the osmotic pressure of a sample of urine or serum by measuring its freezing point.

There are several practical advantages to measuring osmolality by this method. First, it is a quick test with the answer available within minutes after separation of the serum from the clot. Second, it is a non-destructive test and after determination of the freezing point, the sample can be thawed and used for some other determination. Third, it is a "micro" test and utilizes a sample volume of only 0.2 ml, an important consideration in ill infants. Fourth, it is a highly reproducible test. Over the years our pooled, control serum has demonstrated a standard deviation of $\pm$ 2.0 mOsm/Kg.



Osmotic pressure is reported in terms of osmolality (a mole of any substance dissolved in a kilogram of water has the same osmolality—or osmotic effect—as a mole of any other substance). Osmolality is most conveniently reported as milliosmoles per kilogram of water. Normally, serum osmolality is 285 $\pm$ 5 mOsm/Kg of serum water. Urine osmolality varies quite widely, depending on the state of concentration, but is usually in the range of 600 - 1400 mOsm/Kg. The newborn kidney, however, is not capable of concentrating much above 700 mOsm/Kg.

Osmolality is a most valuable screening test for dehydration. If the osmolality is normal, sodium and other solutes are usually normal. An osmolality above 300 mOsm/Kg is indicative of hypertonic dehydration. Serum osmolality is also a useful test for differentiating true hyponatremia from artifactual hyponatremia. The simultaneous determination of osmolality in urine and serum both before and after administration of pitressin is a useful confirmatory test of diabetes insipidus. As a measure of urinary water, osmolal clearance and free water clearance are indicators of antidiuretic hormone activity.

This is only a brief review of a test which can yield more information than its relative speed, and ease of performance might indicate.

COMMERCIAL
CARPET MATTING

Confine trackage and protect entrances, hallways and foyers with decorative carpet mats in beautiful new patterns.

Custom sizes up to 6′ x 10′. Roll stock in 3′, 4′ and 6′ widths cut to your requirements.

We stock carpet mats, rubber matting and fatigue mats. Call us or write for further information and samples.

HEART ATTACK

STROKE

HIGH BLOOD PRESSURE

INBORN HEART DEFECTS

PFIZERPEN® VK
(POTASSIUM PHENOXYMETHYL PENICILLIN)

ACTIONS: *Microbiology:* Phenoxymethyl penicillin exerts high *in vitro* activity against staphylococci (except penicillinase-producing strains), streptococci (groups A, C, G, H, L, and M) and pneumococci. Other organisms sensitive to phenoxymethyl penicillin are *Corynebacterium diphtheriae, Bacillus anthracis, Clostridia, Actinomyces bovis, Streptobacillus moniliformis, Listeria monocytogenes, Leptospira,* and *Neisseria gonorrhoeae. Treponema pallidum* is extremely sensitive. *Pharmacology:* Phenoxymethyl penicillin is more resistant to inactivation by gastric acid than penicillin G. It may be given with meals and average blood levels are two to five times higher than the levels following the same dose of oral penicillin G. Once absorbed, phenoxymethyl penicillin is about 80% bound to serum protein. Tissue levels are highest in the kidneys, with lesser amounts in the liver, skin, and intestines and small amounts in all other body tissues and cerebrospinal fluid. Only about 25% of the dose given is absorbed. In neonates, young infants, and individuals with impaired kidney function, excretion is considerably delayed.

INDICATIONS: Phenoxymethyl penicillin is indicated in the treatment of mild to moderately severe infections caused by penicillin G-sensitive microorganisms that are sensitive to the low serum levels common to this particular dosage form. Therapy should be guided by bacteriological studies (including sensitivity tests) and by clinical response. Culture and sensitivity testing are especially important in suspected staphylococcal infections because increased resistance has been reported. Phenoxymethyl penicillin is not active against penicillinase-producing bacteria.

Note: Severe pneumonia, empyema, bacteremia, pericarditis, meningitis, and arthritis should not be treated with phenoxymethyl penicillin during the acute stage.

Indicated surgical procedures should be performed.

Medical conditions in which oral penicillin therapy is indicated as prophylaxis: For the prevention of recurrence following rheumatic fever and/or chorea. To prevent bacterial endocarditis in patients with congenital and/or rheumatic heart lesions who are to undergo dental procedures or minor upper respiratory tract surgery or instrumentation.

Note: Oral penicillin should not be used as adjunctive prophylaxis for genitourinary instrumentation or surgery, lower intestinal tract surgery, sigmoidoscopy and childbirth.

CONTRAINDICATION: A previous hypersensitivity reaction to any penicillin.

WARNINGS: Serious and occasionally fatal hypersensitivity (anaphylactoid) reactions have been reported in patients on penicillin therapy. While more frequent following parenteral therapy, anaphylaxis has occurred in patients on oral penicillins. These reactions are more apt to occur in individuals with a history of sensitivity to multiple allergens.

Some individuals with a history of penicillin hypersensitivity reactions have experienced severe hypersensitivity reactions from a cephalosporin. Before therapy with a penicillin, careful inquiry should be made concerning previous hypersensitivity reactions to penicillins, cephalosporins, and other allergens. If an allergic reaction occurs, the drug should be discontinued and the patient treated with the usual agents, e.g., pressor amines, antihistamines and corticosteroids.

PRECAUTIONS: Penicillin should be used with caution in individuals with histories of significant allergies and/or asthma.

The oral route of administration should not be relied on in patients with severe illness, or with nausea, vomiting, gastric dilatation, cardiospasm, or intestinal hypermotility.

Occasional patients will not absorb therapeutic amounts of orally administered penicillin.

In streptococcal infections, therapy must be sufficient to eliminate the organism (10 days minimum); otherwise the sequelae of streptococcal disease may occur. Cultures should be taken following completion of treatment to determine whether streptococci have been eradicated.

Prolonged use of antibiotics may promote the overgrowth of nonsusceptible organisms, including fungi. Should superinfection occur, appropriate measures should be taken.

ADVERSE REACTIONS: While the incidence of reactions to oral penicillins is much less than with parenteral therapy, it should be remembered that all degrees of hypersensitivity, including fatal anaphylaxis, have been reported with oral penicillin.

The most common reactions to oral penicillin are nausea, vomiting, epigastric distress, diarrhea, and black hairy tongue. The hypersensitivity reactions reported are skin eruptions (maculopapular to exfoliative dermatitis), urticaria and other serum sickness reactions, laryngeal edema, and anaphylaxis. Fever and eosinophilia may frequently be the only reaction observed. Hemolytic anemia, leucopenia, thrombocytopenia, neuropathy, and nephropathy are infrequent reactions and are usually associated with high doses of parenteral penicillin.

HOW SUPPLIED: Pfizerpen VK (potassium phenoxymethyl penicillin) for Oral Solution. Each 5 ml. of reconstituted solution contains potassium phenoxymethyl penicillin equivalent to 125 mg. (200,000 units) or 250 mg. (400,000 units) of phenoxymethyl penicillin.

125 mg. bottles of 100 ml. and 150 ml.
250 mg. bottles of 100 ml. and 150 ml.

Pfizerpen VK (potassium phenoxymethyl penicillin) Tablets. Each tablet contains potassium phenoxymethyl penicillin equivalent to 250 mg. (400,000 units) or 500 mg. (800,000 units) of phenoxymethyl penicillin.

250 mg. bottles of 100.
500 mg. bottles of 100.

More detailed professional information available on request.

PFIZER INC., NEW YORK, N.Y. 10017

PFIZERPEN® COMES THROUGH AGAIN.

Now there are *two* ways to cut the cost of brand-name penicillin therapy.

Pfizerpen VK now joins Pfizerpen G (potassium penicillin G) for *true* economy in brand-name penicillin therapy.

When you write penicillin VK, it's for acid stability, solubility and rapid absorption. But when you write **Pfizerpen VK**, you add economy. Pfizerpen VK, more economical than the two leading brand-name penicillin VK products. G or VK. Just make sure it's Pfizerpen.

Tablets and Powder for Syrup

coughs are back...

"For generations my family has insisted on Donnagel®-PG," says active young matron Mrs. T. Farnsworth Lipp (of the Upper Lipps), shown here with her charming son. "All the benefits of paregoric—without the unpleasant taste, don't you know? And Junior thinks Donnagel-PG tastes so much like bananas that I never worry about a slip between spoon and Lipp."

A Matter of Taste

With or without a silver spoon, a most tasteful solution in treating acute, non-specific diarrheas: all the benefits of paregoric, without the unpleasant taste. Donnagel®-PG treats accompanying cramping, tenesmus, and nausea as well as the diarrhea itself. Instead of unpleasant-tasting paregoric, it contains the therapeutic equivalent, powdered opium, to promote the production of formed stools and lessen the urge. And it provides the demulcent-detoxicant effects of kaolin and pectin, plus the antispasmodic benefits of belladonna alkaloids. And a good banana flavor to baby any taste.

Donnagel®-PG

Donnagel with paregoric equivalent

℞ Available on oral prescription or without prescription under limited circumstances as modified by applicable state law.

Each 30 cc. contains: Kaolin, 6.0 g.; Pectin, 142.8 mg.; Hyoscyamine sulfate, 0.1037 mg.; Atropine sulfate, 0.0194 mg.; Hyoscine hydrobromide, 0.0065 mg.; Powdered opium, USP, 24.0 mg. (equivalent to paregoric 6 ml.) (Warning: may be habit forming); Sodium benzoate (preservative), 60.0 mg.; Alcohol, 5%. A.H. Robins Company, Richmond, Virginia 23220

clear the tract!

The coughing season is here again. Time to rely on the four Robitussins and Cough Calmers to help clear the lower respiratory tract. All contain glyceryl guaiacolate, the efficient expectorant that works systemically to help increase the output of lower respiratory tract fluid. The enhanced flow of less viscid secretions soothes the tracheobronchial mucosa, promotes ciliary action, and makes thick, inspissated mucus less viscid and easier to raise. Available on your prescription or recommendation.

For coughs of colds and "flu"

Robitussin®

Each 5 cc. contains:

Glyceryl guaiacolate	100.0 mg.
Alcohol, 3.5%	

For unproductive allergic coughs

Robitussin A-C®

Each 5 cc. contains:

Glyceryl guaiacolate	100.0 mg.
Pheniramine maleate	7.5 mg.
Codeine phosphate	10.0 mg.
(warning: may be habit forming)	
Alcohol, 3.5%	

Non-narcotic for 6-8 hr. cough control

Robitussin-DM®

Each 5 cc. contains:

Glyceryl guaiacolate	100.0 mg.
Dextromethorphan hydrobromide	15.0 mg.
Alcohol, 1.4%	

Clears sinuses and nasal stuffiness as it relieves cough

Robitussin-PE®

Each 5 cc. contains:

Glyceryl guaiacolate	100.0 mg.
Phenylephrine hydrochloride	10.0 mg.
Alcohol, 1.4%	

Robitussin-DM in solid form for "coughs on the go"

Cough Calmers®

Each Cough Calmer contains:

Glyceryl guaiacolate	50.0 mg.
Dextromethorphan hydrobromide	7.5 mg.

In Memoriam

We begin to die as soon as we are born, and the end is linked to the beginning.—Manilius

JOEL L. E. PETERSON, M.D.

Dr. Joel L. E. Peterson, 75, St. Paul physician, died October 5. A native of Wilton, North Dakota, Dr. Peterson had lived in the St. Paul area for the past 43 years. A graduate of Gustavus Adolphus College and the University of Minnesota Medical School, he had been in private practice for 41 years.

Dr. Peterson was a member of the Ramsey County Medical Society and the American Medical Association and a Life Member of the Minnesota State Medical Association.

He is survived by a daughter, Mrs. Roy Gustafson, and two sons, Orville J. and Fred J.

HENRY B. TROOST, M.D.

Dr. Henry B. Troost, 66, Mankato internist, died July 12. Born in Mankato, Dr. Troost attended the University of Minnesota Medical School.

He was on the staff of St. Joseph's and Immanuel Hospitals in Mankato and a member of the Blue Earth County Medical Society and the American Medical Association. Dr. Troost was also an Associate Member of the Minnesota State Medical Association.

He is survived by his wife, Betty.

ELMER W. LIPPMANN, M.D.

Dr. Elmer W. Lippmann, 67, Hutchinson physician, died July 23. Born in Gibbon, Minnesota, Dr. Lippmann had attended the University of Minnesota Medical School.

He was a member and a past president of the McLeod County Medical Society, a member of the American Medical Association and the Minnesota State Medical Association.

Dr. Lippman is survived by his wife, Rose, and a son.

WILLIAM A. BRAND, M.D.

Dr. William A. Brand, 95, Redwood physician for 70 years, died September 26. A University of Minnesota Medical School graduate, Dr. Brand continued working until a month before his death.

He was a member of the Kandiyohi-Swift-Meeker County Medical Society and the American Medical Assoication and a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Brand is survived by his wife, Bernese, and three grandchildren.

SAMUEL T. SANDELL, M.D.

Dr. Samuel T. Sandell, 63, Nopeming, died last February 11. A native of Eveleth, he was a 1937 graduate of the University of Minnesota Medical School. He served on the staff of Glen Lake Sanatorium, Minneapolis, from 1939 to 1944; on the staff of Nopeming Sanatorium from 1944 to 1954, and as the medical director of Middle River Sanatorium, Hawthorne.

He was a member of the American Medical Association, St. Louis County Medical Society, the American Thoracic Society, American College of Chest Physicians and the Minnesota State Medical Association.

Dr. Sandell is survived by his wife, Christine, a daughter, and a son, Dr. Emmett G. Proctor.

CLIFFORD O. ERICKSON, M.D.

Dr. Clifford O. Erickson, 63, one of the founding partners of the Minneapolis Clinic of Phychiatry and Neurology, died October 25. He had been a psychiatrist with the state hospital system from 1937 to 1946, serving in Fergus Falls and Rochester, and then was in private practice in Minneapolis until he helped found the clinic. He was a past chief of psychiatry of the clinic.

Dr. Erickson was a past president of the Minnesota Psychiatrict Society, a clinical associate professor of psychiatry at the University of Minnesota, and a member of the American Medical Association, the Hennepin County Medical Society and the Minnesota State Medical Association.

He is survived by his wife, Bernice, a son, Bruce, and a daughter, Lois.

NORBERT J. KULZER, M.D.

Dr. Norbert Kulzer, 65, Hastings physician, died October 21, in the snow-covered Missionary Ridge area of Durango, Colorado. He was on a hunting trip.

He was a member of the American Medical Association, the Washington County Medical Society and the Minnesota State Medical Association.

Dr. Kulzer is survived by his wife, Margaret, and two sons.

MANLEY F. FELLOWS, M.D.

Dr. M. Fording Fellows, 69, Duluth ophthalmologist, died November 24. He had practiced medicine in Duluth for about 40 years. Born in Belvidere, Illinois, Dr. Fellows graduated from the University of Illinois Medical School and did graduate work in ophthalmology at the University of Minnesota.

He was a member of the St. Louis County Medical Society, the Minnesota State Medical Association, American Medical Association, a fellow of the American Academy of Ophthalmology and Otolaryngology and a member of the Minnesota Academy of Ophthalmology and Otolaryngology.

Dr. Fellows is survived by his wife, Pauline, a son and a daughter.

Legislative

Medicredit

And Other National Health Insurance Proposals

SUBTLY BUT NOTICEABLY, many Americans from various strata of society and economic classes are adopting the idea that good health care like good education ought to be a fundamental right of citizenship.

In a policy statement adopted by the House of Delegates in December, 1966, the American Medical Association stated, "It is a basic right of every citizen to have available to him adequate health care; it is a basic right of every citizen to have a free choice of physician and institution . . . the medical profession using all means at its disposal, should endeavor to make good medical care available to each person. . . . Health care for the poor should not be disassociated from, but rather should be a vital part of the overall health care system."

In an attempt to meet these stated objectives the American Medical Association had introduced into the 92nd Congress HR 4960, the Fulton-Broyhill Bill, known as the Health Care Insurance Act and commonly called MEDICREDIT. The companion bill has been introduced in the U.S. Senate as S. 987 by Senator Clifford Hansen of Wyoming.

The American Medical Association's Medicredit bill is a federally-financed program providing protection against ordinary and catastrophic expenses of illness and accident for all individuals and families, regardless of income levels. It is a system of voluntary comprehensive health insurance covering all persons under 65. Medicare would continue for persons 65 or older.

Under the basic portion of Medicredit, the government would pay 100% of the insurance premium for individuals and families whose incomes for a taxable year would not produce any income tax. For others, the government would give partial support based on a scale from 99% to 10%. Individuals or families with a low income tax would receive more financial assistance than those with a higher income tax. As the amount of income tax rises, federal assistance would decrease. Medicredit is, therefore, designed to give maximum help to those who need it most, and minimum help to those who are best able to pay their own way.

Under the catastrophic portion of Medicredit, the government would pay the entire premium for catastrophic health insurance without regard to income level.

A person or family eligible for full payment of the basic coverage premium by the government would receive a certificate to obtain qualified health care insurance. Those who receive partial assistance could choose between a credit against income tax or a certificate for the amount of the assistance. The insurance carrier who receives these certificates would present them to the government for redemption.

In order to be included in the Medicredit program, an insurance plan would have to meet all state regulations, provide certain minimum coverage, make coverage available without restriction on pre-existing health conditions and guarantee annual renewal. An assigned risk insurance pool among the insurance carriers would be utilized when appropriate.

Medical care under a qualified basic plan would include all medical services (diagnostic, therapeutic, and preventative) provided by or under the direction of a doctor of medicine or a doctor of osteopathy. Basic benefits would provide 60 days of inpatient hospital care in a 12-month policy period. Within the 60-day limit, two days in an extended care unit would count as only one day.

Such services would consist of the diagnosis or treatment of illness, psychiatric care, well baby care, inoculation and immunization, examination, consultation, and services for pregnancy and any of its complications. Cosmetic surgery would be provided when necessary to correct deformities sustained through injury or illness. Additional benefits would include emergency or outpatient hospital services, ambulance services, and dental or oral surgery when related to fractures of the jaw.

The basic coverage of any policy purchased under Medicredit would contain a set of deductibles or an amount the patient pays before the program itself begins to meet expenses. These deductibles are computed as follows: $50.00 for hospital stay; 20% of the first $500.00 of medical expenses; and 20% of the first $500.00 of emergency or outpatient expenses.

The catastrophic protection would pay expenses for services in a hospital in excess of the 60-day basic coverage limit as well as an additional 30-day treatment in an extended care facility. Unlimited physician services would continue to be provided under the basic coverage. If the basic benefits should become exhausted, a set of deductibles would come into play under the catastrophic coverage. The amount of the deductible would be based on the individual's or family's taxable income remaining after allowable deductions and personal exemptions; 10% on the first $4,000; 15% on the next $3,000, and 20% thereafter. This deductible would be eliminated in some cases and reduced in every case by the deductibles paid under basic coverage. The cost of Medicredit has been estimated to be $14.5 billion for the first year.

At least 40 other bills containing combinations of the words "national", "health", and "insurance" will compete with the AMA's Medicredit proposal for congressional consideration this session.

The bills that have received the most support, in brief, are these:

The National Health Insurance Partnership Act

Introduced by the Nixon administration, this plan would require employers to provide health insurance with a uniform level of benefits to all employees, while a companion family health insurance plan would use general tax revenues to underwrite policies for low income families with children replacing that part of the Medicaid program. Under this program, employees could elect to be enrolled in health maintenance organizations, the development of which will be encouraged, rather than receive the basic coverage through private insurance carriers. Estimated cost of this program would be $12.4 billion per year.

The Health Security Act

Sponsored by Senator Kennedy with the backing of organized labor, this proposal would pay almost all the health expenses of all Americans through a combination of general tax revenues and payroll levies. Allotments would be made to local regions for payments to physicians by salary, special stipend, capitation fee for service or other methods. Fee schedules would be established and all physician payments would be made directly by the government. The Social Security Administration estimates that the Kennedy plan would cost about $77 billion annually, amounting to a yearly tax impact of $1,271 on a typical family; present health programs cost the average household $405 yearly.

National Health Care Act

Backed by the Health Insurance Association of America, this bill would provide both tax credits and policies for the poor, but would have the states play a major role in the program's administration. This bill also has provisions relating to the supply of health manpower, the promotion of ambulatory care, health planning, and cost and quality. The HIAA plan is estimated to cost $15 billion annually.

National Health Insurance and Health Service Improvement Act

Introduced by Senator Javits, the plan would provide a system of national health insurance to be implemented by expanding the present Medicare program to include all individuals. SSA estimates the Javits bill would cost $66.4 billion in 1975 when fully implemented.

The Catastrophic Illness Insurance Act

Sponsored by Senator Long, the bill would amend the Social Security Act to provide coverage for the catastrophic cost of protracted or severe illness. The program would be financed by a gradual increase in the Social Security tax rate.

The Extra Care Plan

Introduced by Representative Durwood Hall, a physician, the Extra Care Plan would establish a program of basic health care protection for the medically indigent and catastrophic illness insurance for everyone. Complete cost estimates on the Long and Hall bills are not available.

Congressman Wilbur Mills, chairman of the House Ways and Means Committee, has indicated he will also introduce a compromise type bill for consideration by his committee.

Congressional hearings on these and other proposals will continue to play to packed houses as national health insurance will figure prominently in the 1972 election year issues. Medicredit has, however, engendered more congressional support than any of the proposals introduced to date.

One hundred and sixty congressmen are currently listed as sponsors of the AMA's Medicredit bill including Minnesota's Congressmen Ancher Nelsen and John Zwach, Senator Clifford Hansen, in testimony before the House Ways and Means Committee, noted that Medicredit "is a bill which will work, a bill which makes sense and an approach which the American people will support and can afford."

Medicredit does not require restructuring the entire health care system, which provides care very well for the vast majority of Americans. Some of the other programs before Congress would dismantle what now exists and rebuild it along untried lines. It does not hold up group practice or any other form of medical practice as the best or only effective system of patient care. Medicredit permits flexibility and innovation in developing new more efficient ways to take care of people. It permits free choice of physician by every patient and free choice by every physician as to how he will conduct his practice.

Finally, Medicredit does not obligate the government—the nation's taxpayers—to pay for care of people who can afford to handle most of their medical problems themselves.

Classified Advertisements

Classified advertising rates are thirty (30) cents a word; minimum monthly charge $7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

WANTED NOW: General Practitioner and a Surgeon to join our three-doctor Clinic in Northwest Wisconsin Resort, Forest and Retirement Area Town of 2,400 with a patient population of 25,000. Fully equipped modern Clinic building, with new accredited 50-bed Hospital and 50-bed extended care nursing home. Deer, ducks, partridge and fish 5 minutes away. Generous salary commensurate with training and experience the first year, then full partnership. Brochure with maps and photos upon request. Call collect or write L. J. Olson, M. D., Spooner Clinic Ltd., Spooner, Wisconsin 54801, telephone 715-635-2151.

AVAILABLE—Young married G.P. with some surgical experience. Deferment not needed. Write Minnesota Medicine, 462, 375 Jackson St., St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER wanted to take over busy and well established practice. Good nearby hospitals. Little or no capital investment. Excellent office facilities. Write or call A. M. Jensen M.D., Telephones: Office (612) 328-5223, Res. 328-4428. Brownton, Minnesota 55312.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

GENERAL PRACTITIONER to join young 5 man family practice group. College town of 7,000 serving approximately 20,000 population. Accredited hospital with specialist consulting staff. 30 miles from St. Paul-Minneapolis, Minnesota. Contact J. C. Palmquist, M.D., River Falls Medical Clinic, River Falls, Wisconsin 54022. Phone (715)-425-5322.

MOTHER'S AID—Mature, experienced, educated (B.S. Education) girl to help with children in Minneapolis area. Board, room, negotiable stipend. (701) 838-0023.

WHITE BEAR SUBURBAN area needs medical doctors. Will build and lease choice location intersection Hiway 61 and 244—heart of "Auto Shopping Center." Dick Hansen—426-4834 or 484-6582.

ARE YOU TIRED OF THE SMOG, traffic congestion, sociological problems, crime and other irritations which have become part of today's urban living? Well then DISCOVER WATERTOWN, WISCONSIN. Exchange all the big city unpleasantries for the peaceful environment and easy going pace of a residential city. Watertown, a progressive community, is ideally located equi-distant between Milwaukee and Madison in southeastern Wisconsin's lake district. The community has a trade (and medical practice) area serving 40 - 50,-000 people. Many new schools, parks, trees and recreational opportunities. A stable economy. Our new Community Health Care Center with its beautiful 110 bed general hospital, connecting (but separate) 24 unit Medical-Dental Office Building (choice of suites still available), and connecting 130 bed Nursing Home, was completed in the Spring of 1971. WE URGENTLY NEED another Internist, an Otolargyngologist, an Ophthalmologist, Obstetrician-Gynecologists, and Family Practitioners to join existing medical staff. An immediate successful practice assured. Excellent rapport with the University of Wisconsin Medical School at Madison, and the Medical College of Wisconsin (formerly Marquette University School of Medicine) at Milwaukee. Medical Staff leading and supporting recruitment effort. Write or call Dr. Paul Glunz, Watertown Memorial Hospital, Watertown, Wis., 53094. Telephone 414-261-4210.

LOCUM TENENS WANTED for July and August, 1972 in Northwest Wisconsin Resort Area Incorporated Practice. Pay $2,000 per month. Will welcome applicant for any other month. Permanent association could result. Send profile to Box 463 Classified Advertisements, c/o Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

PSYCHIATRIC RESIDENCIES—Excellent, approved psychiatric training; both demanding and clinically rich with a stimulating, well-balanced program. Affiliated with Michigan State University's College of Human Medicine. The setting is a culturally satifying community; the serene, scenic Grand Traverse Bay area. Three year plan: $12,215 to $13,885; five-year plan; $13,927 to $26,121. Contract Dr. Paul E. Kauffman, Director of Psychiatric Training Room 166, Traverse City State Hospital, Traverse City, Michigan 49684. Phone (616) 947-5550. An equal opportunity employer.

WANTED NOW: General Surgeon to practice with 10 man group in Hibbing, Minnesota. Great area for one interested in hunting, fishing, snowmobiling, skiing, or any out or door living. Superior schools, junior college. Modern clinic building but two blocks from excellent hospital facilities. Patient area of 50,000. Compatible staff. Call collect or write to: John J. Muller, M.D. or O. A. Seavey, Administrator, Adams Clinic, P. A., Hibbing, Minnesota 55746. Telephone: 218-262-3425.

LOCUM TENENS WANTED—INTERNIST: Board certified, University trained; available August, Sept., October. Will consider general practice or E.R. Twin City, St. Cloud areas. (612) 566-7908.

T_4 IS THE PREDICTABLE HORMONE BECAUSE IT LOVES PROTEIN.

SYNTHROID® (sodium levothyroxine) is pure synthetic T_4, the major circulating thyroid hormone. It is reliable to use because of its affinity for protein-binding sites in the blood. T_3 is more fickle. Sometimes it binds. Sometimes it doesn't. T_4 more *predictably* binds to protein.

ALL THYROID-FUNCTION TESTS ARE USEFUL IN MONITORING SYNTHROID THERAPY

No calculations are needed, test interpretation is simple.

Any of the commonly used T_4 thyroid function tests (P.B.I., T_4 By Column, Murphy-Pattee, Free Thyroxine) are useful in monitoring patients on T_4 because they *all* measure T_4. Patients on SYNTHROID are thereby easy to monitor because their results will fall within predictable, elevated test ranges. Of course, clinical assessment is the best criterion of the thyroid status of the drug-treated patient.

TEST	HYPOTHYROID	SYNTHROID THERAPEUTIC NORMAL
P.B.I.	Less than 4 mcg %	6-10 mcg %
T_4 By Column	Less than 3 mcg %	7-9 mcg %
T_3 (Resin)	Less than 25%	27-35%
T_3 (Red Cell)	Less than 11%	11.5-18%
Free Thyroxine	Less than 0.7 nanograms %	0.7-2.5 nanograms %
Murphy-Pattee	Less than 2.9 mcg %	4-11 mcg %

TWO GOOD REASONS WHY THE ROAD TO NORMALIZED THYROID STATUS IS SO SMOOTH FOR THE SYNTHROID PATIENT

(1) The onset of action of T_4 is gradual. It has a long in vivo "half-life" of over six days. (Occasional missed doses or accidental double-doses are of little concern because of this factor) (2) since SYNTHROID contains only T_4, the potential for metabolic surges traceable to more potent iodides (T_3) is eliminated.

AS WITH ANY THYROID PREPARATION, CAUTIOUS OBSERVATION OF THE PATIENT DURING THE BEGINNING OF THERAPY WILL ALERT THE PHYSICIAN TO ANY UNTOWARD EFFECTS.

Side effects, when they do occur, are related to excessive dosage. Caution should be exercised in administering the drug to patients with cardiovascular disease. Read the accompanying prescribing information for additional data or write Flint Laboratories.

Choose the Smooth Road ...to thyroid replacement therapy

?ATIENTS CAN BE SUCCESSFULLY MAINTAINED ON A)RUG CONTAINING THYROXINE ALONE.

'hyroxine (T_4) is, as you know, ne major circulating hormone roduced by the thyroid gland. $_3$ is also produced, in smaller mounts, and is active at the ellular level. For years it has been working hypothesis among ndocrinologists that T_4 is onverted by the body to T_3. In 970 this process, called deiodination," was demonstrated y Braverman, Ingbar, and Sterling[2]. $_4$ does convert to T_3, though the recise quantities are still being tudied.

The conversion has been linically demonstrated during the dministration of T_4 to athyrotic atients. Their thyroid status is ormalized on SYNTHROID alone, et the presence of T_3 in these atients has been clearly shown.

WHY DOES SYNTHROID COST LESS THAN SYNTHETIC DRUGS CONTAINING T_3?

Very simple. T_3 costs more to make synthetically than does T_4. So it is economically necessary for a synthetic thyroid medication containing T_3 to cost more than one containing T_4 alone. Synthetic combinations cost patients nearly 50% more than SYNTHROID[3] because the T_3 costs more to start with; also there is the additional expense of formulating a tablet containing two active ingredients.

Synthroid®
(sodium levothyroxine)

THE FACTS ARE CLEAR AND HERE S OUR OFFER.

ACTS:
ynthetic thyroid drugs are an nprovement over animal gland roducts. Patients, even athyrotic nes, can be completely aintained on SYNTHROID (T_4) lone. Thyroid function tests are asy to interpret since they are *redictably* elevated when the atient adheres to SYNTHROID. f all synthetic thyroid drugs, YNTHROID is the most conomical to the patient.

A

OFFER:
Free TAB-MINDER medication dispensers to start or convert all your hypothyroid patients to SYNTHROID. Free information to physicians on role of thyroid function tests in a new booklet titled: "Guideposts to Thyroid Therapy." Ask us.

Name _____

Address _____

City _____ State _____ Zip _____

Indications: SYNTHROID (sodium levothyroxine) is specific replacement therapy for diminished or absent thyroid function resulting from primary or secondary atrophy of the gland, congenital defect, surgery, excessive radiation, or antithyroid drugs. Indications for SYNTHROID (sodium levothyroxine) Tablets include myxedema, hypothyroidism without myxedema, hypothyroidism in pregnancy, pediatric and geriatric hypothyroidism, hypopituitary hypothyroidism, simple (nontoxic) goiter, and reproductive disorders associated with hypothyroidism. SYNTHROID (sodium levothyroxine) **for Injection** is indicated for intravenous use in myxedematous coma and other thyroid dysfunctions where rapid replacement of the hormone is required. The injection is also indicated for intramuscular use in cases where the oral route is suspect or contraindicated due to existing conditions or to absorption defects, and when a rapid onset of effect is not desired.

Precautions: As with other thyroid preparations, an overdosage may cause diarrhea or cramps, nervousness, tremors, tachycardia, vomiting and continued weight loss. These effects may begin after four or five days or may not become apparent for one to three weeks. Patients receiving the drug should be observed closely for signs of thyrotoxicosis. If indications of overdosage appear, discontinue medication for 2-6 days, then resume at a lower dosage level. In patients with diabetes mellitus, careful observations should be made for changes in insulin or other antidiabetic drug dosage requirements. If hypothyroidism is accompanied by adrenal insufficiency, as Addison's Disease (chronic subcortical insufficiency), Simmonds's Disease (panhypopituitarism) or Cushing's syndrome (hyperadrenalism), these dysfunctions must be corrected prior to and during SYNTHROID (sodium levothyroxine) administration. The drug should be administered with caution to patients with cardiovascular disease; development of chest pains or other aggravations of cardiovascular disease requires a reduction in dosage.

Contraindications: Thyrotoxicosis, acute myocardial infarction. **Side effects:** The effects of SYNTHROID (sodium levothyroxine) therapy are slow in being manifested. Side effects, when they do occur, are secondary to increased rates of body metabolism; sweating, heart palpitations with or without pain, leg cramps, and weight loss. Diarrhea, vomiting, and nervousness have also been observed. Myxedematous patients with heart disease have died from abrupt increases in dosage of thyroid drugs. Careful observation of the patient during the beginning of any thyroid therapy will alert the physician to any untoward effects.

In most cases with side effects, a reduction of dosage followed by a more gradual adjustment upward will result in a more accurate indication of the patient's dosage requirements without the appearance of side effects.

Dosage and Administration: The activity of a 0.1 mg. SYNTHROID (sodium levothyroxine) TABLET is equivalent to approximately one grain thyroid, U.S.P. Administer SYNTHROID tablets as a single daily dose, preferably after breakfast. In hypothyroidism without myxedema, the usual initial adult dose is 0.1 mg. daily, and may be increased by 0.1 mg. every 30 days until proper metabolic balance is attained. Clinical evaluation should be made monthly and PBI measurements about every 90 days. Final maintenance dosage will usually range from 0.2-0.4 mg. daily. In adult myxedema, starting dose should be 0.025 mg. daily. The dose may be increased to 0.05 mg. after two weeks and to 0.1 mg. at the end of a second two weeks. The daily dose may be further increased at two-month intervals by 0.1 mg. until the optimum maintenance dose is reached (0.1-1.0 mg. daily).

Supplied: Tablets: 0.025 mg., 0.05 mg., 0.1 mg., 0.15 mg., 0.2 mg., 0.3 mg., 0.5 mg., scored and color-coded, in bottles of 100, 500, and 1000. Injection: 500 mcg. lyophilized active ingredient and 10 mg. of Mannitol, N.F., in 10 ml. single-dose vial, with 5 ml. vial of Sodium Chloride Injection, U.S.P., as a diluent. SYNTHROID (sodium levothyroxine) **for Injection** may be administered intravenously utilizing 200-400 mcg. of a solution containing 100 mcg. per ml. If significant improvement is not shown the following day, a repeat injection of 100-200 mcg. may be given.

New Orleans Graduate Medical Assembly

When The New Orleans Graduate Medical Assembly convenes again this year, it will be for their 35th annual meeting, to be held March 6-9, 1972 at The Fairmont Roosevelt Hotel. Twenty distinguished speakers, well-known for their various specialties, have been selected to report on medical advancements in their areas. Medical motion pictures, round-table luncheons, a clinicopathologic conference and entertainment for wives will add interest to the program, and a special pre-meeting Symposium by Lederle Laboratories is planned for Sunday March 5th entitled "Our Polluted Environment—Its Problems for the Clinician."

This program is acceptable for twenty-two (22) prescribed hours and eight (8) elective hours by the American Academy of Family Physicians. For further information write to The New Orleans Graduate Medical Assembly, 1430 Tulane Ave., New Orleans, La. 70112.

COLLEGE OF PHYSICIANS
MAR 15 1972

an Pilgrimage"

Robert L. Wilder, M.D.

MARCH, 1972

The negative power of undue anxiet
in congestive heart failure...
This man thinks he can no longe
take breathing for granted.

Typical of many patients with congestive heart failure, he also suffers from severe anxiety, a psychic factor that may influence the character and degree of his symptoms, such as dyspnea. His apprehension may also deprive him of the emotional calm so important in maintenance therapy.

Aid in rehabilitation

Specific medical and environmental measures are often enhanced by the antianxiety action of adjunctive Libritabs (chlordiazepoxide). Libritabs can also facilitate treatment of the tense convalescent patient until antianxiety therapy is no longer required. Whereas in geriatrics the *usual daily dosage* is 5 mg two to four times daily, the *initial dosage* in elderly and debilitated patients should be limited to 10 mg or less per day, adjusting as needed and tolerated.

Concomitant use with primary agents

Libritabs is used concomitantly with certain specific medications of other classes of drugs, such as cardiac glycosides, diuretics, antihypertensives, vasodilators and oral anticoagulants, whenever excessive anxiety or emotional tension adversely affects the clinical condition or response to therapy. Although clinical studies have not established a cause and effect relationship, physicians should be aware that variable effects on blood coagulation have been reported very rarely in patients receiving oral anticoagulants and chlordiazepoxide HCl.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Indicated when anxiety, tension and apprehension are significant components of the clinical profile.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

Equipment and supplies for the medical profession since 1919

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

Indications: Upper respiratory congestion and hypersecretion associated with: the common cold; acute and chronic sinusitis; vasomotor rhinitis; allergic rhinitis (hay fever, "rose fever," etc.).

Contraindications: Hypersensitivity to any component; concurrent MAO inhibitor therapy; severe hypertension; bronchial asthma; coronary artery disease; stenosing peptic ulcer; pyloroduodenal or bladder neck obstruction. Children under 6.

Warnings: Advise vehicle or machine operators of possible drowsiness. Warn patients of possible additive effects with alcohol and other CNS depressants.

Usage in Pregnancy: In pregnancy, nursing mothers and women who might bear children, weigh potential benefits against hazards. Inhibition of lactation may occur.

Effect on PBI Determination and I^{131} Uptake. Isopropamide iodide may alter PBI test results and will suppress I^{131} uptake. Substitute thyroid tests unaffected by exogenous iodides.

Precautions: Use cautiously in persons with cardiovascular disease, glaucoma, prostatic hypertrophy, hyperthyroidism.

Adverse Reactions: Drowsiness, excessive dryness of nose, throat or mouth; nervousness; or insomnia. Also, nausea, vomiting, epigastric distress, diarrhea, rash, dizziness, weakness, chest tightness, angina pain, abdominal pain, irritability, palpitation, headache, incoordination, tremor, dysuria, difficulty in urination, thrombocytopenia, leukopenia, convulsions, hypertension, hypotension, anorexia, constipation, visual disturbances, iodine toxicity (acne, parotitis).

Supplied: Bottles of 50 capsules.

SK&F *Smith Kline & French Laboratories*

Trademark

ORNADE® SPANSULE®

brand of sustained release capsules

Each capsule contains 8 mg. of Teldrin®(brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; 2.5 mg. of isopropamide, as the iodide.

UNCOMMON RELIEF FOR COLD SYMPTOMS

OR-203

Old winner, new bottle.

DBI® phenformin HCl tablets of 25 mg.
DBI-TD® phenformin HCl capsules of 50 and 100 mg.

Indications: Stable adult diabetes mellitus; sulfonylurea failures, primary and secondary; adjunct to insulin therapy of unstable diabetes mellitus.
Contraindications: Diabetes mellitus that can be regulated by diet alone; juvenile diabetes mellitus that is uncomplicated and well regulated on insulin; acute complications of diabetes mellitus (metabolic acidosis, coma, infection, gangrene); during or immediately after surgery where insulin is indispensable; severe hepatic disease; renal disease with uremia; cardiovascular collapse (shock); after disease states associated with hypoglycemia.
Warnings: Use during pregnancy is to be avoided.
Precautions: 1. *Starvation Ketosis:* This must be differentiated from "insulin lack" ketosis and is characterized by ketonuria which, in spite of relatively normal blood and urine sugar, may result from excessive phenformin therapy, excessive insulin reduction, or insufficient carbohydrate intake. Adjust insulin dosage, lower phenformin dosage, or supply carbohydrates to alleviate this state. **Do not give insulin without first checking blood and urine sugar.**
2. *Lactic Acidosis:* This drug is not recommended in the presence of azotemia or in any clinical situation that predisposes to sustained hypotension that could lead to lactic acidosis. To differentiate lactic acidosis from ketoacidosis, periodic determinations of ketones in the blood and urine should be made in diabetics previously stabilized on phenformin, or phenformin and insulin, who have become unstable. If electrolyte imbalance is suspected, periodic determinations should also be made of electrolytes, pH, and the lactate-pyruvate ratio. The drug should be withdrawn and insulin, when required, and other corrective measures instituted immediately upon the appearance of any metabolic acidosis.
3. *Hypoglycemia:* Although hypoglycemic reactions are rare when phenformin is used alone, every precaution should be observed during the dosage adjustment period particularly when insulin or a sulfonylurea has been given in combination with phenformin.
Adverse Reactions: Principally gastrointestinal; unpleasant metallic taste, continuing to anorexia, nausea and, less frequently, vomiting and diarrhea. Reduce dosage at first sign of these symptoms. In case of vomiting, the drug should be immediately withdrawn. Although rare, urticaria has been reported, as have gastrointestinal symptoms such as anorexia, nausea and vomiting following excessive alcohol intake.

President's Letter

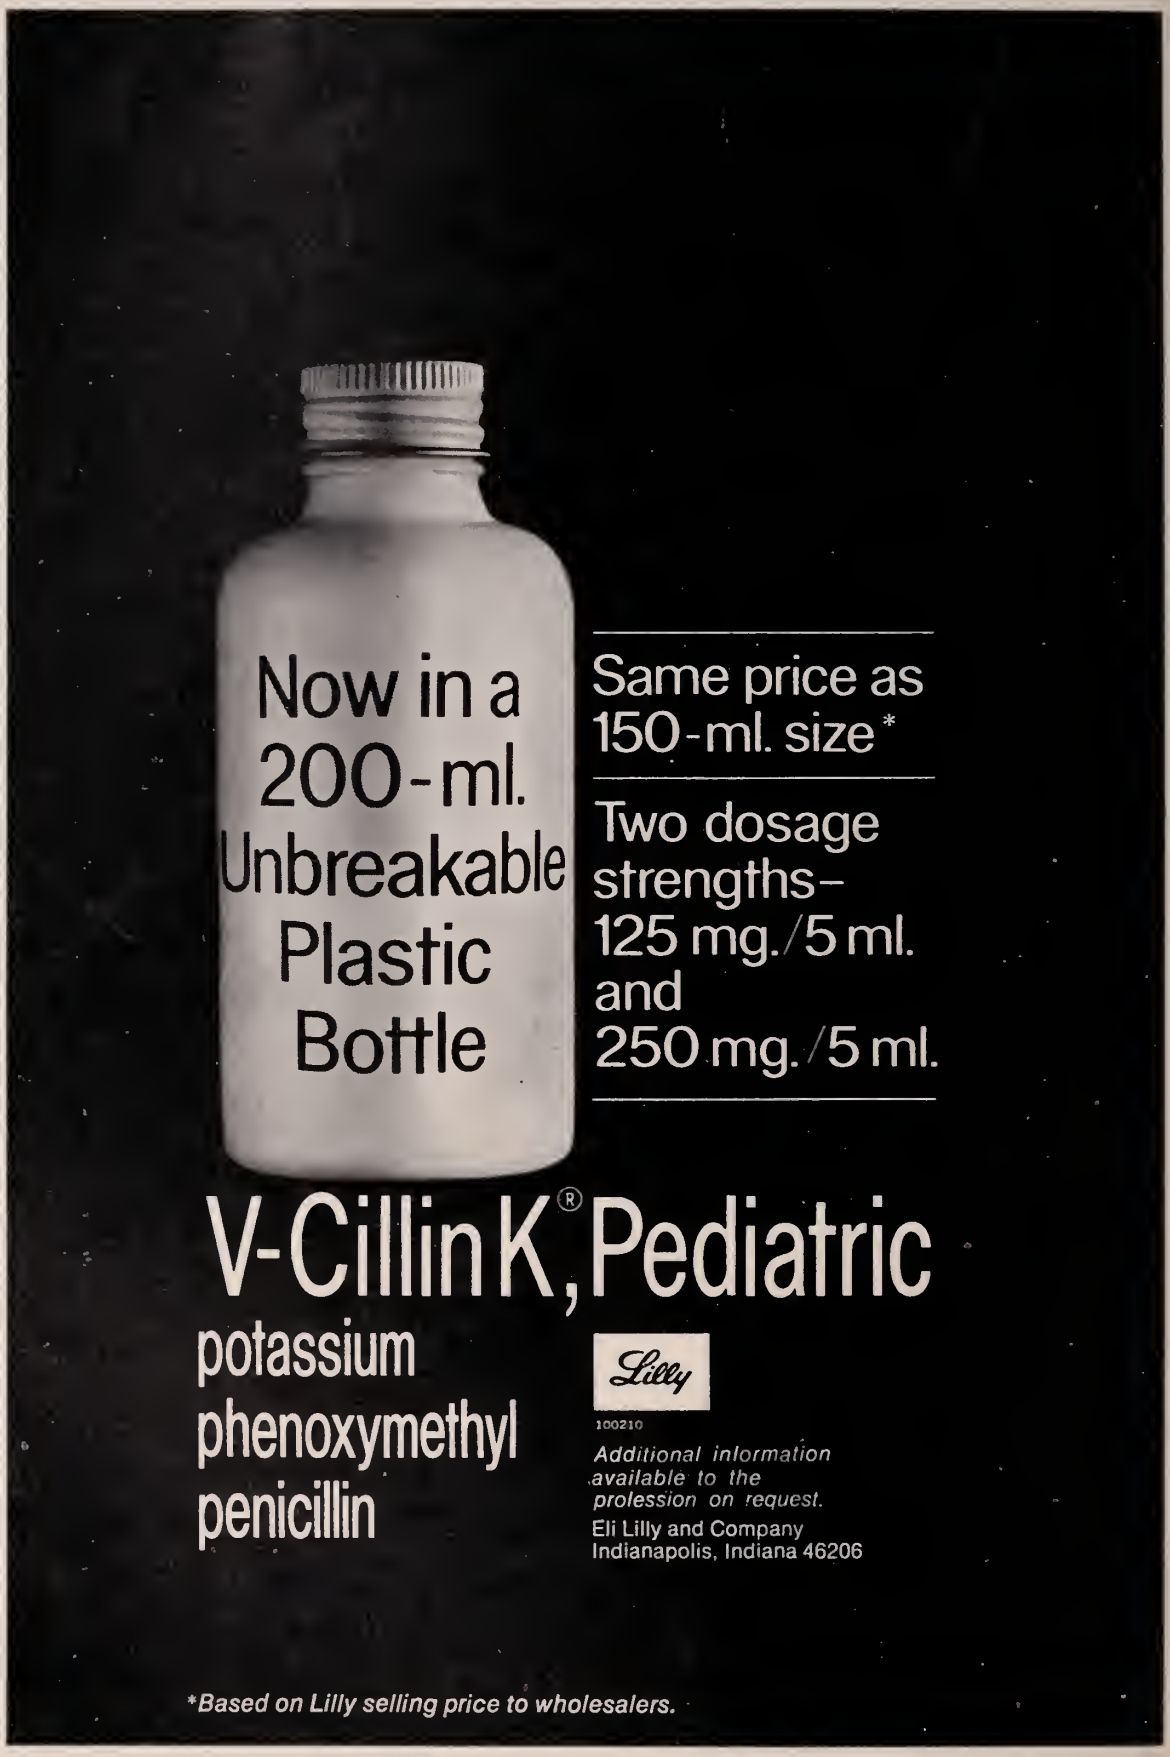
Responsibility for Rising Health Care Costs*

WHEN WE SPEAK of health care costs, we must be certain to define what we mean. Many people confuse health care costs with medical care costs. Health care involves doctor services, hospitalization, nursing home care, pharmaceuticals, ambulance service, to name a few. Last year the cost for medical care, (physician services) amounted to approximately 12-17% of the health care costs, depending on the area in the United States. Consequently, the "doctor bill" is a small fraction of the overall health care costs. We, the physicians, have a definite responsibility to help control health care costs, and this is being done through utilization review committees in which the physicians donates time to participate in the activities of these committees. These committees' functions are to see that hospitalization costs, which account for approximately 50-55% of the health care dollar, are kept to a minimum while continuing to preserve quality care for the patient.

The patient, however has just as much responsibility in controlling the cost of health care as does the physician. Last year, it was estimated that the American people spent at least $2,000,000,000 for quackery, more than all the money spent on health education. In this modern day, people still spend money on worthless and sometimes harmful gadgets ranging from a copper bracelet to the Rainbow pill for dieting. Millions are spent on unnecessary frills such as health foods, reducing aids, patent medicine and other non-prescription items which cost the American public more than all the prescription drugs put together.

Think of the enormous savings that would occur if the nation could reduce accidents. In 1969, 49,000,000 people were injured; 20,000,000 at home, 9,000,000 at work, 3,500,000 on highways and 15,000,000 in non-moving motor vehicle accidents. Of the 49,000,000 accidents, 11,000,000 were bed disabling. The cost of medical and hospital care alone for these injuries was $3,000,000,000. Nearly all of this cost was preventable. Therefore, the patient does have a real stake in controlling costs of health care.

What about the effects of alcohol? There are 60,000,000 users of alcohol in this country, which includes approximately 10,000,000 alcoholics. Medical care for these alcoholics is part of the medical care that is called too expensive. This alcohol problem, too, can be reduced.



What about the average adult who over eats, does not exercise, smokes too much and does not get enough rest. How much does this self abuse add to the cost of health care in treating hypertension, cancer of the lung, arteriosclerosis, diabetes and strokes? It might be safe to say that half the cost of health care is preventable in this country. The doctors of the nation have been urging the American public for years, to use a little common sense and follow some simple rules to maintain good health.

The responsibility for preventing rising health care costs belong to all of us. The doctors of America accept this challenge, but we must also have responsible action on the part of the American public to be successful in controlling these costs.

Cancer of the Liver

Intra-Arterial Infusion

I. E. FORTUNY, M.D.,* A. THEOLOGIDES, M.D., PH.D.* AND
B. J. KENNEDY, M.D.†

THE RESPONSE OF CARCINOMAS to specific antitumor chemotherapeutic agents is usually dose-dependent. For neoplasms limited to a specific organ, intravenous or intramuscular therapy results in a large percentage of the dose being expended on normal tissues with a relatively small amount actually reaching the tumor. The toxicity of the agent on normal tissues is a limiting factor in the total allowable amount of drug that can be administered. Injection of an agent directly into the artery supplying the tumor provides a higher concentration in the tumor, a possible greater antitumor effect, and less toxicity to normal tissues. This concept of intra-arterial administration of anti-neoplastic drugs was introduced by Klopp in 1955 for the treatment of head and neck tumors.[1]

Radiotherapy and systemic chemotherapy have proved of limited practical value for the treatment of extensive metastatic and primary cancers involving the liver. The results of surgery, in the treatment of primary biliary and pancreatic carcinomas, are discouraging, since only 20% of these tumors are resectable,[2,3] and the use of radiation or systemic chemotherapy adds little to the management of these patients.[2]

The demonstration by Bierman[4] that the blood supply to normal liver is derived mainly from the portal vein (80-95 per cent), while the blood supply to developing intrahepatic tumors is derived mainly from the hepatic artery and its branches (85 per cent), established the rationale for the trial of intra-arterial chemotherapy for neoplasms in the liver.

Selective catheterization of the desired artery may be accomplished under direct vision by introducing the catheter through a collateral branch,[5,6,7] or the catheter may be introduced percutaneously through a brachial or femoral artery and then advanced under fluoroscopy into the desired artery.[8]

Administration of the fluorinated pyrimidines, 5-fuorouracil (5-FU) and 5-fluoro-2′-deoxyuridine (FUDR), via the celiac or hepatic arteries delivers a higher drug concentration into the tumor than into normal hepatic tissue.[6,9,10] Since these drugs are metabolized in the liver their systemic toxicity is reduced when they are delivered directly through the celiac or hepatic arteries;[8,10] yet they still induce an antitumor effect.[5,7,8,10]

Method

The infusion of 5-FU via the celiac or hepatic artery after percutaneous catheterization of the femoral artery and the use of the Fenwald closed system has been used in 51 patients with cancers involving the liver.

Preliminary Procedure

Prior to catheterization the following studies were obtained: hemogram and platelet count, prothrombin time, plasma thromboplastin time, alkaline phosphatase, SGOT, LDH and bilirubin. Every three days during the infusion period the alkaline phosphatase, SGOT, and LDH were determined and a three-fold increase in any of these enzymes from the base-line values constituted an indication to discontinue the infusion. The position of the catheter was checked flouro-

†Professor of Medicine.

scopically every three days, and repositioning of the catheter was carried out when necessary.

Evaluation Procedure

Stomatitis, diarrhea, abdominal pain, or bleeding were the toxic manifestations used as indications to discontinue treatment. An objective improvement of the cancer was considered when any two of the following occurred: *1.* Fifty percent decrease in palpable liver size. *2.* Decrease in the number and size of hepatic metastases as determined by radioactive technetium sulfur colloid (Tc 99) liver scan. *3.* A return to normal of the bilirubin, SGOT, and LDH.

Subjective improvement was gauged by pain control, improvement of appetite, and weight gain, as well as by the daily performance of the patient.

Results

Biliary Tract Cases

Eleven patients with inoperable carcinomas originating in the biliary tract and involving the liver were treated by intrahepatic infusion of 5-fluorouracil. Objective improvement occurred in six of the patients and their median survival from the beginning of the study was a little more than 24 months. Two of them are alive and free of detectable disease; one is alive but jaundice has recurred (Table 2). In all of these six patients external biliary drainage was removed when jaundice disappeared.

Five of the 11 patients in this group had neither objective nor subjective improvement following the first infusion cycle of 5-FU therapy. Four had primary tumors of the gallbladder, and one, a carcinoma of the ampulla of Vater. Their median survival after admission to the study was three months.

Four patients with inoperable pancreatic carcinoma involving the liver were treated. Three had a decrease in tumor size, disappearance of pain, and weight gain. The median duration of life from the first infusion cycle was 11 months. A total of nine infusion cycles were given to this gorup.

Recurrent Colorectal Tumors

Fifteen patients had recurrent colorectal tumors involving the liver; five from the rectum, four from the sigmoid colon, three from the transverse colon, and three from the cecum. A total of 35 infusion cycles were administered to this group.

Objective tumor regressions were observed in six patients who also had an increase in appetite with a weight increase of eight to 12 pounds. (Table 3). The median duration of life from inclusion to the study was 10 months as compared to a median survival of two months for the patients who did not respond to intrahepatic infusion. *However, the total survival from primary diagnosis was the same for both groups.*

Miscellaneous Malignancies

Patients with small bowel carcinoma, hepatoma, melanoma and adenocarcinoma of unknown origin involving the liver did not respond to 5-FU infusion.

Of the four patients with liver metastasis from carcinoma of the breast, two died of drug toxicity. At post-mortem there was histologic evidence of tumor necrosis secondary to treatment. Objective tumor regression lasting six months was observed

56	M	Splenic flexure	12	12	12, alive
61	F	Cecum	4	6	50

in the other two patients.

Complications

Four deaths (7.5%) were ascribed to toxic effects of the treatment: two of them due to sepsis and intravascular coagulation, and two to severe gastrointestinal toxicity and sepsis.

Severe reversible stomatitis, diarrhea, and leukopenia were observed in two patients. Catheter thrombosis was noted in five patents (9.4%), and in 12 instances the catheter was displaced. In all instances replacement or repositioning of the catheter allowed the completion of the cycle.

Discussion

Intra-arterial infusion has provided a means to deliver a high concentration of 5-fluorouracil to metastatic tumors involving the liver in diseases where conventional intravenous administration of this agent has been relatively ineffective. Percutaneous placement of the catheter through the femoral route [7,10] or the transbrachial approach[3] has become a familiar technique for most diagnostic radiologists. The method as used in this study is inexpensive and safe, thus making this therapeutic approach easily accessible.

Intra-arterial infusion of 5-fluorouracil for the treatment of inoperable carcinoma of the biliary tract was effective in six of 11 patients with these malignancies. The median duration of objective improvement was a little more than 24 months of comfortable survival.

In the treatment of colorectal tumors involving the liver, intra-arterial infusion of 5-fluorouracil has been demonstrated by others to produce objective remissions. Wirtnen[8] reported a 60 per cent remission rate, Burrows[10] and Rochlin[5] observed objective regression in 59 and 45 per cent of their respective patients. Of our patients, six of 15 (40%) had a decrease in liver size lasting a median of 10 months.

When a diagnosis of metastatic carcinoma of the liver is established at the time of exploratory surgery the surgeon has the opportunity to select the appropriate artery in which to place a catheter, thus providing the patient with an opportunity for further selective chemotherapy. At the completion of the course of intra-arterial chemotherapy, the catheter is clamped off for 24 hours, after which it can be gently pulled out, without any subsequent bleeding.

Summary

Fifty-one patients with a variety of tumors involving the liver, treated by celiac or hepatic artery infusion of 5-fluorouracil, were sufficiently benefitted to make this therapy an effective means for the management of these diseases.

Percutaneous catheterization of the femoral artery and the use of the Fenwald closed system are simple, inexpensive, and safe. A catheter and Fenwald closed system should be available for appropriate positioning when surgical exploration for gastronintestinal malignancy is carried out. If there is liver involvement, direct visualization of the desired collateral will make the need for a second procedure, percutaneous catheterization, unnecessary.

Urinary Tract Infections

Diagnosis, Bacteriology and Treatment

JOHN M. MATSEN, M.D.*

CERTAIN BASIC PRINCIPLES regarding urinary tract infections should be kept in mind. Bladder urine is normally sterile, and the presence of bacteriuria at any point along the urinary tract up to the distal urethra constitutes a deviation from normal. The demonstration and quantitation of bacteria by culture is fundamental in establishing the diagnosis of urinary tract infections. There are two major steps in arriving at an estimate of bacterial numbers in a urinary specimen. Initially, the specimen must be properly obtained and secondly, it must be quickly transported to and appropriately handled by the laboratory. Antimicrobial therapy of urinary tract infections should be based upon a knowledge of the organism causing the infection and upon an understanding of the historical background of the infective process.

Specimen Collection

An accurate urine specimen can be obtained from a properly supervised clean catch mid-stream urine, urethral catheterization, or suprapubic bladder aspiration. However, when women are asked to obtain a clean catch urine by themselves, as few as 20% will be able to obtain sterile urines, and from 5-10% will actually have bacterial counts in excess of 100,000 organisms per ml in spite of sterile bladder urine.[1] These disturbing statistics, resulting from distal urethral contamination, are greatly improved when the clean catch mid-stream urine specimen is obtained under the close supervision and instruction from a competent nurse. The material in the Table is taken from the data of Dr. E. H. Kass and deals with the reliability of bacterial counts from clean catch urine cultures.[2] Only 50 to 75% of catheterized urine specimens in patients with known sterile bladder urine will be absolutely sterile.[3,4,5] Multiplication of bacterial numbers may occur as often as every 20-30 minutes unless the urine specimen is cultured without delay, or is properly refrigerated.

Even very low counts of bacteria may be important in patients who are being treated with antimicrobial therapy, especially if the organism cultured is in pure culture or is the organism present in the pretreatment cultures.

Office Bacteriology

For a very fine review of the office bacteriology of urine specimens, the reader is referred to the article by Stamey.[6]

Simple methods of culturing urine utilize spoon or dip-slide devices containing sterile media.[7,8] These commercially available devices are dipped into the urine and then incubated and observed for numbers of bacterial colonies and for growth characteristics. Our experience with these devices indicates that they can be used with good accuracy on freshly obtained specimens, and are especially helpful in routine screening.

For the physician who does not have ready access to a competent laboratory, transit of the urine specimen from his office to the laboratory may cause just the delay necessary to allow organism multiplication. Bacteriology done in a small laboratory within the physician's office setting can be very satisfactory and more economical for the patient. Bacteriology for urine specimens can be done rapidly and accurately using a calibrated innoculating loop and a blood agar plate and a selective differential media plate (MacConkey's or Eosin-Methylene Blue). A small incubator costs as little as $75 and takes up relatively little space. Identification of organisms, if necessary, can be readily accomplished by using the Enterotube (Roche)[9].

TABLE
Reliability of Bacterial Count from Clean Catch Urine Cultures.[2]

1st Count	Chance of 2nd count exceeding 100,000/ml (critical level)
10,000 or less	1%
100,000 or more	85%
1,000,000 or more	96%

*Departments of Laboratory Medicine and Pediatrics, University of Minnesota School of Medicine, Minneapolis.

Patho-Tec (General Diagnostics)[10] or Analytab Systems (Analytab Products, Inc.).[11] Identification of organisms is particularly useful in delineating the epidemiology of recurrent bacteriuria. Antibiotic sensitivity testing can be readily and practically accomplished by using the high potency single antibiotic disc technique.[12-15]

Antimicrobial Therapy

Uncomplicated Acute Cystitis

Infections in this category will not infrequently resolve spontaneously. Treatment is usually based on the realization that the causative organism is most often a broadly sensitive *E. coli,* especially if the infection is a first urinary tract infection. It must be stressed that while therapy may be successful in as many as 95% of patients, one cannot rely solely upon the disappearance of symptoms to judge the effectiveness of therapy, as this may not be a true indicator of bacterial eradication. In cystitis, the presence of an antimicrobial agent for a period of one hour will clear most infections limited to the lower urinary tract[16], and one or two adequate doses of an agent such as kanamycin or cephaloridine will usually result in a bacteriological cure.[17] In truth, this ability to clear cystitis with seeming ease can be a helpful diagnostic tool in differentiating upper from lower urinary tract infection. The best approach then, to patient therapy, whether it be in uncomplicated or recurrent cystitis, would be to repeat a urine culture two to four days after beginning treatment, and thereafter two or three cultures at least should be spaced over the period of six to 12 months.

Since the organism being treated in the vast majority of cases of acute cystitis is a susceptible *E. coli* one has wide latitude in choosing an antimicrobial agent. There is no convincing evidence that any one antimicrobial agent is better than another, be they bactericidal or bacteristatic as long as the result of that therapy is a sterile urine. Sulfonamides are usually adequate, inexpensive and well tolerated. Other agents which may be considered would include nitrofurantoin, ampicillin, an oral cephalosporin, naladixic acid or, in adults, tetracyclines.

Acute Pyelonephritis

Therapy in pyelonephritis will in part be dependent upon the severity of the acute infection, and will frequently depend on whether or not the patient is hospitalized. In the more severe episodes, especially if vomiting is a part of the patient's clinical picture, parenteral medication is indicated. In recurrent or chronic situations with an acute episode, one should realize that other organisms such as *Klebsiella, Proteus,* or *Pseudomonas* may be involved. Our recommendation would be that in a severe episode of pyelonephritis one institute therapy with kanamycin, gentamicin or polymyxin B after obtaining an initial impression of the presence of gram negative organisms by the gram stain. A word of caution is indicated here since one can have a negative gram stain in the presence of subsequent culturally proven bacteriuria.[18] This can be the situation in twenty percent of instances with 100,000 organisms per ml, although the gram stain correlation is much better if there are over 1,000,000 organisms per ml. Culture results will furnish an accurate organism diagnosis and allow for revision of therapy if it is indicated. One should remember that enterococci and staphylococci can cause urinary tract infection and should be considered among etiologic possibilities. Treatment of acute pyelonephritis is probably best maintained for 10-14 days. Follow-up cultures at decreasing intervals for a year or more are necessary to insure that the patient remains infection free.

Complicated Urinary Tract Infections

Females having complicated urinary tract infections are those who frequently require urologic surgical procedures for *basic anatomic abnormalities* and/or urinary calculi.

Patients with *neurogenic bladders* (bladder paralysis) are also considered to have complicated urinary tract infections, and these patients are difficult to maintain infection free because of their difficulty in emptying adequately. Consideration should be given to surgical diversion in order to prevent renal deterioration secondary to persistent urinary infections. Our data[19] has shown that, in *intestinal urinary diversion* patients, 50% of cultures had greater than 100,000 organisms per ml, and 70% had some bacteria. No patient always had a sterile urine culture. Bacteriuria in these patients is largely asymptomatic. Studies are currently underway to determine the importance of bacteriuria in this patient population.

The possible high incidence of bacteriuria in infants[20] should also be briefly mentioned in the category of complicated urinary infections, but will not be discussed here.

Asymptomatic Bacteriuria

Kunin[21,22] has demonstrated that bacteriuria ex-

ists in about 1.48% of school girls, with two-thirds having no symtoms referable to the urinary tract. His figures indicate that at least 5% of girls will acquire bacteriuria during the elementary and high school years. This incidence increases with age until it is estimated that 10% of adult women over age 60 have bacteriuria. The majority of this population will be asymptomatic, and these patients with asymptomatic bacteriuria constitute the largest group of patients with urinary infections.[23] The presence of bacteriuria should be established by a minimum of two consecutive cultures. Specific antimicrobial therapy is based upon the results of sensitivity testing since organisms may be of a more resistant nature. The treatment is most often with an oral antimicrobial agent, and the principle of using the least toxic, most economical agent to which the organism is sensitive is usually wisest. These patients are often difficult to treat in that the bacteriuria often recurs. Recurrence in females is an indication for a urologic work-up, and for longer duration specific therapy. In the male patient and in the female pediatric patient, one considers a urologic work-up upon initially documenting the diagnosis of bacteriuria.

Recurrent Bacteriuria

A relapse has been defined as being a recurrence due to the same biotype of bacteria, whereas a re-infection is a recurrence with a new strain of the same or another species. Since at least one-half of patients with acute urinary infections and asymptomatic bacteriuria will have a recurrence after a successful course of antimicrobial therapy, it is mandatory that one know the *in vitro* susceptibility of the pathogen involved as this may well be the deciding factor in the selection of an antimicrobial agent and in determining the duration of the therapy. We have found the use of the methenamine salts, methenamine mandelate[24] and methenamine hippurate[25,26] along with urinary acidification to be effective in preventing repeated infection. These patients are advised to maintain adequate hydration, to void frequently, to maintain proper hygiene, and to avoid tub baths.

Some women may experience repeated episodes of urinary tract infection following sexual intercourse. These patients should be encouraged to maintain proper hydration, to void after intercourse, and to take one dose of an antimicrobial agent. Stamey[1] advises oral penicillin-G, 250 or 500 mg as being effective. Ronald advocates sulfisoxazole 500 mg or nitrofurantoin 50 mg as being appropriate.[23]

When the patient has well documented, recurrent urinary tract infections the recurrence rate following conventional therapy approximates 80%.[27] Thus, this group poses "the most severe therapeutic challenge."

Infection or Bacteriuria in the Male

Almost all males who develop a urinary infection or bacteriuria have an underlying urologic problem and deserve a urologic evaluation. The younger male population almost always have problems which should be approached surgically. In the older male population the underlying problem is most often either prostatic hypertrophy or calculi, with a surgical approach an advisable concommitant to antimicrobial therapy. Therapy should be dictated by sensitivity tests. There is a group of male patients who have chronic prostatic seeding of bacteria into the urinary tract. Eradication can be very difficult in certain of these individuals, and it may be best to maintain specific antimicrobial therapy in reduced dosage in order to keep bladder urine sterile and the patient symptom free.[28]

Urinary Infection in the Catheterized Patient

Prevention of infection is the best approach in these patients. Strict adherence to technique in inserting the catheter is a first step.[29,30] Subsequent use of either a closed urinary drainage system[31,32], or a system employing a continuous antimicrobial irrigation system[33,34] is strongly advocated in decreasing the incidence of catheter-induced infection. Neither of these systems is effective in patients with pre-existing bacteriuria. Systemic use of antibiotics will not prevent catheter-induced infection, and, indeed, may lead to infection with *Pseudomonas* or other relatively resistant organisms. The attempt to eradicate infection without catheter removal is very difficult at best.

Summary

To demonstrate the presence of bacteriuria one must insure that proper culturing is carried out, that the refrigerated specimen is transported to the laboratory without delay, and that quantitative bacteriology is carried out. If an organism is present in the urine, there should be either sufficient patient symptoms, or an appropriate repeat culture to confirm that infection exists. Antimicrobial

therapy is then indicated. The agent used is determined by the consideration of the location and severity of the condition being treated, the in vitro sensitivity pattern of the organism isolated, the renal and liver function of the patient, and the pharmacological and economic factors of the possible effective agents. The duration of therapy depends on the nature of the infection and the existence of history of recent prior infections.

Gynecologic Operations for Sterilization

VIGLUNDUR T. THORSTEINSSON, M.D.* AND JOSEPH H. PRATT, M.D.†

THE DESIRABILITY of sterilizing certain women is a universally accepted fact. Frequently the desirability becomes a necessity for the preservation of the health and even the life of the patient. The indications for sterilization are numerous, and certainly many of them are debatable; but most of the arguments are based on religious or moral views. It is assumed that even the most conservative physician will occasionally be faced with the necessity of sterilizing a woman. This review is not intended to deal with the many indications for or the many philosophic aspects of sterilization.

History

Sterilization of the female has been of interest to the medical profession since it first was contemplated by Hippocrates as a means of eliminating hereditary perpetuation of the insane.[1] The earliest operations were on the ovaries by oophorectomy. Von Blundell is credited with the initial written suggestion of tubal sterilization, published in 1834.[1] He suggested total resection, but he wrote that simple division might successfully prevent pregnancy. Among other earlier procedures was burying the ovaries in pockets in the broad ligaments[2]; this had the possibility of restoring fertility at a later date, if desired, by replacing the ovaries in the abdominal cavity.

In 1850, Froriep proposed the creation of a chemical slough stricture in the uterine corners to prevent pregnancy and suggested silver nitrate for that purpose.[2] Koch in 1878 used a galvanocautery to create such a slough.[3]

The same principle was revived by Dickinson in 1916, and in 1929 he described his use of the hysteroscope to visualize the tubal openings.[2] In 1934 Hyams[4] described his technique of coagulating the tubal ostia and mentioned the use of a fluoroscope for direct visualization.

Rein was the first, in 1876, to propose hysterectomy for the purpose of sterilization.[2] Having relieved a patient of sterility by removing a cervical polyp, Kock suggested establishing a cervical polyp to interfere with conception.[2] Pincus performed atmocausis (distruction of the endometrium by steam).[2] This was especially advocated by Cramer in 1904, but he reported bad results and severe colic, and sometimes a hysterectomy had to be done for complications.[3]

Between 1880 and 1910 various procedures were carried out, with uniformly poor results. An extensive report by Nurnberger in 1917 described 36 methods of tubal sterilization. He concluded that salpingectomy or cornual resection was the best.[1]

In 1919 Madlener[5] described his technique of crushing the tubes. Williams,[6] in 1921, described the utilization of cesarean hysterectomy for preventing further pregnancies. In 1924 Irving[7] described his method of tubal sterilization, and in 1930 Bishop and Nelms[8] described the Pomeroy procedure. Postpartum tubal sterilization was popularized in this country by Adair and Brown[9] who performed the operation within 24 hours after delivery. The only new procedure which has received much attention in the last decade is the one described by Uchida[10] in 1961.

Surgical Methods of Sterilization

In the restricted sense of the term, the sterilization of a woman refers to surgical procedures intended to prevent the union of spermatozoon and ovum.

Hysterectomy

The techniques for interval hysterectomy or cesarean hysterectomy will not be described here,

*Mayo Graduate School of Medicine (University of Minnesota), Rochester: Resident in Obstetrics and Gynecology.
†Mayo Clinic and Mayo Foundation: Department of Obstetrics and Gynecology.

but their advantages and disadvantages will be discussed below.

Salpingectomy

There are more than 100 variations of techniques for interruption of the continuity of the tubal lumen to prevent conception. Of these, only a few are now in common use. Nonpuerperal, interval tubal sterilization may be performed at any time, but the menstrual period and the immediate premenstrual and postmenstrual days should be avoided. When tubal sterilization is to be done in the puerperium, however, it should be performed as soon as possible and not later than 48 hours after delivery. After that time, increasing edema makes the operation more difficult, with higher incidences of hemorrhage, infection, and failures. The edema subsides by the seventh to the 10th day but by that time the involution of the uterus has rendered the tubes more inaccessible, thus making the operation unneccessarily extensive and risky. If the operation cannot be accomplished during the first 48 hours after delivery, it should be delayed until six to eight weeks later.

Complete Salpingectomy

This was recommended by some of the earlier writers as one of the safest operations for accomplishing sterility, at a time when surgeons were discouraged by the high failure rate of the then known procedures. However, the simpler partial salpingectomies give results essentially the same as those of complete salpingectomy.

Partial Salpingectomy and Tubal Ligation

In 1906 Friedemann described a method of sterilization in which the tube was crushed and then ligated with catgut[5]. Madlener[5], in 1919, described an operation with the same principle; instead of an absorbable ligature, however, he used cotton thread.

Madlener Operation

The tube is grasped with a thumb forceps in the middle or more lateral portion and is pulled up at an approximately 90° angle (Figure 1). With a Doyen intestinal clamp (which has a 9-mm crushing surface) the loop of the tube is crushed in the coronal plane, involving a part of the mesosal-

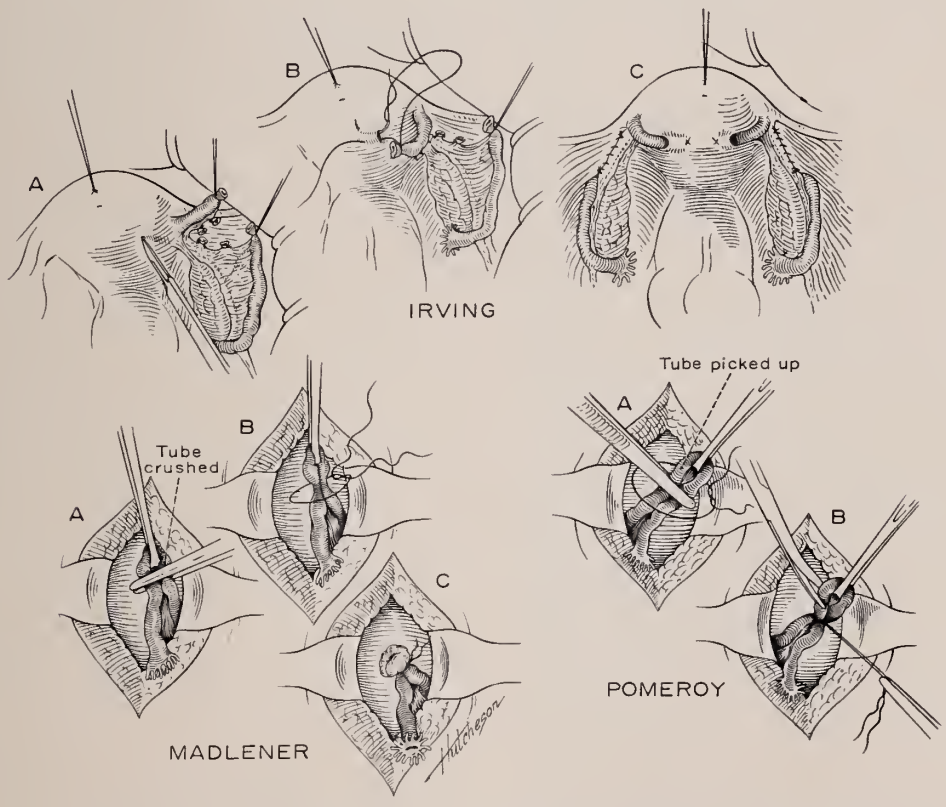

Fig. 1—Principles of Madlener, Irving, and Pomeroy procedures for tubal ligation. Note that in Pomeroy procedure loop is grasped with thumb forceps, not crushing clamp, to lead ligation. In Madlener technique, no tubal tissue is excised.

pinx. The crushing should be forceful enough so that the tissue becomes paper thin. The loop is then ligated with a thin cotton thread. The tissue should not be traumatized beyond the clean crushing.

In 1932 Madlener[11] reported a total of 166 cases over 22 years without a known failure. Von Waser reported one failure in 225 cases[12]. In 1933 Gianella, who introduced a modification by suturing the crushed tube beneath the round ligament, collected 604 cases with only one subsequent pregnancy[1]. The failure rate for this operation in the hands of many other surgeons increased over the next decades and, according to Garb[1], the overall failure rate is 1.44% in 7,829 cases.

Irving Operation

In this operation, described in 1924[7], the tube is elevated 1½ inches from its cornual insertion (Figure 1). The mesosalpinx beneath this point is pierced by a hemostat in an avascular area. The distal portion of the tube is ligated with 1-0 chromic catgut. Proximal to this a double suture ligature of the same material, mounted on a half-curved, round-pointed needle and knotted about three inches from its end, is tied around the tube which is then divided between the two ligatures. A stab wound is made in the myometrium at the uterine end of the tube. A sharp-pointed hemostat is then plunged into the uterine wall through this stab wound as far as its lock. Its tips are spread, thus making a pit. A grooved director is inserted in this pit as far as it will go, and the half-curved needle is passed along the director to the extreme depth of the pit and then brought out on the surface of the uterus. Traction on the ligature causes the tube to enter the pit for approximately ¾ inch. One strand of the double suture ligature is cut, a cross-stitch is made in the superficial portion of the uterine wall, and the free ends are tied, thus anchoring the tube deeply in the myometrium. The small wound at the point of the tube is closed with a figure-eight suture of chromic catgut to complete the operation.

From 1916 through 1949, 814 women were sterilized by this method at Boston Lying-In Hospital with no known failures[13]. A few failures have been reported, but there was no failure in the 1,056 cases collected by Garb[1]. The main disadtages of this operation are the amount of time it takes and the amount of bleeding it causes.

Pomeroy Operation

In 1930 Bishop and Nelms[8] described a method of sterilization which they said they had first seen performed by Ralph Pomeroy. Pomeroy had made no claim for originality but said that he had never seen it done before. In this procedure, a loop in the loose, middle portion of the tube is ligated with absorbable suture material and resected (Figure 1). Bishop and Nelms wrote, "We definitely do *not* crush the tube first . . . for the crushed tissue may open a way for fistula formation; we definitely do *not* use non-absorbable ligature material as that very material, we fear, might slough through and a fistula develop." They reported 100 cases without failure. Separation of the cut ends is considered an important point and can be achieved only by using an absorbable suture which dissolves quickly. In 1947 Nelms and Doyle[14] reported 404 cases with only one subsequent pregnancy.

In Lull and Mitchell's series[15], which extended over 25 years, there were 1,550 women, with four failures reported. Two were due to a wrong technique, but in the other two cases the Pomeroy technique had been followed explicitly. They emphasized that the loop should be made in the middle third of the tube because, if it is too close to an involuting uterus, the ligature might slip. The overall failure rate is reported by Garb[1] as 0.40% in 5,477 cases.

Uchida Operation

In 1961, a new technique of tubal sterilization was described[10] as used in nearly 5,000 cases without a failure. Through a small abdominal incision, the tube is delivered by a special hook (an Allis clamp serves as well). The serosal surface of the tube at about its midpoint is then dissected away from the muscular tube by means of subserosal injection of saline-epinephrine solution to produce considerable ballooning of the adjacent mesosalpinx. This produces local vascular spasm and neatly demonstrates avascular areas of the serosa. The latter is incised at such an area, and the muscular tube is delivered through the incision and divided. The proximal limb of the tube is stripped back and about 5 cm of it is cut off, to leave only a small stump. This is ligated with chromic catgut and allowed to fall back within the serosal balloon. A pursestring ligature of fine chromic catgut then gathers up the edges of the serosal incision and is

tied about the cut end of the distal limb of tube so that it projects into the abdominal cavity.

Vaginal Route

Smith and Symmonds[16] at the Mayo Clinic performed partial salpingectomy by the vaginal route in 161 patients. Sixty to 80% of the fimbrial end of the tube is removed and ligation is done. Unsuccessful mobilization of tubes was encountered in two patients, and these were done abdominally. The average hospital stay was 1.4 days including the day of operation. The mean follow-up period was 3.3 years and there was no failure.

Excision of Uterine Cornu

Littig[3], in his extensive review in 1912, concluded that the operation that is likely to give success is excision of all or part of the tube with deep, wedge-shaped excision of the uterine cornu including the pars uterina of the tube. Frequently the whole tube was removed. It has been pointed out[17] that the wedge resection of only the cornual portion of the tube has the technical advantages of: (1) simpler technique, (2) less exposure required, and (3) less interference with broad ligament ovarian blood supply. It is also equally effective. Some surgeons prefer to bury the proximal end of the remaining portion of the tube between the leaves of the broad ligament; but this is considered to be of doubtful value by others and it complicates the procedure. In Garb's review[1] the failure rate was 2.89%.

Other Methods

1. *Cooke Method.* After the divided tubes are ligated separately, the proximal limb is buried by going through the round ligament down between the leaves of the broad ligament. According to Overstreet[17] this method is widely used in the southern part of the United States.
2. *Aldridge Method.* This method[17] is desirable if temporary sterilization is foreseen. The fimbrial end is buried between the leaves of the broad ligament.
3. *Lyons Method.* Electrocoagulation is used to coagulate the tubes in three places 0.5 cm apart[18].

Pratt Operation

Regardless of the approach to the tubes, we think that, as a primary procedure, a thorough curettage of the uterus should be done. With the patient in the lithotomy position, we scrub the vagina with soap and water, paint it with thimerosal (Merthiolate), and then do a curettage (Figure 2). The endometrium is examined by frozen section. If there is no contraindication, we proceed with tubal ligation.

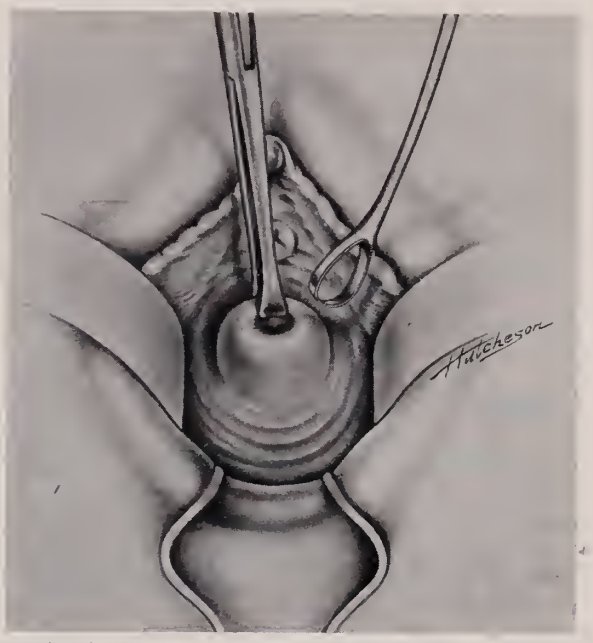

Fig. 2—Thorough, careful dilatation and curettage is always done before ligation procedure, to exclude pathology or pregnancy.

Fig. 3—Transvaginal salpingectomy and ligation are done through transverse incision behind cervix. Cervix is elevated to stretch posterior cul-de-sac. Frequently a small artery at either or both ends of incision must be ligated.

We prefer a transvaginal approach as being quicker and less traumatic to the patient, with simpler convalescence. The cul-de-sac is opened through a transverse incision immediately behind the cervix (Figure 3). A small artery at either end of the transverse incision frequently must be ligated. Two Deaver retractors are utilized through the cul-de-sac to expose the posterior uterine wall. The cervix can be elevated and pushed posteriorly with a tenaculum, abdominal pressure may be utilized, and the fundus is teased down until it presents at the posterior vaginal incision (Figure 4). The uterine end of one tube is grasped with a forceps and crushed (Figure 5-A). A second forceps is placed on the tube a full 3 cm away, and the remainder of the tube is inspected to rule out ectopic pregnancy. A 3 cm segment of tube is excised (Figure 5-B), the outer end is ligated with catgut, and the inner end, which is in the crushing forceps, is wedged from the wall of the uterus (Figure 5-C). The uterine wall is then closed with a mattress suture (Figure 5-D), the distal end of the tube is turned in on itself with an atraumatic stitch, and the tubal mesentery is closed, leaving the end of the distal tubal segment 2 cm or more from the uterus. A similar procedure is carried out for the opposite tube and both excised segments are sent to the pathology laboratory for unequivocal identification. All blood is sponged from the cul-de-sac, and the colpotomy incision is closed in two layers with a running catgut stitch in the peritoneum and a locked catgut stitch in the vaginal mucosa.

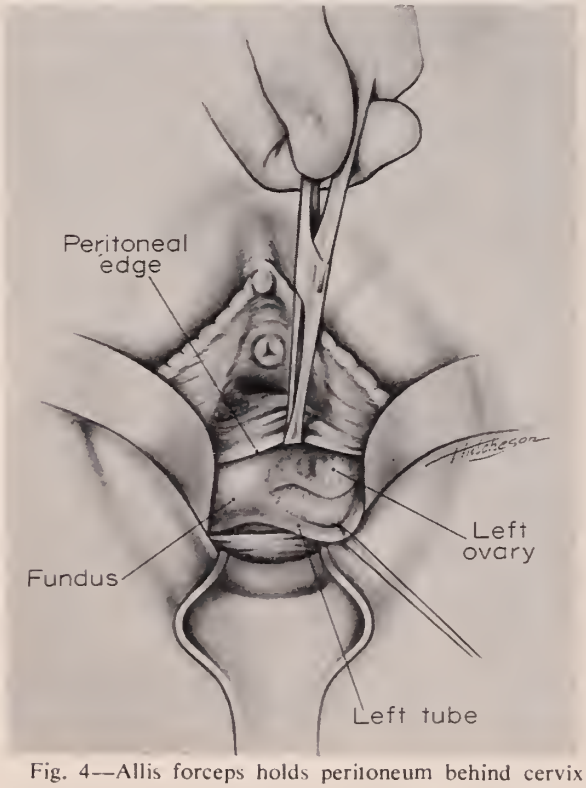

Fig. 4—Allis forceps holds peritoneum behind cervix and two Deaver retractors give adequate exposure to cul-de-sac. Uterine fundus is teased down until it presents at posterior vaginal incision. By moving fundus laterally, either tube and ovary can be exposed.

Laparoscopy

The introduction of the fiber glass bundle into optical equipment in 1964 made possible sterilization through laparoscopy. It is carried out with diathermy coagulation and dissection of about 2 cm of the tubal isthmus. Steptoe[19] emphasized thorough coagulation of the medial stump to prevent fistula formation. A question has been raised[20] as to whether or not resection is necessary, because this step sometimes causes inconvenient bleeding from the region of the stumps. Steptoe found postoperative patency in 10% of 30 women who had coagulation alone. In Steptoe's hands, bleeding is rare and can be controlled easily by the diathermy forceps. Liston and associates[20] had to perform laparotomy in six of their 760 patients to control such bleeding. Bleeding may occur from the inferior epigastric artery and require ligation[19]. The incidence of pregnancy was 0.2% in Steptoe's series, but nine pregnancies occured in Liston and associates' series (five women were pregnant at the time of operation). Two patients had had the round ligament resected instead of the tube. The major objection to the coagulation technique is that no tissue is available for pathologic confirmation that a portion of a tube has actually been blocked.

Complications

A specific operative complication of tubal sterilization is hematoma of the broad ligament. This is rarely reported. Other complications are those inherent in abdominal surgery in general—abdominal bleeding, infection, and cul-de-sac abscess.

The later complications to be mentioned are abnormal uterine bleeding, hydrosalpinx, and torsion of the tubes. Williams and associates[21] reported an incidence of 16.5% for significant abnormal bleeding after tubal ligation in contrast to 5.1% in women not undergoing such a procedure. White[22] reported heavier or more prolonged menses or irregularities in 20.6% of

patients; in Smith and Symmond's[16] series this problem was encountered in 8%.

The late psychologic aspects of sterilization have been given recent attention and reports differ significantly.

Because of difficulties in peritonealization in certain cases of cornual resection, adhesions may form and cause intestinal obstruction.

It was estimated by Paniagua and associates[23] that the mortality for tubal ligation may not exceed one per 10,000 cases when done for other than medical complications of pregnancy and is considerably less than that of childbearing itself.

Route of Approach for Tubal Sterilization

Tubal sterilization cannot be satisfactorily accomplished through the vagina in the immediate postpartum period, but this route can be used for nonpuerperal, interval tubal sterilization. This is frequently done by surgeons who do not wish to remove the uterus at the time of vaginal reparative surgery. It should be emphasized that the overall morbidity and failure rate in tubal sterilization are significantly higher when the vaginal route is used and are highest when it is done at the time of therapeutic abortion. The Madlener method has a 5.3% failure rate when done vaginally at abortion[24]. Cornual resection has a 2.89% failure rate when done through the abdominal wall but 36% when done vaginally at the time of abortion.

The failure rate for the Pomeroy technique is 0.3% when done postpartum abdominally and 5% when done vaginally as an interval procedure.

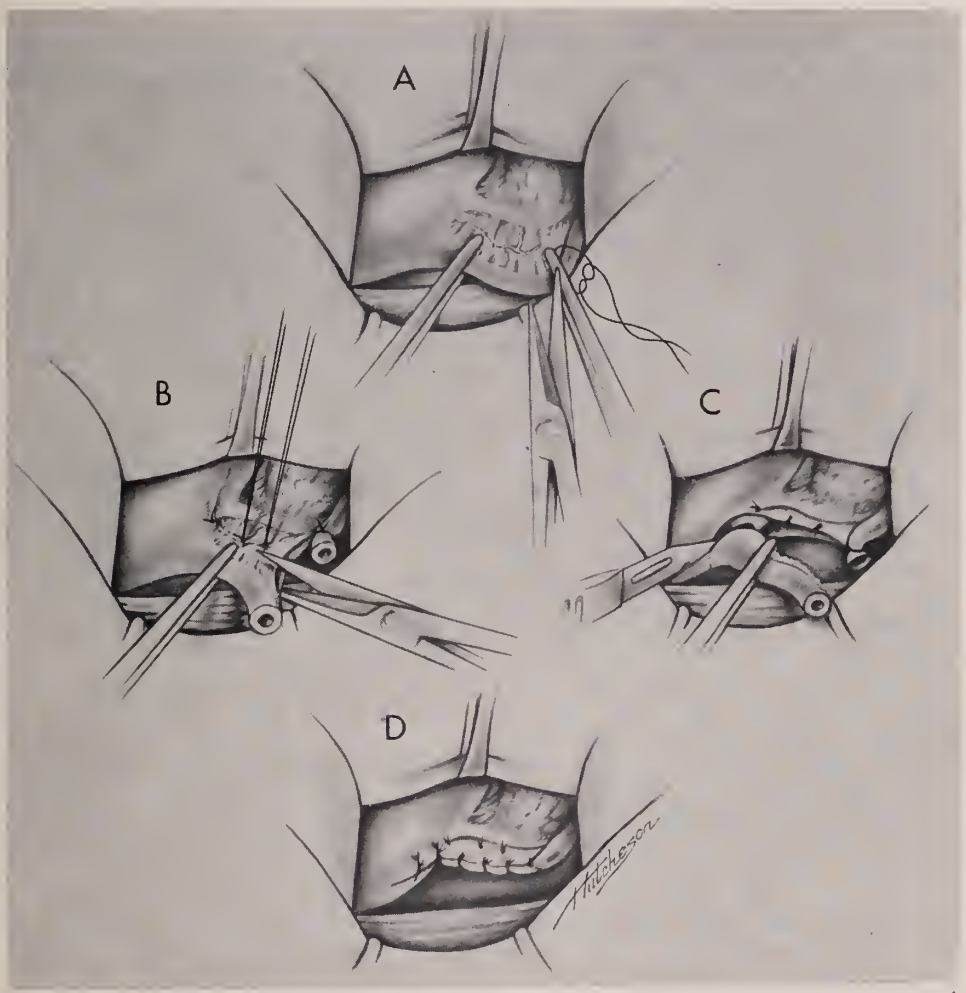

Fig. 5—(A) Tube is held at uterine end and about 3 cm laterally. Distal segment is divided and ligated. (B) Vessels in mesosalpinx must be ligated, as well as larger artery uniformly present in the uterine wall just below tube. (C) Uterine end of tube is wedged from wall of uterus. (D) Uterine wall is closed with mattress suture, distal segment is turned in on itself, and mesosalpinx is closed as well as possible.

For the Pomeroy method the morbidity has been found to be 3.3% when done vaginally[25] but 5% when done abdominally[26]. Among Smith and Symmond's[16] 161 patients having partial salpingectomy done vaginally there were three postoperative pelvic infections and two cases of postoperative bleeding, one from the culdotomy incision and one from a lacerated cervix, presumably from the tenaculum traction. The main difficulties were encountered in those patients who had adhesions from previous pelvic surgery or in recently pregnant women. They advised deferring operation for three to four months after parturition to allow complete uterine involution.

The Cooke and Irving methods are technically difficult if done via the vagina, and the Aldridge procedure cannot be accomplished vaginally.

Transuterine Cornual Coagulation

This operation has been revived several times since first recommended by Froriep in 1850. For some this operation has been tempting because of the speed and ease with which it can be performed. However, it never has become popular in the United States. Some work has been done with it in underdeveloped countries; Pasricha[27] reported doing this operation on 89 women in India. Fifty-three percent of those seen for follow-up examination had patent tubes demonstrable by hysterosalpingography. After a second attempt there were still 34% with patent tubes. Subsequent pregnancies were about 5%. Complications were numerous; salpingitis, severe bleeding, and peritonitis (one with bowel perforation) were reported.

Hysterectomy

Hysterectomy for sterilization alone may be accomplished in the course of vaginal reparative surgery or at the time of cesarean section. Frequently the uterus is removed in the course of reparative surgery without any mention of sterilization, and at present most surgeons consider it an integral part of the operation.

The utilization of cesarean hysterectomy has been a matter of dispute for a few decades. In 1921 Williams[6] described its use for preventing further pregnancies; he considered it the "most efficient method of relieving the existing situation and of effecting definitive sterility." Despite this report, the operation was not generally accepted as an elective sterilization method. It was considered by many as unnecessarily radical, as dangerous because of the greatly increased vascularity, and as difficult because of the uterine size.

In 1,278 cases of elective cesarean hysterectomy collected by Pletsch and Sandberg[28], there were only two maternal deaths (0.16%)—one due to pulmonary embolism and the other to hemorrhage from an unspecified site in a patient with leukemia. On the other hand, there were eight maternal deaths in 265 cases of indicated cesarean hysterectomy. Morbidity was about equal after cesarean hysterectomy and after cesarean section with tubal ligation, ranging from 5 to 30%. Various authors have compared the convalescence after cesarean hysterectomy to that after cesarean section and thought it was "easier," "smoother," "faster," or "shorter" after the former.

Operative complications are mainly excessive bleeding and perforation of the bladder. Up to 58% of the patients in Pletsch and Sandberg's series received blood transfusion, compared to up to 20% in the series of cesarean section and tubal ligation. The relatively high incidence of bladder laceration has been stressed, and in different series its incidence has been from 0.5 to 7.2%. The main postoperative complications are bleeding and hematoma formation, the latter ranging from 1.6% to 4.1% in different series.

Weed pointed out that as many as 14% of patients who had had cesarean section subsequently required a gynecologic surgical procedure, including hysterectomy[28]. Chesterman reported that hysterectomy is performed three times as often in women who have had cesarean section as in those who have been delivered vaginally[28].

In one of the most recent reports, Davis and McKeown[29] reviewed 751 cases at the Chicago Lying-In Hospital. There was no maternal mortality in their series and they stated that the incidence of complications was no greater after cesarean hysterectomy than after ordinary cesarean section when done by competent surgeons.

Summary

A brief history of gynecologic operations for sterilization is presented. The commonly utilized procedures are described and their advantages and disadvantages are stressed. A method of tubal ligation (that of one of us, J. H. P.) is presented. Pathologic identification of segments from both tubes is urged.

Ischemic Electrocardiographic Changes with Reversion

After Removal of Diseased Gallbladders

JOHN W. ANDERSON, M.D.*

It is often difficult to distinguish between the symptoms of coronary artery and biliary tract disease. Either of these entities may present with pain in the right, left or center chest or upper addomen. The pain in either may radiate to the right or left shoulder and arm, and acute episodes may have associated nausea or vomiting. Patients with either disease may be of similar body types and practice similar dietary habits, and both of these conditions are extremely common.

Of course, in some instances, the same patient may at the same time have both biliary tract disease and coronary artery disease, and even the possibility of etiological relationship between the two has been the subject of wide discussion for many years.[1,2]

The problem is made even more difficult by the fact that objective findings, namely electrocardiographic ST-T wave changes characteristic of myocardial ischemia and roentgenologic evidence of gallbladder disease, may coexist[3], in which case it is difficult to decide whether to attack the biliary tract problem surgically or to settle into management of the myocardial ischemia only. Some physicians are somewhat reluctant to advise elective removal of a diseased gallbladder in patients with electrocardiogram evidence of coronary artery disease, feeling that they may be poor surgical risks. This author has in recent years been influenced by the reports of other physicians[4] to advise removal of the gallbladder under such conditions, providing recent acute myocardial ischemia with suspected or proved infarction has been clearly disconfirmed, it being recognized that elective surgery during the first several months after myocardial infarction entails a high risk. It has been impressive to observe the frequency of good clinical results postoperatively, and even more important to observe the number of such cases that demonstrate a reversion of the ST-T waves to normal on postoperative electrocardiograms. The following three cases demonstrate this in varying aged patients:

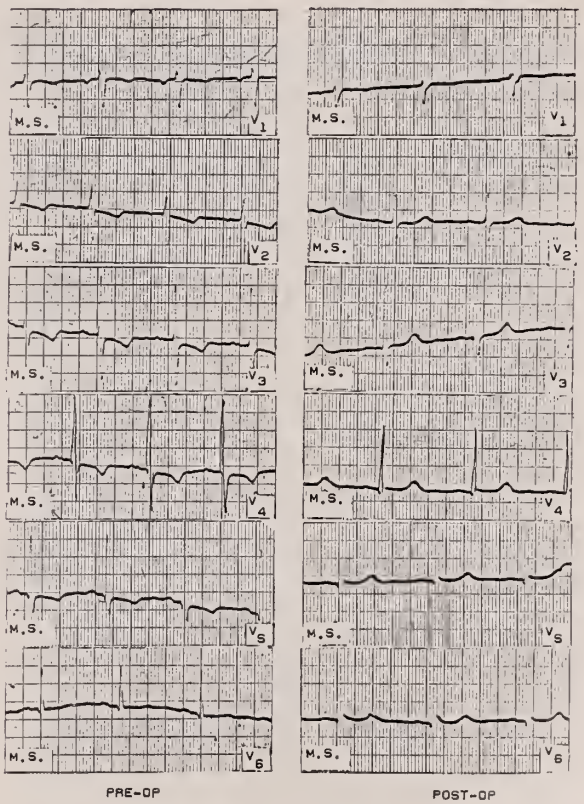

Fig. 1—V_{1-6} Pre-Op and Post-Op.

Case Reports

Case One

A 77-year-old, widowed, white woman was first seen on February 21, 1968, because of episodes of tightness in her chest, at times radiating to both shoulders and arms, usually more severely to the right side. A physical examination was within normal limits. Extensive Xray and laboratory evaluation (to include serum enzymes) was within normal limits with the exception of the electrocardiogram (Figure 1) which demonstrated T wave changes characteristic of myocardial ischemia and the cholecystogram which demonstrated poor concentration of dye and one large gallstone (Figure 2). On the basis of the history and electrocardiogram findings it was thought that the patient might be in a so-called pre-infarction state, and she was hospitalized and treated accordingly. Her symptoms, however, worsened, to include vomiting, abdominal pain and an increase in the right shoulder pain. Because of this, her situation was re-evaluated and cholecystectomy advised. At operation the gallbladder was found to be thick walled from chronic inflammation and to contain one large stone. She withstood the surgery uneventfully. One year later, at which time she said she had been free of symptoms since her cholecystectomy, a repeat electrocardiogram (Figure 1) demonstrated reversion of the T wave changes that had been present on her preoperative electrocardiogram.

Case Two

A 59-year-old, married, white woman was first seen on December 9, 1968, because of episodes of pressure in her upper abdomen, usually after retiring for the night which at times actually delayed her being able to go to sleep. She also noted that her heart would pound during these episodes. A physical examination was within normal limits. Extensive Xray and laboratory evaluation (to include serum enzymes) was all within normal limits except for the electrocardiogram which demonstrated ST-T wave changes characteristic of myocardial ischemia (Fig. 3) and the cholecystogram which demonstrated numerous small gallstones (Fig. 4). The patient was placed on a treatment regime used for coronary insufficiency but without relief of her symptoms. She was advised to have a cholecystectomy which was performed six weeks after her first examination. At operation the gallbladder was found to be thick walled from chronic inflammation and to contain numerous small stones. Six months later, she had been free of symptoms since recovery from her cholecystectomy and a repeat electrocardiogram demonstrated reversion of the ST-T wave changes that had been noted on her preoperative electrocardiogram. Continued follow-up since then has revealed these normal conditions to persist.

Case Three

A 42-year-old, married, white woman was first seen on February 13, 1970, because of discomfort in her right abdomen. Numerous members of her family had been victims of cardiovascular disease. A physical ex-

Fig. 2—Xray (Case 1)—cholecystogram.

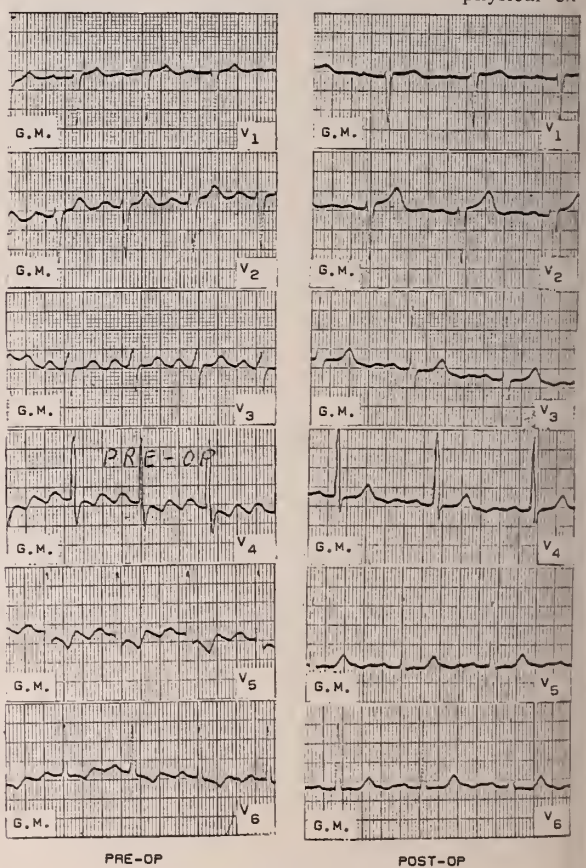

Fig. 3—V_{1-6} Pre-Op and Post-Op

amination was within normal limits. Extensive Xray and laboratory evaluation (to include serum enzymes) was within normal limits except for the electrocardiogram (Figure 5) which demonstrated T wave changes characteristic of myocardial ischemia and the cholecystogram which demonstrated a large gallstone (Figure 6). It was thought that the patient's signs and symptoms were related to her gallbladder disease so she was advised to have a cholecystectomy which was performed two weeks after her first examination. At operation the gallbladder was found to be thick walled from chronic inflammation and to contain one large stone. Five weeks later, she was free of her previous symptoms and a repeat electrocardiogram (Figure 5) demonstrated reversion of the ST-T wave changes that had been present preoperatively.

Comment

Electrocardiographic ST-T wave changes characteristic of myocardial ischemia from coronary artery disease have been found in patients with pancreatic disorders, hemorrhage in the upper gastrointestinal tract, metabolic disturbances, intracranial hemorrhage and infracardiac truncal vagotomy as well as biliary tract disease. T wave changes following subarachnoid hemorrhage have been attributed to vagal stimulation at the level

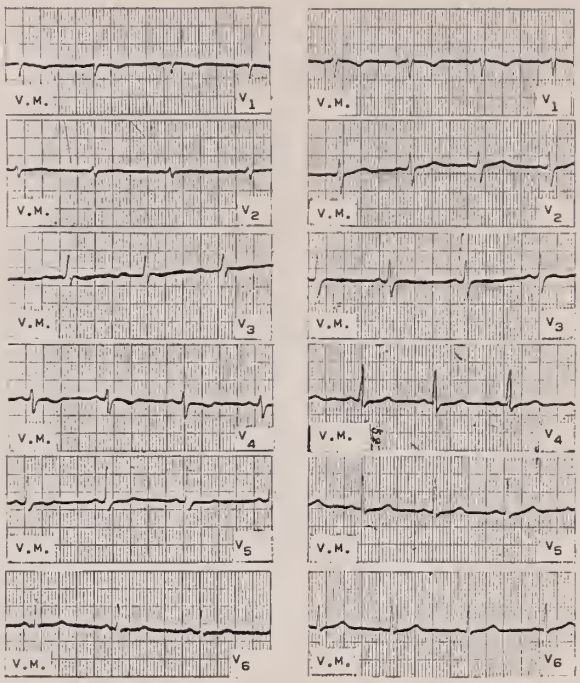

Fig. 5—V_{1-6} Pre-Op and Post-Op.

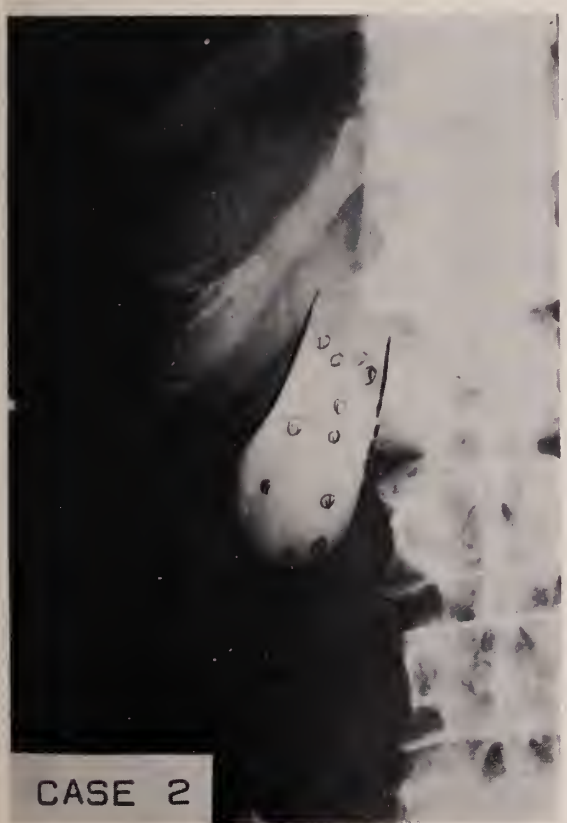

Fig. 4—Xray (Case 2)—cholecystogram

Fig. 6—Xray (Case 3)—cholecystogram

of the brain.[5] Animal experiments with paraffin cerebral embolism have shown abnormal T wave changes which were prevented by prior transection of the vagus.[6] In 1937 Manning et al.[7] reported the occurrence of myocardial damage in animals, with the presence of negative T waves, due to prolonged stimulation of the vagus nerve. This phenomenon was prevented by atropine and accentuated by physostigmine.[7] Frieden has postulated that the ST-T wave changes that may accompany biliary tract disease result from vagally mediated reflex coronary vasoconstriction via retrograde vagal conduction and central autonomic stimulation.[8]

It would appear from the work of the authors that biliary tract disease may in some patients exert a vagal, possibly deleterious, effect on the heart. Other authors have argued that an improved electrocardiogram after a cholecystectomy was merely an unrelated coincidence in the natural life history of coronary artery disease. However, it seems likely on the basis of both experimental and clinical observations that the relationship between gallbladder disease and myocardial ischemia is more than happenstance. Furthermore, in order to enhance the management of both conditions, it is probably advisable to perform Xray studies of the biliary tract in all patients with suspected or proved coronary artery disease and to perform electrocardiographic studies in all patients with suspected or proved biliary tract disease. Those found to have both diseases can be expected in some cases to show reversion of their electrocardiograms to normal after judicious and timely cholecystectomy, and, furthermore, to be some relieved of the dangers inherent in the complications of both biliary tract and coronary

"Mexican Pilgrimage"

Dr. Robert L. Wilder, Minneapolis pediatrician, stated that the cover painting is his impression of the annual pilgrimage in February of the Mexicans of the central area of Mexico to the Shrine of the Virgin at San Juan de los Lagos, some miles east of Guadalajara.

Dr. Wilder's art training began after his retirement in 1957 with instructions obtained at the Minneapolis Art Institute, Minnetonka Center of Art and Education and the Instituto Allende Mexico.

He is a Fellow of the American Academy of Pediatrics, a former Clinical Associate Professor of Pediatrics of the University of Minnesota, and has memberships in the American Physicians' Art Association and the Society of Minnesota Sculptors.

Radiation and Leukemia Mortality

Proof or Spoof

DONALD E. BARBER, PH. D.*

It has been more than a year since statements concerning relationships between radiation exposure and leukemia began to appear in the news media in the Minneapolis-St. Paul area. These statements were made in conjunction with expressions of concern over construction of nuclear powered generating stations in Minnesota. The implication of the statements is that exposures to low levels of radioactivity released to the air and water will result in increased leukemia mortality in our population, particularly in young people.

Radiation doses of greater than 100 rads[1] are known to induce acute leukemia or chronic myelogenous leukemia, but *not* lymphocytic leukemia.[2,3] Findings of the Atomic Bomb Casualty Commission . . . "indicate that the leukemogenic effect of radiation was greater in children exposed to the bomb than in older persons. Among those under 10 years of age, the leukemia rate was 26 times higher if exposure was within 1500 meters of the hypocenter than when it was beyond that distance. In the next age group, 10 to 19 years of age at the time of exposure, the corresponding increase was 18 fold."[4]

There is no question that acute, high doses of radiation can induce leukemia, particularly in children. However, the effects of exposure to high doses accumulated over a long period of time and the effects of low doses remain open to question. For example, of 420 human cases involving radium ingestion there have been no proven cases of leukemia 30 to 50 years after radium was taken into the body in quantities as high as 40 uCi.[5] With each passing year it becomes increasingly difficult to support the premise that any amount of radiation exposure involves some risk (however small) of developing leukemia.

The Columbia River

Fadeley[6] in 1965 reported an increased mortality rate for cancer, including leukemia, among residents near the south bank of the Columbia River which receives radioactivity from a large national laboratory.

His suggestion of a possible causal relationship between radioactivity and his observed higher cancer mortality rate would be important if his observations could be confirmed. However, a reappraisal of his report by Bailar and Young[7] presented evidence to refute his suggestions. The solid lines in Figure 1 show the leukemia mortality on the south side of the Columbia River (Oregon) and on the north side of the river (Washington). The dashed line is the nationwide leukemia mortality for the white population. Fadeley considered only the leukemia mortality on the Oregon side of the river. As the figure shows, leukemia mortality is climbing on that side of the river, but there appears to be a trend toward leveling off similar to that in the U.S. white population in the early fifties.

If one wishes to argue about the differences between the U.S. and the river county curves in this figure, it is interesting to note that the mortality

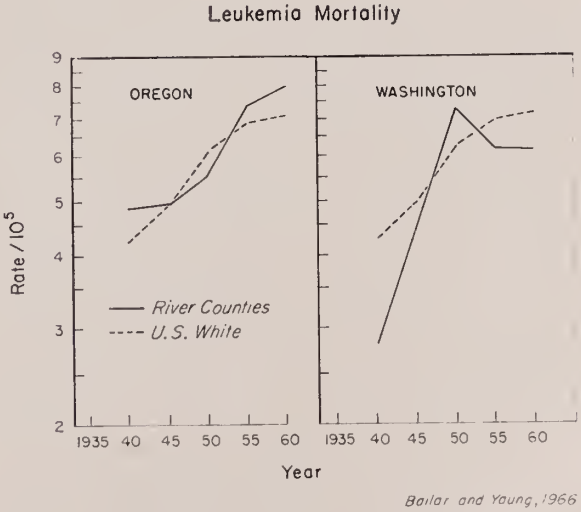

Fig. 1—Leukemia mortality on the Columbia River, 1940-60.

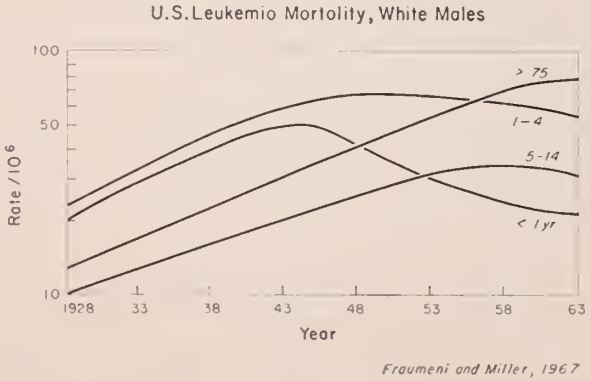
*School of Public Health, University of Minnesota, Minneapolis, Minnesota.

rate, even on the Oregon side of the river, prior to major operations at the national laboratory, about 1945, was higher than in the U.S. white population. After the laboratory went into operation the leukemia mortality along the Oregon side of the river stayed below that for the mortality in the U.S. white population until the early 50s. But the differences between the two curves in the figure are not significant because wide variations are found from year to year in leukemia mortality data from whatever source. On the basis of the Oregon data alone, it is difficult to see how one can conclude that radioactivity from the laboratory influenced the leukemia mortality on the south side of the Columbia River.

Leukemia mortality in the counties on the north side of the Columbia River presents an entirely different picture but one which makes it even more difficult to justify any causal relationship between the radioactivity in the Columbia River and the leukemia mortality in residents downriver from the source of that activity. If one insists that the differences in the figure are significant and related to radioactivity, one is led to the conclusion that the radioactivity from the laboratory has been of benefit to residents on the Washington side of the river.

Nationwide Leukemia Mortality

Figure 2 shows the nationwide leukemia mortality rate for white males for a number of age groups.[8] Except for the age groups under one year and over 75, the curves for all age groups are similar in shape, but mortality rates in any five year period since 1928 are highest for age groups one to four and 45 to 54 (the latter group not shown on this figure) until about 1953 when the rate in the age group over 75 overtook the rates in all other groups. It is interesting to note from this figure that leveling off of leukemia mortality and declining mortality in the younger age groups, the age groups of most concern, one to four and five to 14, occur during the very years when radioactivity from fallout was being contributed to our environment at the greatest rate.



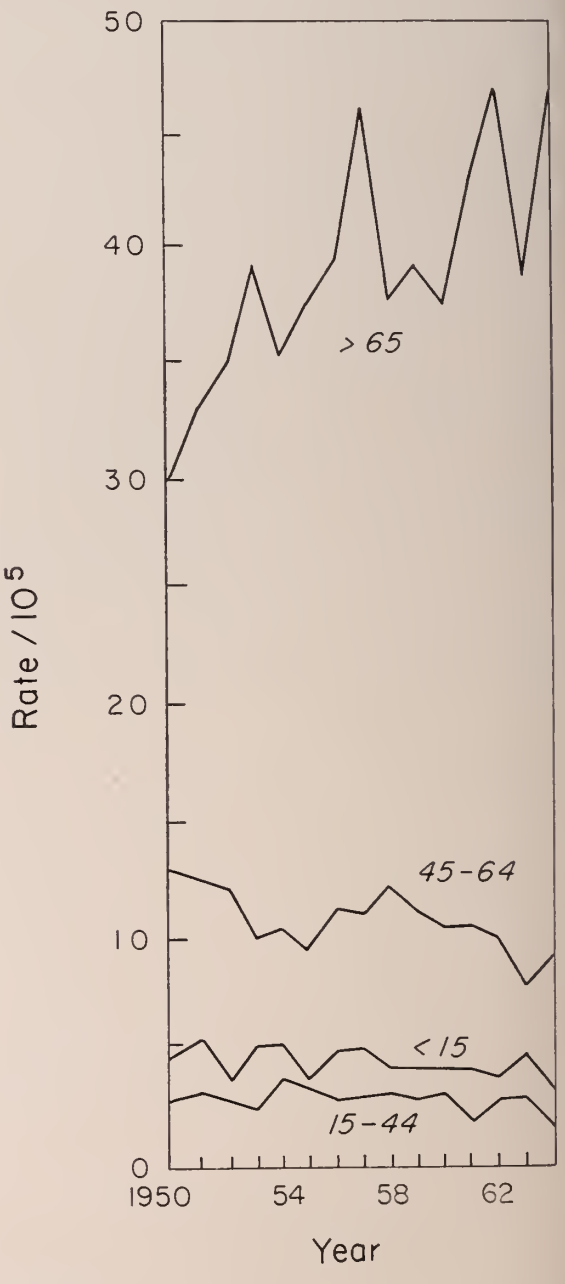


Fig. 2—Nationwide leukemia mortality.

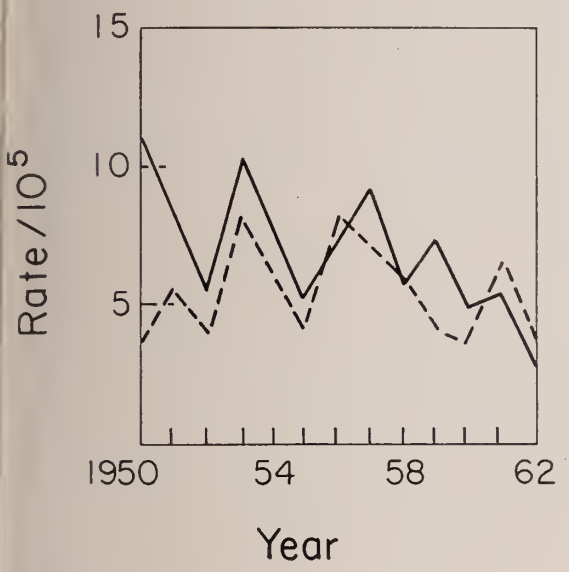
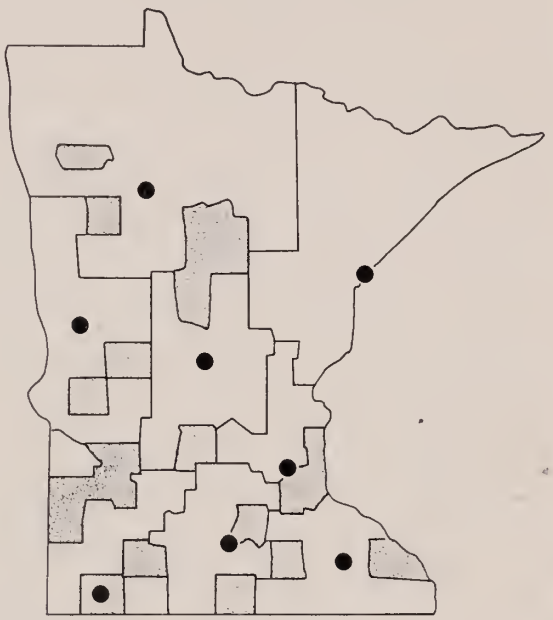


From McCullough, et. al., 1967.

Fig. 3—Minnesota leukemia mortality.

Minnesota Leukemia Mortality

From 1929 to 1951 Minnesota has had either the highest or the second highest leukemia mortality of any state in the country. Minnesota was surpassed by Vermont in the years 1949 to 1951 and by the District of Columbia in the years 1939 to 1941.[9] Figure 3 shows the Minnesota leukemia mortality rate for the years 1950 to 1964 for four different age groups. The fluctuations are huge for the age groups over 65. For ages zero to four, we see in Figure 4 a declining trend in leukemia mortality among males; but no trend is apparent in females.



From McCullough, et. al., 1967.

Fig. 4—Minnesota leukemia mortality, ages zero to four.

Highest Mortality with Lowest Fallout Exposure

In some counties in Minnesota the average, annual, age-adjusted leukemia mortality rate for the years 1950 to 1964 varied significantly from the average state rate for that same period.[10] The highest rate occurred in Wabasha County in southeastern Minnesota where exposure to fallout is low by comparison with northern Minnesota.[11] Concentrations of strontium-90 in milk in northern Minnesota have been one-and-a-half to two times those in southern Minnesota since 1962.[11] A similar picture occurs for cesium-137 concentrations in milk.[12]

Figure 5 shows the state health districts, milk sampling stations and counties (gray areas) in the state with highest age-adjusted leukemia mortality for the years 1950 to 1964.[10,12] The important feature of this figure is the relatively higher leukemia mortality in the southern part of the state where radioactive contamination of milk from fallout is lower than in the northern part of the state.[7,10] Duluth, however, did not have higher rates compared with St. Louis County.[10]

From McCullough, et. al., 1967 and Radiological Health Data and Reports, 1968.

Fig. 5—Minnesota health districts, milk sample stations (●) and counties (gray areas) with highest age-adjusted leukemia mortality, 1950-64.

Radioactivity of Drinking Water

Radioactivity entering the body commonly does so by way of food, except where unusually high concentrations occur in water. Typical concentrations of Radium-226 in *city drinking water* range from 0.01 to 0.14 pCi/1. But concentrations in *rural drinking water* range from 0.03 to 2.3 pCi/1.[13] Radium-226 concentrations in rural drinking water, therefore, are from three to 20 times concentrations for urban supplies. Like strontium-90, radium is a bone seeker and bone is a critical tissue from the viewpoint of leukemia production. If the quality factor for alpha rays from radium is taken to be 10, then Radium-226 contributes a substantial fraction, from seven to 30 per cent, of the total background dose to bone. So, if either background radiation or fallout is responsible for increasing leukemia mortal-

ity in the population and if population density is a factor contributing to the correct interpretation of leukemia mortality data, it is difficult to reconcile the distribution of the leukemia mortality statistics in Minnesota with radiation exposure.

Discussion

The nationwide picture of leukemia shows that the mortality rate in all age groups except for those over 75 has leveled off and is decreasing. We know that dose rates vary from time to time from fallout and other sources of radioactivity and radiation, but the total or integral dose to which an individual is exposed can only grow larger with the passage of time. If the assumption is true that there is no threshold for radiation induced leukemia, then the nationwide mortality rate data are inconsistent with that hypothesis. Apparently the years of highest radiation exposure, 1945-63, during which the greatest amount of radioactive material was ingested have not influenced the trends observed in the nationwide leukemia mortality statistics.

Dose rates, and therefore doses, in the years 1958-1959 and 1962-1963 from fallout would have been highest for the fetus in the first trimester and infants. Consequently, leukemia mortality would be expected to increase five to ten years later or about 1963 to 1969 and 1967 to 1973. However, the mortality statistics for these periods do not reflect evidence of a special sensitivity of the young to radioactivity from fallout.

A legitimate question is: even on the assumption that there is no threshold for radiation induced leukemia, would one expect to see manifestations of this fact in our leukemia mortality statistics? According to Hempelmann the risk of developing leukemia is about one case per million people per rad absorbed per year.[14] If this risk statement is true, then over a period of 20 years we would anticipate an increase in the leukemia rate produced by background radiation alone of at least two cases per million. We would certainly not expect a decline in the mortality rate unless improvements in radiation exposure had been made and in fact radiation exposure had contributed to the increase in leukemia mortality over the years. Fraumeni and Miller have suggested that improvements in medical x-ray exposure may explain the downturn in leukemia mortality rates in the United States during the late 50's and early 60's.[8] However, if the assumption is correct that the risk of inducing leukemia with radiation is about one case per million per rad per year, then the downturn rates observed by Miller and Fraumeni are much too large.

It is an interesting coincidence that nationwide leukemia mortality rates began to level off during the years 1943 to 1948. Fallout has been with us since that period. The years 1945 to 1949 were years in which a tremendous surge in the use of antibiotics occurred. DDT was first used about 1944 and was used extensively until the early fifties. Thereafter new insecticides and artificial fertilizers were widely used. All of these activities correlate with observed trends shown in the nationwide leukemia mortality data. The possibility that these agents influenced leukemia mortality seems as amenable to proof as the suggestion that reduction in medical exposure is responsible for a downturn rate in the leukemia mortality data. Perhaps the change in leukemia mortality has occurred in spite of radiation rather than because of it.

Conclusions

I have pointed out, perhaps facetiously, a number of observations which are inconsistent with an hypothesis that low levels of radiation exposure increase the leukemia mortality rate. These observations are:

1. The general pattern of nationwide leukemia mortality rates during the years 1923 to 1963 has changed.
2. The relative concentrations of radium in drinking water supplies available to urban and rural populations, suggest an inverse relation between exposure and leukemia mortality.
3. Leukemia appears to be more prevalent in southern Minnesota than in northern Minnesota, but the exposure to fallout activity through the milk-food chain appears to be lower in the south than in the north.
4. There is no evidence that persons living downstream from the national laboratory on the Columbia River had an excess risk of death from leukemia by virtue of their location, presumably from the run off from a large national laboratory.
5. If exposure to environmental factors, including radiation, is responsible for leukemia, exposure has either stabilized or decreased during the period 1940-1963.

Human data prove that doses of 100 rads or more received in a short period of time increase the risk of developing leukemia. On the other hand, attempts to establish a causal relationship between leukemia mortality and lesser doses, particularly those accumulated over a long period of time, appear to involve more spoof than proof. Miller expresses my feeling perhaps better than I could express it myself when he writes, "The total number of delayed organic effects of atomic irradiation among Japanese children has been small. The most prevalent late effect, difficult to document, is the fear of late effects, a most unfortunate circumstance in view of the small risk indicated by the results to date."[4]

Everybody's family doctor was remarkably clever, and was understood to have immeasurable skill in the management and training of the most skittish or vicious diseases. The evidence of his cleverness was of the higher intuitive order, lying in his lady 'patients' immovable conviction, and was unassailable by any objection except that their intuitions were opposed by others equally strong; each lady who saw medical truth in "the strengthening treatment": regarding "the lowering system" as medical perdition. For the heroic times of copious bleeding and blistering had not yet departed, still less the times of thorough-going theory, when disease in general was called by some bad name, and treated accordingly without shilly-shally—as if, for example, it were to be called insurrection, which must not be fired on with blank-cartridge, but have its blood drawn at once. The strentheners and the lowerers were all "clever" men in somebody's opinion, which is really as much as can be said for any living talents.*

*George Eliot: Middlemarch, Book 11 Chapter 15. 1871-1872. (describing the family physician of 1830.)

Primary Pulmonary Fibroma

JOHN J. SAUK, JR., D.D.S., M.S.D.*, MARIO PLIEGO, M.D.† AND
W. ROBERT ANDERSON, M.D.‡

THE PRIMARY PULMONARY fibroma is among the rare group of primary mesenchymal tumors of the lung. The entity, however, must be distinguished from its sister mesenchymal neoplasms, the leiomyoma, the neurofibroma, and the fibrous mesothelioma.

D'Aste,[1] in 1955, documented only 15 such lesions, classified as pulmonary fibroma from 1926 to 1952, and gives Sauerbruch credit for the first reported case in modern medical literature. Other cases documented since D'Aste's paper[2-6] have further alluded to the entity, and have defined it more completely with the use of histochemical stains, and the identification of possible pleural origin, separating the fibrous mesothelioma as a separate and discrete lesion.

Case Report

The patient, an 84-year-old Caucasian male, first presented in 1964 with a respiratory distress syndrome. Radiologic examination revealed a large mass in the right lower lobe of the lung. The patient refused any surgical or therapeutic intervention, but was followed regularly at Hennepin County General Hospital.

Radiologic Reports

The first radiograph taken at Hennepin County General Hospital March 16, 1964, an anteroposterior view of the chest, revealed a large multilobulated, smoothly outlined, dense, homogeneous shadow lying in the lower half of the right lower lobe. The mass was within the lung parenchyma, and some portion of it appeared to be in close proximity to the right pleural space. The lesion at that time measured 12 x 7 cm, and presented several eccentric calcifications within it and other small calcifications situated at the upper lobes, probably due to calcified granuloma. The heart was enlarged, left ventricular predominance. The aorta was calcified. There was a fracture deformity of the fifth right rib.

Subsequent radiographs done in 1965, 1966, and 1967, revealed no great change in the size and shape of the tumor. The last radiographs taken were in June, 1969, in which most of the tumor was obliterated by fluid, the patient being in congestive heart failure with enlargement of the heart, pulmonary vascular congestion and bilateral

Fig. 1—Anteroposterior and lateral radiographs taken in 1964 showing a radiopague mass in the lower right lobe of the right lung.

pleural effusion.

In June of 1969 the patient was admitted with severe respiratory distress and a clinical diagnosis of bronchial pneumonia and congestive heart failure. His clinical course became terminal only days after admission. The body was presented for autopsy the day of death.

Autopsy Report

The autopsy revealed a well developed, well nourished 84-year-old Caucasian weighing approximately 150 pounds and showing no gross physical external abnormalities.

The heart weighed 700 grams. The right ventricle was 5 mm thick; the intraventricular septum, 7 mm thick; and the left verticle 20 mm thick. All valves were normal; the coronary ostia and the coronary arteries were patent. Organ diagnosis was that of cardiomegaly secondary to hypertension and cor pulmonale.

The lungs weighed 2250 grams combined. The pleural surfaces were diffusely anthracotically pigmented. Crepitus was markedly decreased. The parenchyma was severely congested with voluminous amounts of fluid; small nodular consolidations (bronchial pneumonia) were located throughout the parenchyma.

A large mass, 10 cm x 10 cm x 5 cm, was present in the right lower lobe of the right lung but did not involve either the viseral or the parietal pleura. On cut section it was yellow-gray in color and showed central necrosis. The trachea and main stem bronchi were not involved but showed a mucopurulent exudate.

The remainder of the gross autopsy was noncontributive.

Microscopic Examination

Microscopic examination of the lung revealed a tumerous mass, showing central necrosis. The viable cells showed a spindled cell pattern. The nuclei of the mass were slightly hyperchromatic but regular in size. A high degree of collagen formation was present intracellularly. Interlacing bundles typify the general tumor pattern. Mitoses were rare within the tumor and the mass appeared to be microscopically free from the pleura and bronchi.

Diagnosis

Intraparenchymal Primary Pulmonary Fibroma. (Low Grade Fibrosarcoma?)

Discussion

The problem of delineation of pulmonary fibromas from their sister neoplasms has resulted in confusion, especially with regard to their incidence, as many reports refer to the origin of the entity lying within the thoracic wall, the mediastinum, or the visceral pleura.[7-13] It is the belief of these authors and others[2-4] that the clinicopathologic term for those lesions, arising in the

Fig. 2—Anteroposterior and lateral radiographs showing the unchanged course of the lesion after three years.

interlobar fissures, parietal and visceral pleura, should be fibrous mesotheliomas.

Other diagnoses that often tend to confuse the label of pulmonary fibroma are the low-grade pulmonary fibrosarcoma, and various inflammatory fibroses discovered within the lung. The criteria to delineate low-grade fibrosarcoma have been: cellularity of the lesion, the amount of desmoplasia present, and the duration of the lesion. Mitoses in both instances have been considered rare, and cellular atypia is not present in well differentiated cases of the former. The duration of the lesions in both cases is relatively the same, being long, and metastasis does not occur in either. Therefore, lesions which have been highly cellular and have had little to no desmoplasia have been considered to be fibrosarcomas. It must be noted that even these criteria vary from microscopist to microscopist, and in some cases the final diagnosis is still a question of academic preference.

Inflammatory fibroses also present a problem in diagnosis, especially when biopsy is the method.

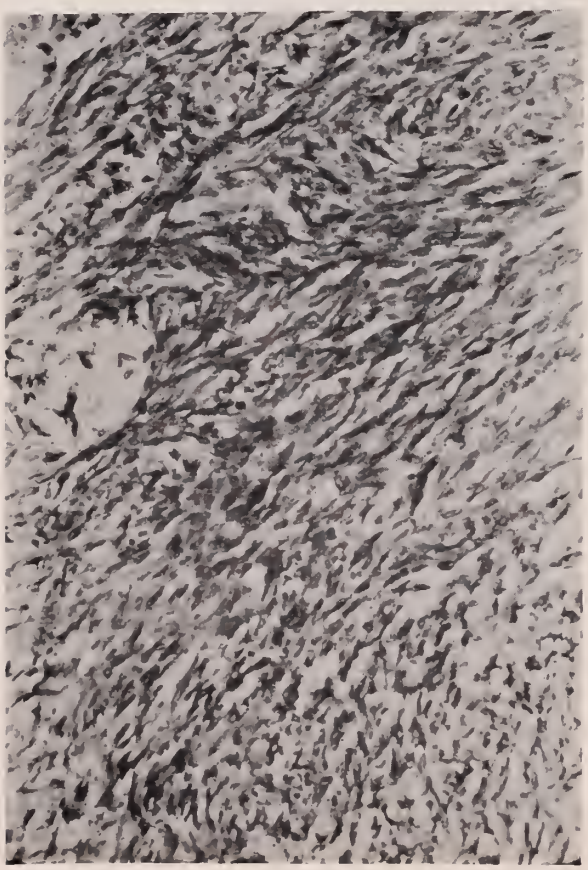

Fig. 3—High dry view (450X) showing the regular cellularity, interlacing pattern of cells, and desmoplasia.

However, with an inflammatory history, endothelial proliferation, and the presence or absence of inflammatory cells a reasonable diagnosis of neoplasia versus inflammation can usually be made. In spite of such guidelines, reports of pulmonary fibromas referred to as "hamartoblastomas" have in the same text described these entities both as neoplastic and "granuloma-like."[13]

Classically two types of pulmonary fibromas have been described, those occurring in the endobronchial tree, or an extension thereof, and those located completely within the parenchyma of the lung.[1,3,4] Likewise fibrosarcomas of the lung are also divided into those of the parenchyma and those of the endobronchial tree.

Fibromas of the endobronchial tree usually lend themselves to bronchoscopic examination and are visualized as pinkish-gray polypoid lesions. Those within the parenchyma proper are first observed on radiologic examination of the chest and present as solitary, circumscribed pulmonary densities. Differential diagnosis in both cases is usually quite broad because of the rarity of the lesion; an unexpected diagnosis is elicited by thoracotomy or by autopsy.

Review of the literature and examination of the clinical data reveal that the average age distribution for pulmonary fibromas is between 24 and 84 years of age, with an average 55 years.

The sex ratio is 65% males and 35% females. In all cases the racial distribution was limited to the Caucasian race.

The duration of symptoms have ranged from a period of one month to five years, with an average of two years. Presenting symptoms have been shortness of breath and, when the lesion has been exceedingly large, cor pulmonale with associated congestive heart failure.

The location of lesions has been evenly distributed both within the parenchyma and within the endobronchial tree. The lobar location has been 40 percent in the right lower lobe and 40 percent in the left lower lobe, with the rest located in the remaining lobes.

Treatment in all cases has been best achieved by surgical removal, usually local excision. The prognosis has been excellent unless a large amount of lung parenchyma has been previously destroyed by infectious or neoplastic processes.

Summary

In summary a rare mesenchymal neoplasm has been discussed with regard to sex incidence, location, classification, and therapy. This rare pulmonary neoplasm, pulmonary fibroma, has been documented in an 84-year-old male Caucasian and has served as a model for discussion and an addition to the archives of the world literature.

It's the Law

Honest Misdiagnosis Held Not To Be Malpractice

A five-year-old child had vomiting and stomach-ache with pain in the lower right side of her abdomen, and a temperature of 101. The white blood cell count was 5,000. The child was examined by a physician who found red tonsils and made the diagnosis of tonsillitis. He gave the parents medication for the child and sent her home.

On the seventh day of her illness, the child was still complaining of stomach pain. She was admitted to the hospital and the white blood cell count was 18,000. Xrays were made, and surgery was performed. This disclosed a ruptured appendix with peritonitis. There was a complicated hospital course with a bowel obstruction, much wound drainage and a penicillin reaction.

The child's father sued the physician for malpractice. The courts held that a physician does not insure correctness of diagnosis. Evidence had been presented that the patient received a thorough examination conducted with diligence and skill. The court held that the physician was not negligent, hence, no malpractice and the suit was dismissed.

Prostatic Urethral Calculus

GERALD W. IRELAND, M.D.*, LLOYD C. GILMAN, M.D.* AND
ALEXANDER S. CASS, M.D.*

CALCULI PRESENTING in the urethra are not uncommon, but a large calculus in the prostatic urethra without a previous prostatectomy is rare and is reported below.

Case Report

A 39-year-old white male was born with a lumbar myelomeningocele which was repaired in the newborn period. The patient had had no follow-up since and had been incontinent of urine and feces for which he has worn diapers all his life. He lived on a farm with his parents and had no education which resulted in poor speech and illiteracy. He also has bilateral clubbed feet but was fully ambulatory.

Examination

He was admitted to our hospital on December 18, 1968, acutely ill with retention of urine, urinary tract infection and renal failure. The urine cultured Proteus mirabilis over 100,000 cols/ml. Other laboratory results were Hb 17.4 gm%, Na 119, Cl 97, K 8mEq/1 and blood urea 108 mg%. A rectal examination revealed an enlarged and stony hard prostate. A urethral catheter could not be passed due to obstruction in the prostatic region. A KUB x-ray revealed two stones in the pelvis (Figure 1A), and a retrograde urethrogram demonstrated the larger stone to be in the prostatic urethra. (Figure 1B) After correction of the hyperkalemia and dehydration a suprapubic cystostomy was performed on December 19, 1968, with removal of the 6 cms diameter stone (117 gms) (Figure 2) from the prostatic urethra and a smaller stone (17 gms) from the bladder.

Appropriate intravenous fluids and antibiotics were given postoperatively, and his condition improved although the postoperative course was complicated by a gastrointestinal hemorrhage requiring blood transfusion. The blood urea fell to 34 mgm%, and a creatinine clearance was 34 liters/day/1.73 $M.^2$ An infusion excretory urogram (Figure 3A) and retrograde pyelograms revealed bilateral hydronephrosis and hydroureters with reduced renal parenchyma.

A cystogram (Figure 3B) and cystoscopy revealed a neurogenic bladder which allowed urinary incontinence when the suprapubic tube was clamped.

On January 28, 1969, a urinary diversion was performed consisting of an isolated segment of transverse colon with the open ends anastomosed to the pelves of

Fig. 1A—KUB x-ray examination of the pelvis revealing two stones.

Fig. 1B—Retrograde urethrogram demonstrates larger stone to be in prostatic urethra.

*Department of Urology, St. Paul-Ramsey Hospital, St. Paul, Minnesota.

he kidneys and the mid-portion brought to the skin as an ostomy. Urine culture from each kidney at operation revealed Pseudomonas over 100,000 cols/ml.

Postoperative Course

The postoperative course demonstrated some improvement of renal function, and the patient was discharged on February 25, 1969, with a blood urea of 35 mgm% and a creatinine clearance of 47 liters/day/1.73 M^2, and serum Na 140, K 4.1, CO_2 21, Cl 104, Meq/L. The stool cultured Pseudomonas over 100,000 cols/ml.

Discussion

A prostatic urethral calculus arises either from within the prostate gland (endogenous), within pockets or diverticula in the posterior urethra or reached the urethra from the kidney, ureter or bladder (exogenous).[1]

In our patient the calculus was thought to be exogenous and arose in the neurogenic bladder associated with his myelomeningocele. The calculus migrated to the posterior urethra where it enlarged to greatly expand the prostatic urethra and compress the prostate tissue.

Giant prostatic urethral calculi are rare, and 16 cases have been described[1-12]; the actual weight (45, 58, 80, 99, 327, 390, 780 gms.) and the size (two to 10 cms. longest dimension) are recorded in 10 of these cases. The calculus in our patient weighed 117 gms. and measured 6x5x5 cms which allows it to be designated as a giant prostatic urethral calculus.

A giant prostatic urethral calculus would, presumably, completely obstruct the flow of urine through the urethra. Grooves were present on the posterior aspect of the calculus, corresponding to the urethral crest and verumontanum, which would possibly allow the passage of some urine past the calculus. Similar grooves have been recorded in two cases of giant prostatic urethral calculus.[1,11]

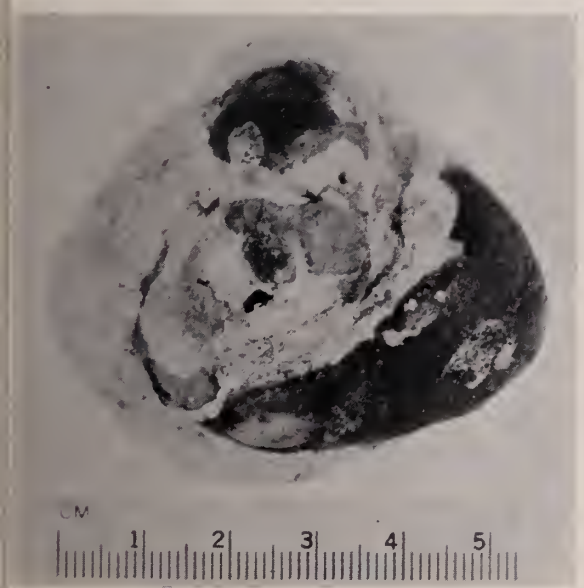

Fig. 2—Calculus removed from the prostatic urethra; posterior aspect shown with grooves visible.

Summary

A prostatic urethral calculus, weighing 117

Fig. 3A—An infusion excretory urogram revealing bilateral hydronephrosis.

Fig. 3B—A cystogram via the suprapubic tube demonstrated a neurogenic bladder with diverticula and left ureteral reflux with hydronephrosis and hydroureter.

gms and measuring 6x5x5 cms was found in a 39-year-old male with myelomeningocele who presented with retention of urine, urinary infection and renal failure.

Letter to the Editor

Dear Editor:

I was pleased to find in the February, 1972, MINNESOTA MEDICINE* a reference to a charming fantasy. Dr. Charles Jarvis introduces his article *"Osmolality"* by saying, "Some years ago H. L. Gold wrote a little story about a man who got into trouble with the elves of a certain lake. As punishment the elves decreed that water would actively stay away from him. Since he was at the lake primarily to fish, but wanted also to bathe and drink, the results of the decree proved frustrating to the hero and amusing to the reader."

The story is "Trouble With Water" by L. E. Gold (Dr. Jarvis' memory misled him slightly—H. L. Gold is a younger writer). It appeared in the late John W. Campbell's magazine, *Unknown Worlds*, and was reprinted in the anthology *From Unknown Worlds* (New York, 1948).

As the slogan of the Los Angeles Science Fantasy Society puts it, "Death does not release you" (from membership). Dr. Jarvis has long since ceased to be active as a fan of fantasy-literature, but he was once well known in the field and clearly remains fond of it. Redd Boggs, in his article on the growth of Minnesota science fiction fandom ("Giants in Those Days," Part I, which I printed in *NeoLithic* 19, October 1961) described the young Charles W. Jarvis, "who had become one of the most prolific and talked-about letterhacks in "Brass Tacks" [the letter column of *Astounding Science Fiction, Unknown World's* older and more successful sister magazine]. Jarvis dabbled briefly in fandom—he mentioned receiving news about Grey Lensman from the fan magazines in a letter published October 1939—and in the thirties attended a number of meetings of the Minneapolis Fantasy Society. One of the few old-time fans residing in this area, Jarvis told me in March 1961 that he gave up reading Science Fiction years ago, but he mentioned some of the old sf classics with great nostalgia.

Sincerely,
Ruth Berman

Laboratory Letter

Biocycling

"1st, have something to say; 2nd, say it; 3rd, stop when you've said it; 4th, give it an accurate title."—John Shaw Billings, M.D., 1828-1913, Prescription for Writing a Medical Paper.

Months ago in this journal* I wrote a paper "Parable of a Punctured Pathologist" saying the physiological variations of a prodigal pathologist's SMA-12/60 results far outstripped the analytical variation of the SMA-12/60 machine.

I laid it on the table:

TABLE 1

Quality Control Data on Daily Serum Samples of Pathologist After Various Physiological Events

	Physiological Variation	Analytical Variation	Ratio of Physiological to Analytical Variation
Calcium	0.15	0.1	1.5 times
Phosphorus	0.4	0.1	4.0 times
Glucose	18	2	9.0 times
BUN	3.0	0.4	7.5 times
Uric Acid	1.1	0.2	5.5 times
Cholesterol	16	6	2.7 times
T. Protein	0.2	0.1	2.0 times
Albumin	0.25	0.1	2.5 times
T. Bilirubin	0.6	0.04	15.0 times
Alk. P'tase	2.5	1.1	2.3 times
LDH	4.5	5.5	0.8 times
SGOT	6.0	2.7	2.2 times

Now some of you are saying the results are invalid because the pathologist didn't behave normally: too much food, too much drink, too much fasting. Just too much of the wrong things at the wrong time in the wrong amounts.

He was, in short, unfit for such an experiment.

Well-maybe he was and maybe he was not.

I discussed the matter with the fittest person I could find, a biochemist. He's fit because he bicycles eight and one-half miles to work and eight and one-half miles home again five days a week. On weekends, he really stretches out, sometimes pedalling 100 miles. He keeps fit, he says, partly because of diabetes, detected during childhood and requiring insulin. Anyway, he said he was going on a 211 mile bicycle marathon (107 miles on Saturday and 104 miles on Sunday). He would be at his fittest then and would be glad to confound the critics by repeating the experiment on himself. OK, I said, but no alcohol, no high protein meals, no non-fasting specimens, no hanky panky. All specimens to be drawn fasting at 8:30 A.M. after the eight and one-half mile ride to work. Everything had to be fit as a fiddle.

Here are the results for the skeptics of physiological variation.

TABLE 2

Analytical Variation of SMA-12/60 Results on Five Aliquots of One Serum Sample of Bicycling Biochemist

	Mean	Standard Deviation	Analytical Variation
Calcium	9.9	0.12	1.3%
Phosphorus	3.2	0.05	1.6%
Glucose	83.0	1.0	1.2%
BUN	17.2	0.4	2.3%
Uric Acid	3.1	0.17	5.5%
Cholesterol	266	10	3.7%
T. Protein	8.0	0.17	2.2%
Albumin	4.3	0.17	4.0%
T. Bilirubin	1.2	0.05	4.2%
Alk. P'tase	73	3.3	4.2%
LDH	172	8.8	4.5%
SGOT	56	2.8	5.0%

*December, 1971 issue, page 1035.

TABLE 3
Daily Changes of SMA-12/60 Chemistries of Bicycling Biochemist Before and After 211 Mile Bicycle Trip: Samples Drawn at 8:30 A.M. in Fasting State After 8½ Mile Ride to Work

	Pre-Trip	Immediately After 211 Mi. Bike Ride	One Day After	Two Days After	Three Days After	Four Days After	Five Days After	Eight Days After	Eleven Days After	Twenty Days After
Calcium	9.6	10.4	9.3	9.4	9.0	9.7	10.2	10.0	10.0	9.9
Phosphorus	3.4	5.2	3.3	2.9	2.9	3.3	3.7	4.5	4.1	3.2
Glucose	155	55	67	62	55	95	245	100	77	83
BUN	21	32	25	17	22	22	27	24	25	17
Uric Acid	2.8	4.8	2.7	2.8	2.4	2.1	1.9	3.2	3.4	3.1
Cholesterol	230	220	188	200	203	212	220	240	255	266

T. Protein	0.4	0.2	2.0 times
Albumin	0.2	0.1	2.0 times
T. Bilirubin	0.16	0.05	3.2 times
Alk. P'tase	16	3	5.3 times
LDH	19	9	2.1 times
SGOT	15 †	7	2.1 times†

*Not a true physiological variation since patient is a diabetic.
†Not a true physiological variation since strenuous exercise can cause skeletal muscles to leak transaminase; and because diabetic and post-exercise ketosis causes false-positive SGOT elevations.

There. I've said it.

Said what? (1) That physiological variation should be considered in interpreting borderline abnormal tests; and (2) That some people will go to ridiculous lengths to prove a point.

Richard L. Reece, M.D.
Minneapolis, Minnesota

Meeting

Pediatric Day will be held March 11, 1972 at the Mayo Clinic. The program will be comprised of a series of talks given by the faculty relating to pediatric problems. Dr. Mary Ellen Avery, Professor and Chairman of the Department of Pediatrics, McGill University, will be the guest speaker and will talk on oxygen and mist therapy. For information, write: Dr. E. C. Burke, Mayo Clinic, Rochester, Minnesota 55901.

That which is striking and beautiful is not always good, but that which is good is always beautiful.—Ninon de L'Enclos

Campbell's Soups... wide variety...for limited appetites

Many people lose interest in food as they grow older. Some of them are fussy eaters—with only a few favorite foods. Others become indifferent to foods—because planning and preparing meals becomes a chore. Here Campbell's Soups can help —for these four very good reasons:

Appeal With a variety of tastes, textures, aromas, and colors, Campbell's Soups can add interest and appetite appeal. And they're easy to eat—ingredients are tender, bite-size. Many patients on special diets will find soups they can enjoy among the more than 50 different varieties available.

Nourishment Campbell's Soups contain selected meats and sea foods, best garden vegetables—carefully processed to help retain their natural flavors and nutritive values.

Convenience Within 4 minutes a bowl of delicious soup is heated and ready to eat.

Economy Campbell's Soups are inexpensive—an important consideration to those whose budgets are limited.

Recommend Campbell's Soups . . . and, of course, enjoy them yourself. Remember, *there's a soup for almost every patient and diet . . . and for every meal.*

Break the ulcer circuit to hyperacidity, hypermotility and ulcer pain.

Pro-Banthine®
propantheline bromide
A Relief Factor in Peptic Ulcer

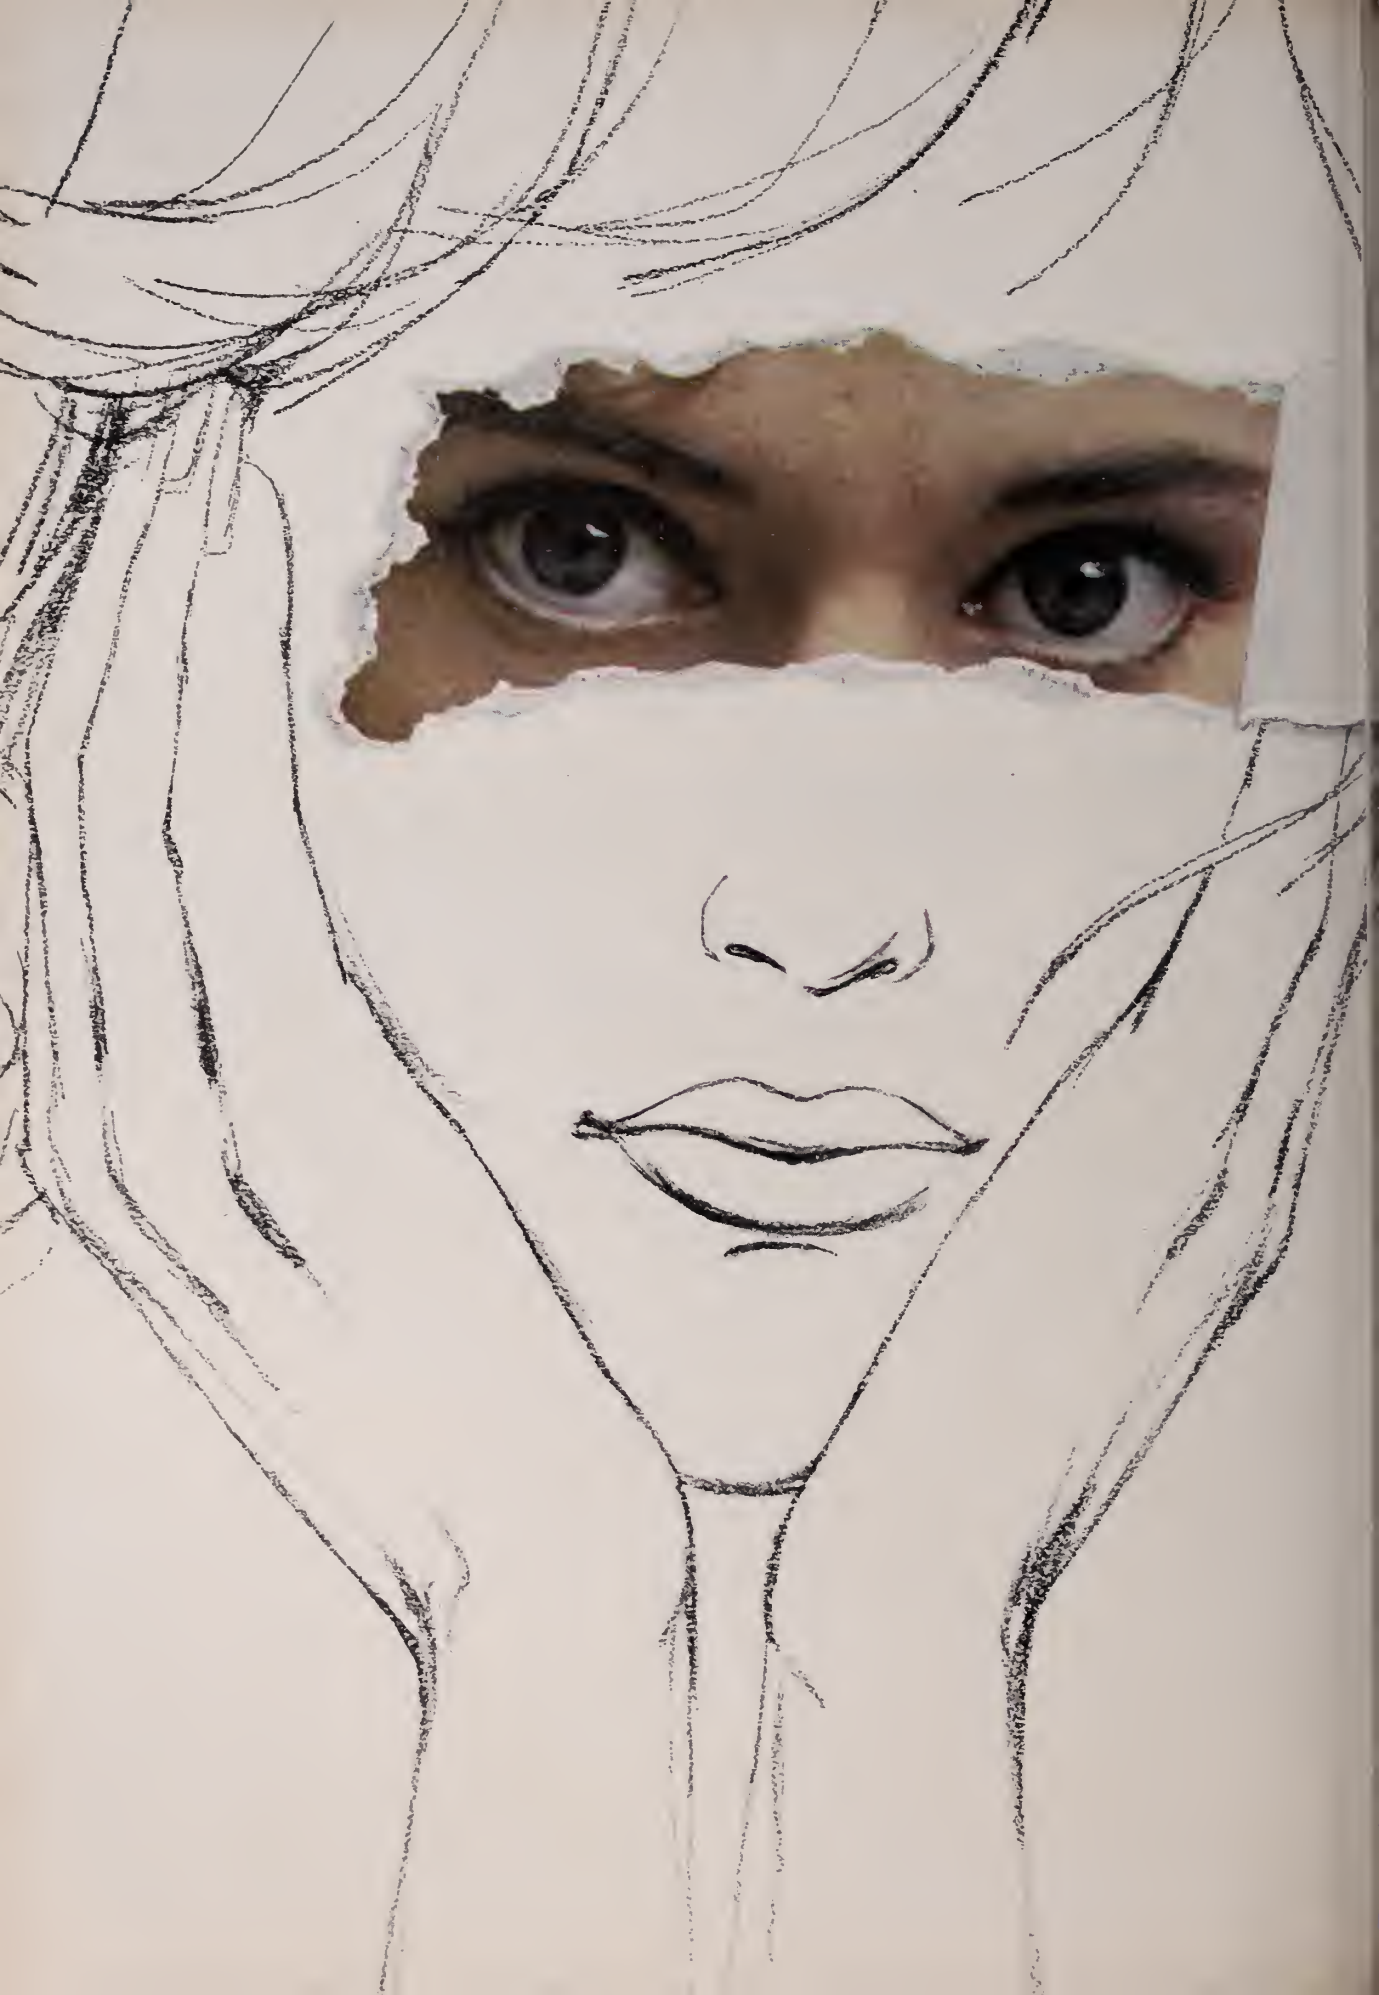
Worry, frustration, job pressure—all set up excessive vagal currents in patients with peptic ulcer.

Pro-Banthine "insulates" the stomach, the duodenum and the lower intestinal tract—the sites where these destructive currents take their toll.

This "insulation" helps block excessive enteric activity and acidity, thus helping to provide the proper environment for the healing of peptic ulcers.

It's nice to know that Pro-Banthine provides this protection at a dosage that causes little or no discomfort and that, unlike ataractic agents, Pro-Banthine does not cloud the patient's awareness or thought processes.

By moderating excessive vagal currents Pro-Banthine relieves spasm, acid burn and pain. By reducing gastric motility Pro-Banthine also prolongs the activity of antacids.



Indications: Peptic ulcer, gastroenteritis, pylorospasm, biliary dyskinesia, functional hypermotility and irritable colon.
Contraindications: Glaucoma, severe cardiac disease.
Precautions: Since varying degrees of urinary hesitancy may occur in elderly men with prostatic hypertrophy, this should be watched for in such patients until they have gained some experience with the drug. Although never reported, theoretically a curare-like action may occur with possible loss of voluntary muscle control. Such patients should receive prompt and continuing artificial respiration until the drug effect has been exhausted.

Side Effects: The more common side effects, in order of incidence, are xerostomia, mydriasis, hesitancy of urination and gastric fullness.

Dosage: The maximal tolerated dosage is usually the most effective. For most adult patients this will be four to six 15-mg. tablets daily in divided doses. In severe conditions as many as two tablets four to six times daily may be required. Pro-Banthine is supplied as tablets of 15 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg. The parenteral dose should be adjusted to the patient's requirement and may be up to 30 mg. or more every six hours, intramuscularly or intravenously.

SEARLE *Research in the Service of Medicine*
Distributed by G. D. Searle & Co., P. O. Box 5110, Chicago, Illinois 60680

Helps control the underlying problem– anxiety

Miltown®
(meprobamate)

when reassurance is not enough

Indications: Relief of anxiety and tension; adjunctively in various disease states in which anxiety and tension are manifested; and to promote sleep in anxious, tense patients.

Contraindications: Acute intermittent porphyria and allergic or idiosyncratic reactions to meprobamate or related compounds such as carisoprodol, mebutamate, tybamate, carbromal.

Warnings: *Drug Dependence:* Physical and psychological dependence and abuse have occurred. Chronic intoxication, from prolonged use and usually greater than recommended doses, leads to ataxia, slurred speech, vertigo. Carefully supervise dose and amounts prescribed, and avoid prolonged use, especially in alcoholics and addiction-prone persons. Sudden withdrawal after prolonged and excessive use may precipitate recurrence of pre-existing symptoms (e.g., anxiety, anorexia, insomnia) or withdrawal reactions (e.g., vomiting, ataxia, tremors, muscle twitching, confusional states, hallucinosis; rarely convulsive seizures, more likely in persons with CNS damage or pre-existent or latent convulsive disorders). Therefore, reduce dosage gradually (1-2 weeks) or substitute a short-acting barbiturate, than gradually withdraw. *Potentially Hazardous Tasks:* Driving a motor vehicle or operating machinery. *Additive Effects:* Possible additive effects between meprobamate, alcohol, and other CNS depressants or psychotropic drugs. *Pregnancy and Lactation:* Safe use not established; weigh potential benefits against potential hazards in pregnancy, nursing mothers, or women of childbearing potential. Animal data at five times the maximum recommended human dose show reduction in litter size due to resorption. Meprobamate appears in umbilical cord blood at or near maternal plasma levels, and in breast milk at levels 2-4 times that of maternal plasma. *Children Under Six:* Drug not recommended.

Precautions: To avoid oversedation, use lowest effective dose, particularly in elderly and/or debilitated patients. Consider possibility of suicide attempts; dispense least amount of drug feasible at any one time. To avoid excess accumulation, use caution in patients with compromised liver or kidney function. Meprobamate may precipitate seizures in epileptics.

Adverse Reactions: *Central Nervous System:* Drowsiness, ataxia, dizziness, slurred speech, headache, vertigo, weakness, paresthesias, impairment of visual accommodation, euphoria, overstimulation, paradoxical excitement, fast EEG activity. *Gastrointestinal:* Nausea, vomiting, diarrhea. *Cardiovascular:* Palpitations, tachycardia, various forms of arrhythmia, transient ECG changes, syncope; also, hypotensive crises (including one fatal case). *Allergic or Idiosyncratic:* Usually after 1-4 doses. Milder reactions: itchy, urticarial, or erythematous maculopapular rash (generalized or confined to groin). Others: leukopenia, acute nonthrombocytopenic purpura, petechiae, ecchymoses, eosinophilia, peripheral edema, adenopathy, fever, fixed drug eruption with cross reaction to carisoprodol, and cross sensitivity between meprobamate/mebutamate and meprobamate/carbromal. More severe, rare hypersensitivity: hyperpyrexia, chills, angioneurotic edema, bronchospasm, oliguria, anuria, anaphylaxis, erythema multiforme, exfoliative dermatitis, stomatitis, proctitis, Stevens-Johnson syndrome; bullous dermatitis (one fatal case after meprobamate plus prednisolone). Stop drug, treat symptomatically (e.g., possible use of epinephrine, antihistamines, and in severe cases corticosteroids). *Hematologic:* Agranulocytosis and aplastic anemia (rarely fatal), but no causal relationship established. Rarely, thrombocytopenic purpura. *Other:* Exacerbation of porphyric symptoms.

Usual Adult Dosage: 1200 to 1600 mg daily, in three or four divided doses; doses above 2400 mg daily not recommended.

Overdosage: Suicidal attempts with meprobamate, alone or with alcohol or other CNS depressants or psychotropic drugs, have produced drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse, and death. Empty stomach, treat symptomatically; cautiously give respiratory assistance, CNS stimulants, pressor agents as needed. Meprobamate is metabolized in the liver and excreted by the kidney. Diuresis and dialysis have been used successfully. Carefully monitor urinary output; avoid overhydration; observe for possible relapse due to incomplete gastric emptying and delayed absorption.

A Myopic Point of View

"Evans was extremely short-sighted, and a reluctant wearer of glasses. Without them, he could see small things held a few inches from his eyes in extraordinary detail, while everything else was a vague blur. Consequently the details he saw with microscopic exacitude, undistracted by the outside world, had a greater significance for him than for other men." (Evans, Joan. Time and Change: the story of Arthur Evans and his Forebears. London. 1943.)

SINCE THE EDITOR from time to time will comment on the medical scene, it might be well to establish the point of view from which these observations will be made. The point of view will be myopic for the reason that this is the natural state of the editor.

Myopia is a visual defect with many compensations. The fortunate victim carries with him a built-in magnifying glass that enables him to read the finest print with ease. All he needs do is whip off his glasses, and in my case I then have plus four diopter-stereo vision which roughly changes agate to pica type. In a theater darkened for the performance the less-gifted must strike a match to read the program. We myopes without spectacles simply bring the program closer, enlarge the image, and read.

Before the age of ten I knew that the only way to read the signs on the little clerestory-like window at the front end of a street-car was to run out into the street to get a closer view. An observant teacher put me in the front row, because I couldn't read the blackboard from the back of the room. When she found me leaving my front seat for a closer look, I was sent to the school nurse with the result, glasses.

Myopia to a degree is no handicap to a physician. He isn't required to see everything in perfect focus. For instance, a laboratory report may be that the fasting blood sugar is 120 mgm %. Anyone with good vision can read that the fasting blood sugar is 120 and, turning to his normal laboratory values, see that 60-100 is normal hence he is looking at an elevated fasting blood sugar. The myope can't see that well, hence he might question the elevation; can he trust his technician (or Technicon) for consistency of determination; has his laboratory been tested with unknowns against other laboratories; was his patient fasting when the nurses and laboratory technicians said he was? Or consider a change in a laboratory finding. A gastrointestinal bleeder comes in with a hemoglobin of 11.8 Gm/% and the following morning's reading is 11.5. Again the myope will have difficulty seeing the difference here, might ask the patient how he feels, observe the blood pressure, pulse, skin color, peer at the stool and ask for further hemoglobin readings only because knowing he has faulty vision, he needs more information than the sharper sighted.

I am recurrently amazed at the ability of my clear-sighted friends to see grade one Keith Wagner changes in the eye grounds after they find out what the high blood pressure reading is.

The myopic electrocardiographer is well advised to read his tracings with glasses, avoiding the magnification of unaided vision. He will be most helpful to the clinician if he focuses his blind spot on certain squiggles of the galvanometer: notches, detents, minute Q waves, microscopic S-T deviations. Again not having impeccable vision, he might read the chart or even (with the attending's consent) go over the patient. Finally, there is no better choice of investigator for a double-blind study than a myopic doctor.

The child who couldn't see "The Emporor's New Clothes"* obviously was severely myopic. One wonders what happened to him. With moderate negative lenses he might have grown up to make a fine physician.

Female Sterilization

THE ARTICLE in this issue by Thorsteinsson and Pratt* gives a review of the more frequently used sterilization procedures over the past 50 years.

The Madlener technique has an unacceptable failure rate and is no longer used. Methods such as described by Irving and Uchida trade an increase in operating time, blood loss and technical difficulty for a questionably lower failure rate as compared to the simple Pomeroy procedure.

The vaginal approach increases the failure rate in all the types of procedures and has a higher postoperative febrile morbidity. In addition, a certain number of cases will begin vaginally, but cannot be completed because adhesions prevent the fallopian tubes from being brought into the field.

The variation described in the article on the "Pratt Operation" appears significantly more time consuming, technically more difficult, and with a greater chance of blood loss since the tube is wedged out of the cornu of the uterus. No statistics on the number of times the procedure was done nor on the failure and complication rate are given in the article.

Currently I favor the following two approaches. In the immediate postpartum period, a very small incision is made at the inferior edge of the umbilicus and the tubes are ligated and divided by the Pomeroy technique using plain catgut. The total operating time is approximately twenty minutes and the reported failure rate is 0.3%.[1]

Virtually all our interval sterilizations are now being done by the laparoscopic technique recently described in this Journal.[2] Contrary to the statement in the article by Thorsteinsson and Pratt, a section of fallopian tube is removed by the laparoscopic biopsy forceps for definite histologic and legal evidence of interruption.

Subcutaneous Emphysema in Obstetrics*

INTRAPARTUM EMPHYSEMA is a rare disease, so unusual that an individual with an active practice in Obstetrics and Gynecology, will probably never diagnose such a patient unless he is unusually alert to the syndrome. The great variation in frequency observed from one in 200 deliveries to one in 100,000 is probably due to the minor degrees of emphysema reported in the former, and to severe disabling degrees in the latter. What is surprising, after reading the paper of Ebrahimi and Prem,* is not that intrapartum emphysema does occur, but that it does not occur in much greater numbers than we presently realize. The most likely explanation for intrapartum emphysema is "the violent strain of childbirth." This enormous intra-abdominal pressure is also manifested the next day or so following delivery in the rather prominent conjunctival hemorrhages we have all observed in some parturients. Yet hemorrhages in the eyegrounds are more commonly noted than subcutaneous emphysema. Other factors thus must be involved in intrapartum emphysema, possibly congenital weakness in one or more pulmonary alveoli. The disease is self limited, not lethal and the treatment consists of supportive measures. It must be differentiated from preeclampsia which can have a fatal outcome if not discovered.

Erratum

The February President's Letter stated 225 medical students would begin medical training in Minnesota in September, 1972. This should read: 225 students will begin medical training in Minneapolis, 40 in Rochester and 24 in Duluth.

Chemotherapy by Arterial Infusion

In Carcinoma of the Liver

EXTENSIVE METASTATIC DISEASE involving the liver responds poorly to systemic chemotherapy. Direct arterial infusion, however, is a valuable form of palliation. The techniques of intra-arterial infusion of localized malignant disease have been extensively studied recently and perfected. Techniques in use today vary from long-term continuous therapy with the Chronofusor to the relatively simple Fenwald pressure bag system. As reported in the paper by Doctors Fortuny, Theologides and Kennedy in this issue,* a variety of tumors may be treated with palliative benefit by these techniques. Many of their patients did not exhibit prolonged survival when compared to other members of the study group, but the quality of their survival was greatly enhanced in those persons who respond to the treatment.

As would be expected, those tumors which respond to intra-arterial infusion by means of the hepatic artery are those which have known response to the drug. Tumors which tend to be refractory to the drug being utilized normally would not be expected to respond and, indeed, most often do not even with the higher dosage achieved by means of direct arterial infusion. Carcinomas of the colon, pancreas and biliary tract are known to be responsive in some degree to systemic 5-fluorouracil and FUDR (deoxy-uridine) therapy. Likewise carcinoma of the breast is known to be a responder to fluorinated pyrimidine therapy. Hepatic metastatic disease from tumors primary in these organs can be expected to be responsive to intra-arterial infusion in a significant number of cases. The results are often dramatic in reduction in size of massively enlarged livers, disappearance of jaundice, and return of appetite and activity levels approaching, or reaching normal. With a good initial response to arterial infusion through the hepatic artery in metastatic carcinoma of the liver, one may attempt to maintain such responses by periodic systemic maintenance therapy with the same drug utilized for infusion. This is oftentimes effective for a long time and when breakthrough occurs, secondary infusion therapy can achieve remission. Should a case prove refractory to systemic maintenance therapy periodic reinfusion by means of the hepatic artery can be used to maintain the remission.

Although selective catheterization of the desired artery may be accomplished percutaneously, it is my experience that surgical placement of the catheter under direct vision is to be preferred over percutaneous placement. The anatomic variations known to exist within the arterial supply to the liver and biliary tree make it difficult to achieve isolated placement of the infusion catheter in the hepatic artery and dislodgment, as noted in the article mentioned, is common. The degree of systemic toxicity manifested during arterial infusion may well be related to the placement of the catheter since a dislodged catheter may present a fair amount of drug unaltered to the system without passage through the liver. If the patient is a satisfactory surgical candidate, the performance of a laparotomy to place the infusion catheter is justified and presents a permanent form of placement which allows reinfusion without a second manipulative procedure. The authors' point is well taken that appropriate equipment for placement of an infusion catheter should be present at the time of laparotomy for suspected carcinomas of the colon, biliary tract or pancreas. Obviously the risk of laparotomy is greater than that of percutaneous placement of the catheter but with careful technique the complication rate is low and the risk justified. In colon carcinoma where venous seeding of the liver is found at the time of primary operation and minimal disease is left following resection of the primary tumor, placement of an infusion catheter at the time of original laparotomy is advisable. Similarly in cases of pancreatic and biliary tract carcinoma the placement of the infusion catheter at the time of initial laparotomy is preferable when primary resection for cure is not possible. A second laparotomy for catheter placement or the manipulation of percutaneous catheter placement is thus avoided and the patient has a correctly placed catheter available for infusion therapy.

The modern surgeon must bear in mind not only primary treatment, but must also be aware of the methods of palliative management in the patient who is not resectable for cure. This again emphasizes the desirability of the team approach

See page 197.

n oncology with early communication between the arious disciplines involved when tumor manage- nent is considered.

The complications of arterial infusion therapy f the liver are minimal when careful observation nd laboratory controls are used. The toxic man- festations of fluorinated pyrimidines when used y direct arterial infusion are similar to those een with systemic therapy. Appropriate moni- oring by means of white blood count and platelet evels plus serum transaminase and lactic dehydro- enase levels will avoid undue problems. Stomati- is, diarrhea, and systemic toxic symptoms even- ually prescnt themselves in most cases if the nfusion is carried out for a long enough period. Close observation of serum enzymes and bilirubin evels must be maintained in the jaundiced patient n whom the infusate can be hepatotoxic. In such patient, the SGOT and LDH levels should prob- bly be monitored daily and any significant eleva- ion would indicate either the necessity to reduce he dosage of infusate or to discontinue the infusate or a period of time. Tolerance to infusion is greater with the catheter securely placed in the iepatic artery.

Patients being treated by percutaneously placed r surgically placed catheters may be treated as utpatients. The Fenwald system can be used for mbulatory infusion as well as the Chronofusor ystem. An active intelligent patient can be taught o change the infusion bag in the Fenwald system and with the smaller Fenwald bag, the patient may be restricted in little, if any, of his activities. Percutaneous catheterization through the arterial system of the upper extremity is more satisfactory for ambulatory infusion by the Fenwald system than by the femoral route.

Intra-arterial infusion of carcinoma involving the liver by means of hepatic artery cannulation is practical and effective. Palliation is achieved in a significant number of patients who would otherwise be unlikely responders to chemotherapeutic management. Fluorinated pyrimidines for such therapy are well established, undue toxicity is not encountered when the patient is carefully monitored by means of clinical and laboratory means. Although surgical placement of the infusion catheter is to be preferred as regards exact placement and lack of dislodgment, percutaneous catheterization is an accepted method. Catheter dislodgment occurs with percutaneous catheterization but replacement is simple in experienced hands. Ambulatory infusion is a practical method and can be accomplished with the Fenwald closed system or Chronofusor techniques. Palliation produced by this treatment is worthwhile and should be considered also when systemic chemotherapy is unsuccessful. Anticipation of such infusion should be a part of the surgeon's approach to suspected primary cases of carcinoma of the colon, biliary tree and pancreas and when indicated, the catheter placed at the time of the original laparotomy.

Case Report

Anterior Mediastinal Teratoids

An Unusual Case of Bilateral Mediastinal Tumors

S. K. IMES, M.D.* AND W. F. HOOK, M.D.*

IF WE EXCEPT LYMPHOMATA, which may be considered multicentric in origin, teratoids are the most common of all primary tumors of midanterior mediastinal origin.[3] Rusley[4] in an exhaustive review, analyzed all the mediastinal teratoid tumors in the world literature through 1939, adding six cases of his own, for a total of 245 cases. Numerous other reports have been published since.

Maier[2] reported unusual features in four patients with mediastinal teratoids. One patient presented with bilateral mediastinal tumors. Another rapidly developed tumor extension, inoperability, and widespread metastases after having been considered for several years as having an innocent dermoid because of peripheral calcification.

A search of the literature has failed to reveal other radiologic reports of multiple mediastinal teratoids; although small satellite lesions, not in direct communication with the main teratoid, have been reported in at least one instance in the surgical literature.[1] This report documents a second case of separate large bilateral midanterior mediastinal teratoid tumors discovered radiologically.

Case Report

A white male, age 58, was referred to the Radiology Department with complaints of upper abdominal distress associated with substernal pain and burning (heartburn), and moderate difficulty with urination. His blood pressure and physical findings were normal, with the exception of an enlarged prostate.

Radiographic Findings

Intravenous pyelography was normal with the exception of an enlarged prostate deforming the base of the urinary bladder and producing mild post voiding bladder retention. The cholecystographic study was normal. An upper gastrointestinal series revealed a moderately large sliding hiatus hernia with associated stress regurgitation of gastric contents into the esophagus.

Chest fluoroscopy and roentgenograms outlined what appeared to be three roughly spherical tumor masses in the midanterior mediastinum varying in size from four to seven centimeters in diameter. Peripheral calcification was present in all three masses. The smallest mass was seen nearly exactly in the midsagittal plane and approximately four centimeters deep to the sternum. The largest mass was situated more anteriorly, overlapped the midline, and protruded moderately into the right chest. The third mass lay slightly further posteriorly and projected into the left chect (Figures 1, 2, 3). Transmitted pulsatory movement was seen, particularly in the posterior left tumor. No fat fluid levels could be found and no bone or teeth were present. The chest study was otherwise radiologically normal. The radiologic diagnosis was dermoid tumor, either a multiple or a large single multilobated dermoid extending to both right and left sides of the mediastinum.

Laboratory studies demonstrated the hemoglobin to be 13.3 grams percent, the white blood count 5,700 with a normal differential, urinalysis normal, blood urea nitrogen 18.5 milligrams percent. The electrocardiogram was normal. Transurethral resection of the enlarged prostate had been done on December 13, 1966.

Fig. 1—Posterior anterior chest.

*Department of Radiology, Quain and Ramstad Clinic, Bismarck, North Dakota.

Fig. 2—Lateral chest.

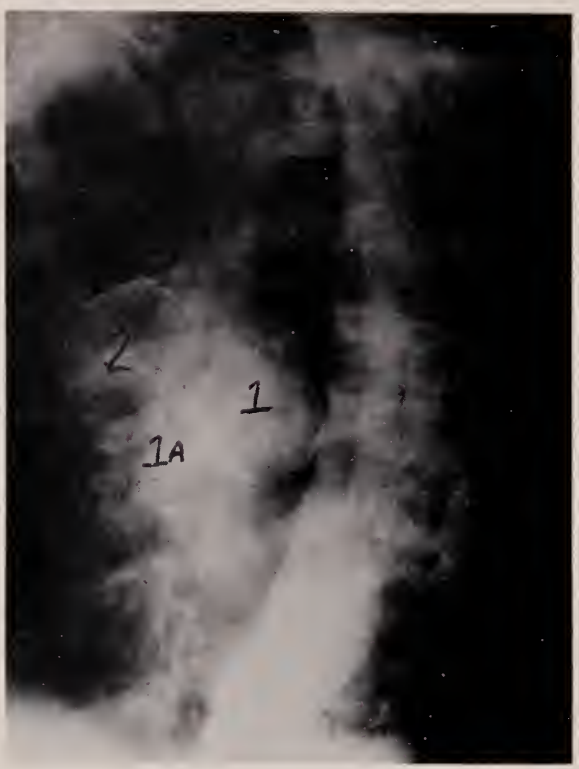

Fig. 3—Left anterior oblique chest.

Operative Findings

Mediastinal exploration was done on January 20, 1967, through a sternal splitting incision. Two separate mediastinal masses were encountered and removed by sharp and blunt dissection. Both masses were intimately adherent to the pleura, but mediastinal in origin. It was necessary to open the pleura to resect the masses. The bulk of the left mass projected posteriorly and bulged into the left chest, with a smaller lobe that projected into the midline area giving rise to the radiologic impression of a third smaller midline tumor. The pericardium was not involved. The bulk of the right tumor mass lay in the right mediastinum and bulged into the right chest. Microscopic pathologic diagnosis of both tumor masses was that of dermoid tumor without evidence of malignancy.

Summary

Teratoid tumor of the midanterior mediastinum is not rare, but apparently rarely present as more than a single lesion. Radiographs of only one such case were readily found in the literature. This report documents the radiologic discovery of a second case of bilateral separate midanterior mediastinal teratoid tumors. The left mediastinal tumor had a lobate extension in the midmediastinum, giving the radiographic appearance of a third tumor mass. Both tumors were surgically excised; microscopically both were diagnosed as benign dermoids.

Anesthesia*

Meigs, Professor of Midwifery at Jefferson Medical College (1841-1861), was markedly antagonistic to anesthesia in obstetrics, as noted by S. Weir Mitchell while a student at Jefferson in the late 1840's:

> "My father first in Philadelphia used ether in childbed. Professor Meigs violently opposed it and one day undertook to show its peril to a class of three hundred or more at Jefferson Medical School. A big billy goat was brought into the arena, which was called the bull ring, and Ellerolie Wallace, Dr. Meig's assistant, gave the ether. At last, Professor Meigs announced the demise of Billy, and the corpse was taken out and left in a small room at the halfway landing of the main stairway. The lecture over, we were noisily descending to the chemical lecture when Wallace opened the door to Billy's room. Out came Billy, very drunk, charged between Wallace's long legs into a mass of delighted students, and Billy and students went downstairs in one wild confusion. My father was never weary of inquiring of his colleague after this patient's health."

Despite this experience, Meigs retained his beliefs. Hodge, Professor of Midwifery at Pennsylvania (1835-1869), wrote in 1866:

> "Professor Meigs has strong protests against anaesthesia in labor, declaring that it is fraught with danger and predicting that, in the course of a few years, it will be banished from practice, except in a few extraordinary cases."

Medical Students

Six medical student at the University of Minnesota have received Student Achievement Awards worth $1,000 each for academic excellence, student leadership and community service.

The awards were sponsored jointly by the Minnesota Medical Foundation and the Hennepin County Medical Foundation.

The award winners are: Freddie L. Daniels, 1918 Elliot Ave. S.; Thomas E. Kottke, 501-21st Ave. S.; Robert P. Miller, 19 Barton Ave. S.E.; Charles L. Steinberg, Jr., 1720 Emerson Ave. So.; Michael Tripp, 3100 E. 22nd St., and Mark Wood, 3350 Edmund Blvd.

The awards recognize the students for individual achievements. Winners were nominated by classmates and faculty members and chosen by a committee made up of representatives of the two Foundations, the Medical School and private medical practice.

Empirin Compound with Codeine relieves aches, pains, fever and general malaise of colds and of **FLU**

A gratifying announcement about Empirin® Compound with Codeine

You may now specify up to five refills within six months when you prescribe Empirin Compound with Codeine (unless restricted by state law).

It is significant in this era of increased regulation, that Empirin Compound with Codeine has been placed in a less restrictive category. You may now wish to consider Empirin with Codeine even more frequently for its predictable analgesia in acute or protracted pain of moderate to severe intensity.

Empirin Compound with Codeine No. 3 contains codeine phosphate* (32.4 mg.) gr. ½. No. 4 contains codeine phosphate* (64.8 mg.) gr. 1. *(Warning—may be habit-forming.) Each tablet also contains: aspirin gr. 3½, phenacetin gr. 2½, caffeine gr. ½.

When you select this familiar antibiotic for IV infusion you have available a broad dosage rang that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

In usual IV doses, Lincocin (lincomyci hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water. But when 4 grams or more per day is given, Lincocin should be diluted in nc less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

ifections caused by susceptible strains
pneumococci, streptococci, and
aphylococci, including penicillin-
sistant strains. Staphylococcal strains
sistant to Lincocin (lincomycin
drochloride, Upjohn) have been
covered. Before initiating therapy,
lture and susceptibility studies should
performed. Lincocin has proved
luable in treating patients hyper-
nsitive to penicillin or cephalosporins,
ice Lincocin does not share
tigenicity with these compounds.
owever, hypersensitivity reactions
ve been reported, some of these in
tients known to be sensitive to
nicillin.

ell tolerated at infusion site: Lincocin
travenous infusions have not
oduced local irritation or phlebitis,
ien given as recommended. Lincocin
usually well tolerated in patients who
e hypersensitive to other drugs.
evertheless, Lincocin should be used
utiously in patients with asthma or
nificant allergies.

patients with impaired renal function,
e recommended dose of Lincocin
ould be reduced to 25–30% of
e dose for patients with normal
dney function. Its safety in
egnant patients and in infants
s than one month of age has
t been established.

ncocin may be used with other
timicrobial agents: Since Lincocin
stable over a wide pH range, it is
itable for incorporation in
ravenous infusions; it also may be
administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

972 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn)

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatme *Skin and mucous membranes*—Skin rash urticaria, vaginitis, and rare instances of e foliative and vesiculobullous dermatitis ha been reported. *Liver*—Although no direct r lationship to liver dysfunction is establishe jaundice and abnormal liver function te (particularly serum transaminase) have be observed in a few instances. *Cardiovascul* —Instances of hypotension following pare teral administration have been reporte particularly after too rapid IV administr tion. Rare instances of cardiopulmonary a rest have been reported after too rapid I administration. If 4.0 grams or more admi istered IV, dilute in 500 ml of fluid a administer no faster than 100 ml per hou *Special senses*—Tinnitus and vertigo ha been reported occasionally. *Local reactio* —Excellent local tolerance demonstrated intramuscularly administered Lincoc (lincomycin hydrochloride). Reports of pa following injection have been infrequen Intravenous administration of Lincocin 250 to 500 ml of 5% glucose in distille water or normal saline has produced n local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500 m* Capsules—bottles of 24 and 100. *Steri Solution, 300 mg per ml*—2 and 10 ml via and 2 ml syringe. *Syrup, 250 mg per 5 m* —60 ml and pint bottles.

For additional product information, consu the package insert or see your Upjoh representative.

Review

Acute Renal Failure

Indications for Dialysis

HENRY T. SMITH, M.D.*

ACUTE RENAL FAILURE is defined as the sudden development of impaired renal function from any of a number of medical and surgical conditions. It is usually accompanied by oliguria, i.e., output of less than 500cc per day, but azotemia may develop in the face of normal urine volume.[1] The standard renal failure regimen (fluid restriction, protein restriction, etc.) carries a distressing mortality rate (40-50%)—with infection being the most common cause of death. The use of peritoneal dialysis and hemodialysis has produced justifiable optimism for the management of these patients. However, these techniques do not supplant the more conservative measures; they merely supplement these measures. A common question is: "At what stage in the management of acute renal failure should one augment the conservative approach with dialysis?" It is the purpose of this paper to discuss some of the guidelines used in answering this question.

Indications

Indications for dialysis in acute renal failure are listed in Table 1. The development of the uremic syndrome (Table 2) in these patients is a clear indication for dialysis. Although the toxic substance or substances producing the syndrome have not yet been determined, the dramatic response to dialysis strongly suggests that many of the manifestations are due to a circulating dialyzable material.

Onset of Clinical Uremia

It is no longer considered satisfactory medical practice, however, to await or indeed to permit the development of uremia. In a review of this problem in 1963, Balslov and Jurgensen[2] noted that until 1960 the indications for dialysis were the onset of clinical uremia, or a serum urea level greater than 400 mgm per 100 ml, as well as symptomatic hyperkalemia and/or severe disturbances in other serum electrolytes. In 1960 Teschan[3] advanced the concept of "prophylactic dialysis" with the aim of dialyzing patients before the development of clinical uremia. His daily treatment of military patients produced such encouraging results that it initiated an almost universal trend toward early dialysis, so that severe clinical symptomatology and chemical abnormalities due to renal failure are rarely seen in many major centers. It was thought that early or prophylactic dialysis would reduce the morbidity and mortality associated with acute renal failure.

TABLE 1
Indications for dialysis in acute renal failure.

1. Uremic syndrome
2. BUN > 125-150mgm%
3. Rapidly rising BUN (> 30mgm% per day)
4. Marked fluid retention
5. Marked chemical distortion
6. Drug intoxication

TABLE 2
Uremic Syndrome

Gastrointestinal manifestations	Anorexia Nausea Vomiting Constipation or diarrhea Melena Mucosal ulcerations
Neuromuscular manifestations	Lethargy Apathy Mental Confusion Delusions Muscular twitching Peripheral neuropathy Convulsions
Cardiopulmonary manifestations	Pericarditis Overhydration Hypertension
Miscellaneous	Anemia Azotemia Acidosis Hyponatremia Hyperphosphatemia Hypocalcemia Hyperkalemia

*St. Louis Park Medical Center, Minneapolis, Minnesota.

These patients would thus be permitted to convalesce uneventfully from the precipitating disease or injury, with diet and activity restricted only by the underlying disease. With this regimen a significant improvement in wound healing was also noted: an observation substantiated experimentally in dogs. Nayman[4] reported that renal failure had no effect upon *healed* wounds in these animals, but uremia induced in the first five days of wound *healing* caused disruption in every case. After nine days wound healing was not affected. Early and regular hemodialysis prevented wound breakdown when renal failure was induced immediately after laparotomy.

It is impractical to consider daily dialysis in most clinical situations because of limited machinery and personnel. Therefore, some reasonable parameters—short of clinical uremia—are needed.

BUN (125-150mgm%)

Fischer et al.[5] in a retrospective study, noted a decrease in the mortality rate from 77% to 51% when dialysis was instituted to maintain the blood urea nitrogen below 150mgm%. Parsons et al.[6] found that the mortality rate fell from 88% to 25% if dialysis was used when the blood urea nitrogen reached 120-150mgm%. Scribner[7] has noted a similar improvement (69% to 26%) if early dialysis was utilized. It seems, therefore, that a blood urea nitrogen between 125mgm% and 150 mgm% represents a reasonable indication for dialysis, even if the patient's clinical condition is still satisfactory. This guideline, however, is not incontrovertible; many patients will recover uneventfully with conservative therapy after reaching this level. Neverthless, the bulk of the medical literature supports this suggestion as a reasonable approach. If there are signs of uremia prior to this level, then earlier dialysis may be necessary. This practice of earlier and more frequent dialysis has reduced mortality to 8-36% in those dialysis centers using vigorous preventive dialysis.[8]

The rate of rise of the blood urea nitrogen varies from patient to patient with conservative therapy. In a well managed patient this rate should not exceed 20mgm% per day. A rate in excess of 20-30mgm% per day provides warning of the need to prepare for dialysis or arrange transfer of the patient to a center that can provide dialysis.

Chemical Abnormalities

Other indications for dialysis in acute renal failure include fluid overload and various chemical abnormalities, such as metabolic acidosis. Because of the marked effectiveness of the cation exchange resins, hyperkalemia is generally not considered an indication for dialysis. It is always important to attempt to establish the etiology of the renal failure, because certain drugs and toxins require dialysis before the development of any of the aforementioned signs.[9]

Peritoneal Dialysis vs. Hemodialysis

The choice between peritoneal dialysis and hemodialysis depends primarily upon the availability of equipment, as well as the interests and experiences of the physicians managing the patient. Peritoneal dialysis can remove any metabolic product that can be removed by hemodialysis, although it requires about four times as long to achieve the same chemical improvement. There are no absolute contraindications to peritoneal dialysis, but there are a few relative contraindications, e.g., peritonitis or recent abdominal surgery. However, there are reports of peritoneal dialysis being instituted hours after repair of a perforated peptic ulcer, and within a week after appendectomy without harm. It has also been suggested that peritoneal irrigation might indeed be of value in the therapy of generalized peritonitis.[10]

Summary

The indications for dialysis have been broadened during the past decade in that an attempt has been made to prevent the development of the uremic syndrome and maintain the patient in an optimum condition while he recovers from his primary illness. Ideally there would be no restrictions regarding food and fluids, but expenses and limited equipment and personnel dictate the need for reasonable restrictions. Early and frequent dialysis is used to maintain the blood urea nitrogen less than 150mgm%. Dialysis is also necessary if conservative management results in a rate of rise in the blood urea nitrogen that is greater than 20mgm% per day. The improvement in morbidity and mortality attest to the wisdom of this approach.

Dr. John Merrill[11] has summarized the overall approach to dialysis in acute renal failure:

"The prime indication for treatment with the artificial kidney continues to be that first suggested by Abel, i.e., to maintain life and reasonable well-being during periods of acute renal insufficiency where the underlying lesion is reversible. The development of our understanding of the general therapeutic problems of acute renal failure has progressed to the point where the artificial kidney, in many cases, is unnecessary for the treatment of this syndrome. Under no circumstances should one entertain the concept that the artificial kidney is a substitute for good conservative management."

Cardiopulmonary Schistosomiasis Syndrome

This syndrome consists of cardiac or pulmonary symptoms caused by bilharzic infestation of the lungs secondary to *Schistosoma mansoni* in the intestinal tract or *S. haematobium* in the urinary tract. The presence of *Schistosoma* in the lungs was recognized as early as 1885. Sorour in 1928 described the pathologic lesions these parasites produce in pulmonary tissues. In the Near East the condition is common and is a recognized cause of right-sided heart failure. Males are more frequently affected than females. Age incidence is usually between 12 and 35 years.

The local pathologic lesions are those of obliterative pulmonary arteriolitis, produced by lodging of the ova in the arteriolar wall. A sufficient number of such lesions causes dilatation of the main pulmonary artery and hypertrophy of the right ventricle. Roentgenograms show fine, diffuse mottling as well as mitral configuration of the heart. An outstanding difference between Ayerza's syndrome, which is characterized by intense cyanosis, and cardiopulmonary schistosomiasis is that in the latter condition cyanosis occurs only terminally. Other diseases that may stimulate bilharzic cor pulmonale are rheumatic mitral insufficiency, patient ductus arteriosus, and patent interauricular septum. Antimony is a specific therapeutic agent in *Schistosoma* infestation; however, as this drug may exert a toxic effect upon the myocardium, its intensive use in this combined cardiopulmonary syndrome is contraindicated.

Pre-Sate®
(chlorphentermine HCl)

CAUTION: Federal law prohibits dispensing without prescription.

Indications: Pre-Sate (chlorphentermine hydrochloride) is indicated in exogenous obesity, as a short term (*i.e.*, several weeks) adjunct in a regimen of weight reduction based upon caloric restriction.

Contraindications: Glaucoma, hyperthyroidism, pheochromocytoma, hypersensitivity to sympathomimetic amines, and agitated states. Pre-Sate (chlorphentermine hydrochloride) is also contraindicated in patients with a history of drug abuse or symptomatic cardiovascular disease of the following types: advanced arteriosclerosis, severe coronary artery disease, moderate to severe hypertension, or cardiac conduction abnormalities with danger of arrhythmias. The drug is also contraindicated during or within 14 days following administration of monamine oxidase inhibitors, since hypertensive crises may result.

Warnings: When weight loss is unsatisfactory the recommended dosage should not be increased in an attempt to obtain increased anorexigenic effect; discontinue the drug. Tolerance to the anorectic effect may develop. Drowsiness or stimulation may occur and may impair ability to engage in potentially hazardous activities such as operating machinery, driving a motor vehicle, or performing tasks requiring precision work or critical judgment. Therefore, such patients should be cautioned accordingly. Caution must be exercised if Pre-Sate (chlorphentermine hydrochloride) is used concomitantly with other central nervous system stimulants. There have been reports of pulmonary hypertension in patients who received related drugs.

Drug Dependence: Drugs of this type have a potential for abuse. Patients have been known to increase the intake of drugs of this type to many times the dosages recommended. In long-term controlled studies with high dosages of Pre-Sate, abrupt cessation did not result in symptoms of withdrawal.

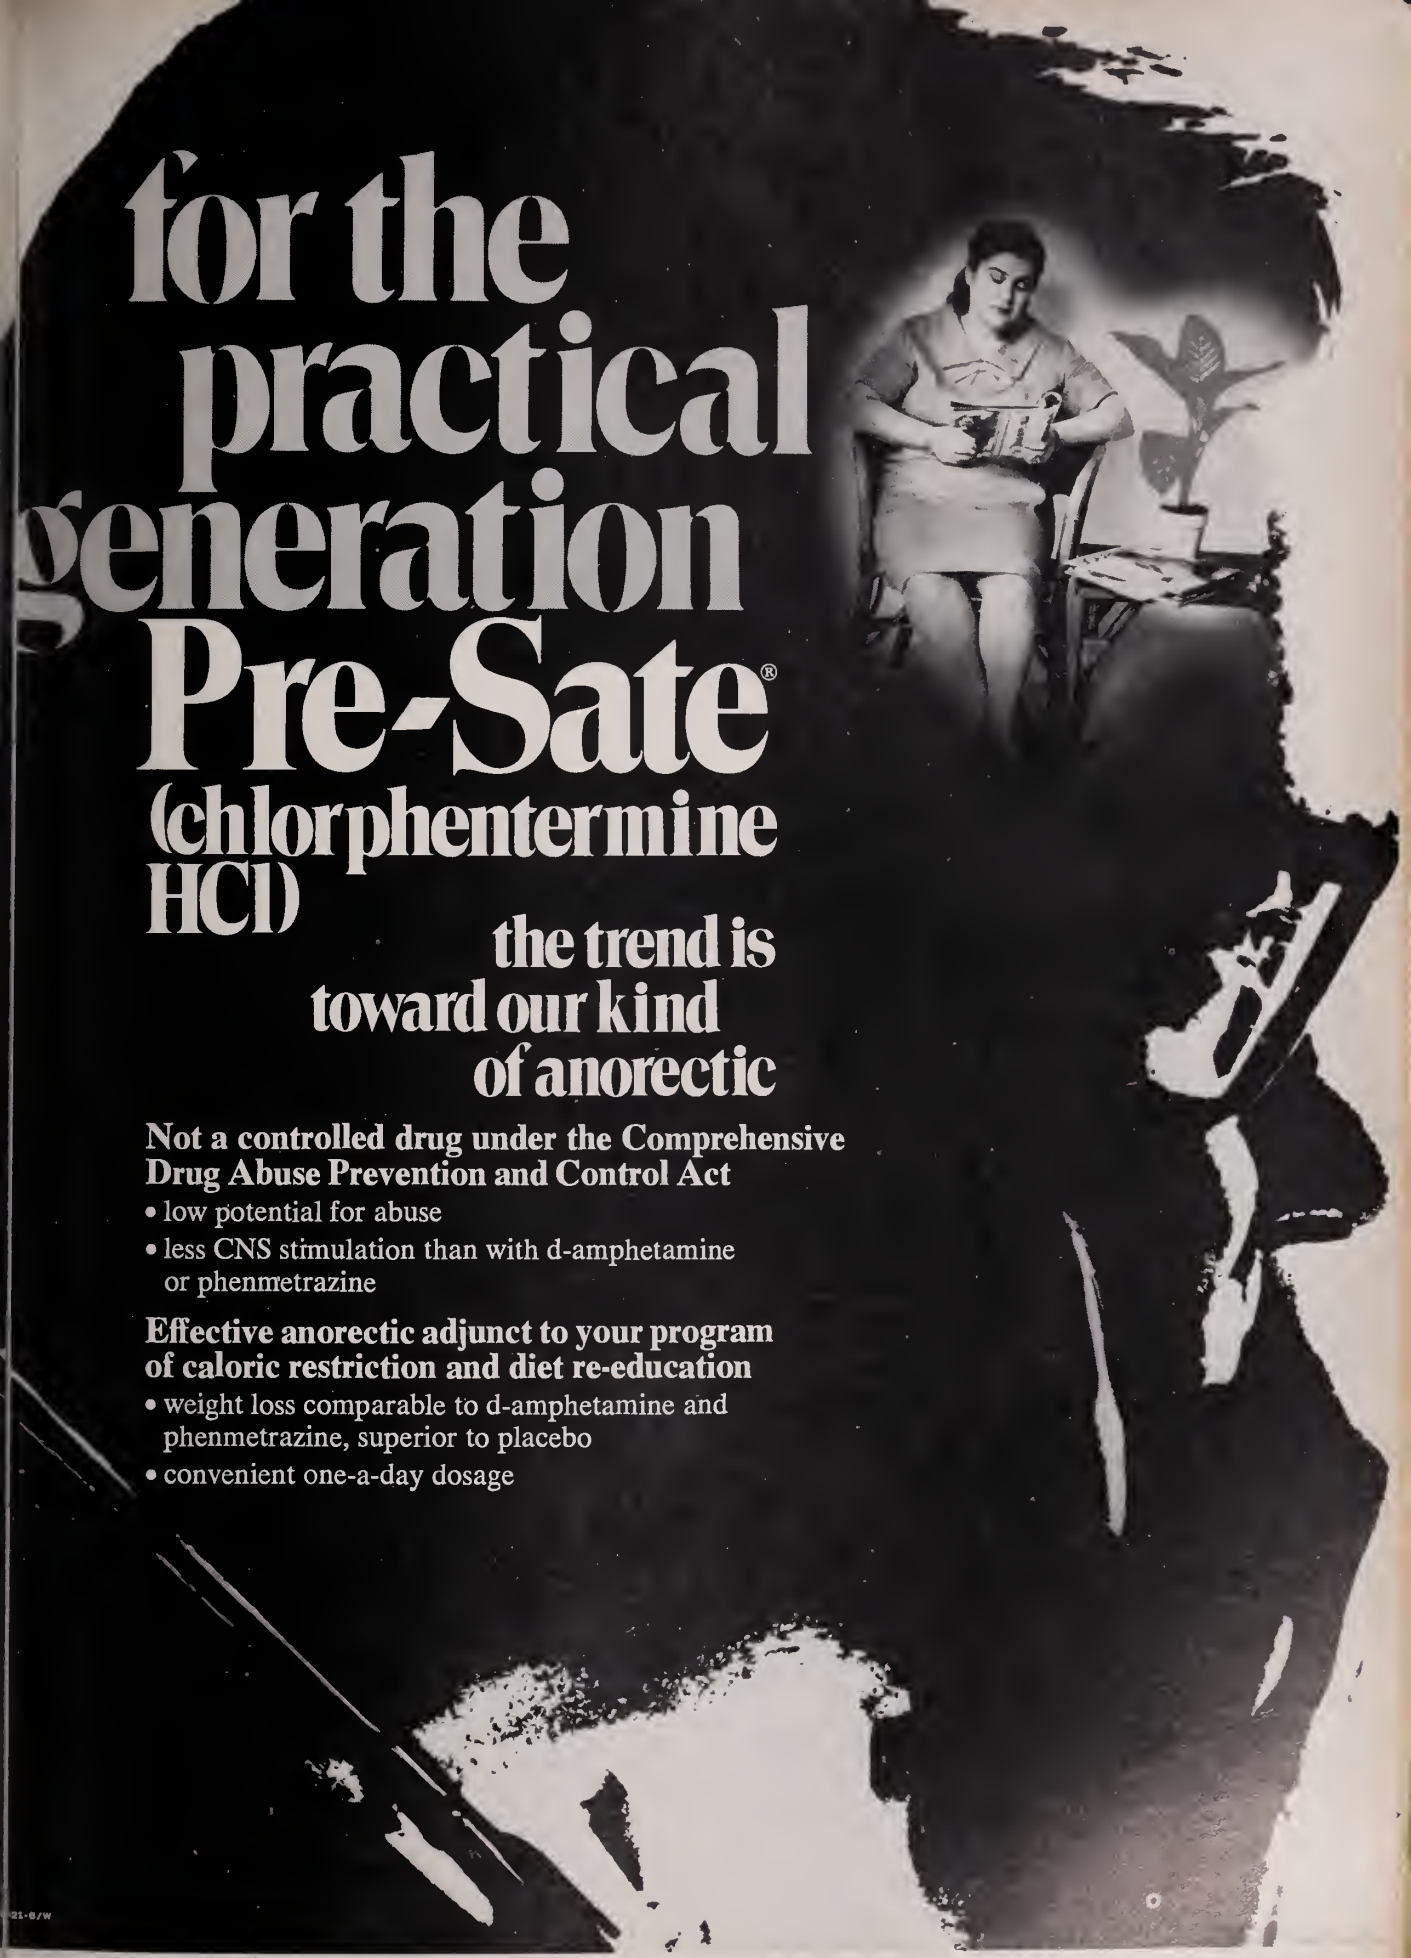
Usage In Pregnancy: The safety of Pre-Sate (chlorphentermine hydrochloride) in human pregnancy has not yet been clearly established. The use of anorectic agents by women who are or who may become pregnant, and especially those in the first trimester of pregnancy, requires that the potential benefit be weighed against the possible hazard to mother and child. Use of the drug during lactation is not recommended. Mammalian reproductive and teratogenic studies with high multiples of the human dose have been negative.

Usage In Children: Not recommended for use in children under 12 years of age.

Precautions: In patients with diabetes mellitus there may be alteration of insulin requirements due to dietary restrictions and weight loss. Pre-Sate (chlorphentermine hydrochloride) should be used with caution when obesity complicates the management of patients with mild to moderate cardiovascular disease or diabetes mellitus, and only when dietary restriction alone has been unsuccessful in achieving desired weight reduction. In prescribing this drug for obese patients in whom it is undesirable to introduce CNS stimulation or pressor effect, the physician should be alert to the individual who may be overly sensitive to this drug. Psychologic disturbances have been reported in patients who concomitantly receive an anorexic agent and a restrictive dietary regimen.

Adverse Reactions: Central Nervous System: When CNS side effects occur, they are most often manifested as drowsiness or sedation or overstimulation and restlessness. Insomnia, dizziness, headache, euphoria, dysphoria, and tremor may also occur. Psychotic episodes, although rare, have been noted even at recommended doses. **Cardiovascular:** tachycardia, palpitation, elevation of blood pressure. **Gastrointestinal:** nausea and vomiting, diarrhea, unpleasant taste, constipation. **Endocrine:** changes in libido, impotence. **Autonomic:** dryness of mouth, sweating, mydriasis. **Allergic:** urticaria. **Genitourinary:** diuresis and, rarely, difficulty in initiating micturition. **Others:** Paresthesias, sural spasms.

Dosage and Administration: The recommended adult daily dose of Pre-Sate (chlorphentermine hydrochloride) is one tablet (equivalent to 65 mg chlorphentermine base) taken after the first meal of the day. Use in children under 12 not recommended.



Overdosage: Manifestations: Restlessness, confusion, assaultiveness, hallucinations, panic states, and hyperpyrexia may be manifestations of acute intoxication with anorectic agents. Fatigue and depression usually follow the central stimulation. Cardiovascular effects include arrhythmias, hypertension, or hypotension and circulatory collapse. Gastrointestinal symptoms include nausea, vomiting, diarrhea, and abdominal cramps. Fatal poisoning usually terminates in convulsions and coma.

Management: Management of acute intoxication with sympathomimetic amines is largely symptomatic and supportive and often includes sedation with a barbiturate. If hypertension is marked, the use of a nitrate or rapidly acting alpha-receptor blocking agent should be considered. Experience with hemodialysis or peritoneal dialysis is inadequate to permit recommendations in this regard.

How Supplied: Each Pre-Sate (chlorphentermine hydrochloride) tablet contains the equivalent of 65 mg chlorphentermine base; bottles of 100 and 1000 tablets.

Full information available on request.

Pre-Sate® (chlorphentermine HCl)...the increasingly practical appetite suppressant

What makes 'Deprol' useful for depressed geriatric patients.. makes it useful for younger patients as well

- helps ease mild to moderate nonpsychotic depression *and* related anxiety
- helps assure a good night's rest

The middle-aged housewife who can't stop feeling "blue," who worries about losing her attractiveness yet neglects her appearance; reports vague aches and pains, difficulty sleeping, loss of appetite.

INDICATIONS: Useful in the management of depression, both acute (reactive) and chronic; particularly useful in the less severe depressions and where the depression is accompanied by anxiety, insomnia, agitation, or rumination; also useful for management of depression and associated anxiety accompanying or related to organic illnesses.
CONTRAINDICATIONS: Benactyzine hydrochloride: Glaucoma and previous allergic or idiosyncratic reactions to benactyzine hydrochloride or related compounds. **Meprobamate:** Acute intermittent porphyria and allergic or idiosyncratic reactions to meprobamate or related compounds such as carisoprodol, mebutamate, tybamate, carbromal.
WARNINGS: The following information on meprobamate pertains to 'Deprol' (meprobamate + benactyzine hydrochloride): **Meprobamate:** *Drug Dependence:* Physical and psychological dependence and abuse have occurred. Chronic intoxication, from prolonged use and usually greater than recommended doses, leads to ataxia, slurred speech, vertigo. Carefully supervise dose and amounts prescribed, and avoid prolonged use, especially in alcoholics and addiction-prone persons. Sudden withdrawal after prolonged and excessive use may precipitate recurrence of pre-existing symptoms (e.g., anxiety, anorexia, insomnia) or withdrawal reactions (e.g., vomiting, ataxia, tremors, muscle twitching, confusional states, hallucinosis; rarely convulsive seizures, more likely in persons with CNS damage or pre-existent or latent convulsive disorders). Therefore, reduce dosage gradually (1-2 weeks) or substitute a short-acting barbiturate, then gradually withdraw. *Potentially Hazardous Tasks:* D... a motor vehicle or operating machinery. *Additive Effects:* Possibl... tive effects between meprobamate, alcohol, and other CNS depre... or psychotropic drugs. *Pregnancy and Lactation:* Safe use not estab... weigh potential benefits against potential hazards in pregnancy, n... mothers, or women of childbearing potential. Animal data at five ... the maximum recommended human dose show reduction in litte... due to resorption. Meprobamate appears in umbilical cord blood ... near maternal plasma levels, and in breast milk at levels 2-4 time ... of maternal plasma. *Children Under Six:* Drug not recommended.
PRECAUTIONS: Meprobamate: To avoid oversedation, use lowest ... tive dose, particularly in elderly and/or debilitated patients. Conside... sibility of suicide attempts; dispense least amount of drug feasible ... one time. To avoid excess accumulation, use caution in patients wit... promised liver or kidney function. Meprobamate may precipitate se... in epileptics.
ADVERSE REACTIONS: Nausea, dry mouth, other g.i. symptoms ... cope; one case each of severe nervousness and loss of power of co... tration. The following side effects, which have occurred after administr... of its components alone, have either occurred or might occur whe... combination is taken. **Benactyzine hydrochloride:** Benactyzine h... chloride alone, particularly in high dosage, may produce dizziness, th... blocking, a sense of depersonalization, aggravation of anxiety, or ...

When mild depression and associated anxiety interfere with living

DEPROL®

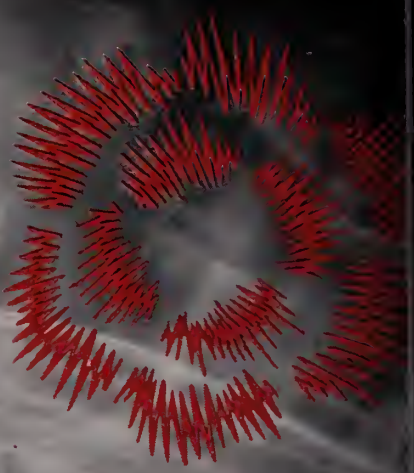
(meprobamate 400 mg + benactyzine hydrochloride 1 mg)

The junior executive crushed by his repeated failure to be promoted and anxious about the future; complains to you of listlessness, early-morning awakening.

The young widow whose grief has persisted too long, is pessimistic and fearful about what lies ahead, has lost interest in everything; is preoccupied with vague physical ailments, has crying spells.

ace of sleep patterns, and a subjective feeling of muscle relaxation. ere may also be anticholinergic effects such as blurred vision, dryness mouth, or failure of visual accommodation. Other reported side effects e included gastric distress, allergic response, ataxia, and euphoria. **probamate:** *Central Nervous System:* Drowsiness, ataxia, dizziness, rred speech, headache, vertigo, weakness, paresthesias, impairment of ual accommodation, euphoria, overstimulation, paradoxical excite- nt, fast EEG activity. *Gastrointestinal:* Nausea, vomiting, diarrhea. *Car- vascular:* Palpitations, tachycardia, various forms of arrhythmia, tran- nt ECG changes, syncope; also, hypotensive crises (including one fatal se). *Allergic or Idiosyncratic:* Usually after 1-4 doses. Milder reactions: ny, urticarial, or erythematous maculopapular rash (generalized or nfined to groin). Others: leukopenia, acute nonthrombocytopenic pur- ra, petechiae, ecchymoses, eosinophilia, peripheral edema, adenopa- , fever, fixed drug eruption with cross reaction to carisoprodol, and ss sensitivity between meprobamate/mebutamate and meprobamate/ bromal. More severe, rare hypersensitivity: hyperpyrexia, chills, angio- urotic edema, bronchospasm, oliguria, anuria, anaphylaxis, erythema ltiforme, exfoliative dermatitis, stomatitis, proctitis, Stevens-Johnson ndrome; bullous dermatitis (one fatal case after meprobamate plus ednisolone). Stop drug, treat symptomatically (e.g., possible use of nephrine, antihistamines, and in severe cases corticosteroids). *Hema- ogic:* Agranulocytosis and aplastic anemia (rarely fatal), but no causal relationship established. Rarely, thrombocytopenic purpura. *Other:* Exacerbation of porphyric symptoms.

USUAL ADULT DOSAGE: One tablet three or four times daily, which may be increased gradually to six tablets daily and gradually reduced to maintenance levels upon establishment of relief. Doses above six tablets daily are not recommended.



OVERDOSAGE: Overdosage of 'Deprol' (meprobamate + benactyzine hydrochloride) has not differed substantially from meprobamate overdosage: **Meprobamate:** Suicidal attempts with meprobamate, alone or with alcohol or other CNS depressants or psychotropic drugs, have produced drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse, and death. Empty stomach, treat symptomatically, cautiously give respiratory assistance, CNS stimulants, pressor agent, as needed. Meprobamate is metabolized in the liver and excreted by the kidney. Diuresis and dialysis have been used successfully. Careful monitor urinary output; avoid overhydration; observe for possible re[illegible] to incomplete gastric emptying and delayed absorption.

Before prescribing, consult package circular or latest PDR information.

WALLACE PHARMACEUTICALS, Cranbury, N.J. 08512

Rapid onset of action for the up-tight back in pain

(including intervertebral disc)

Indications: For symptomatic relief in conditions characterized by skeletal muscle spasm and mild to moderate pain.

Contraindications: Acute intermittent porphyria and allergic or idiosyncratic reactions to carisoprodol or related compounds such as meprobamate, mebutamate, tybamate.

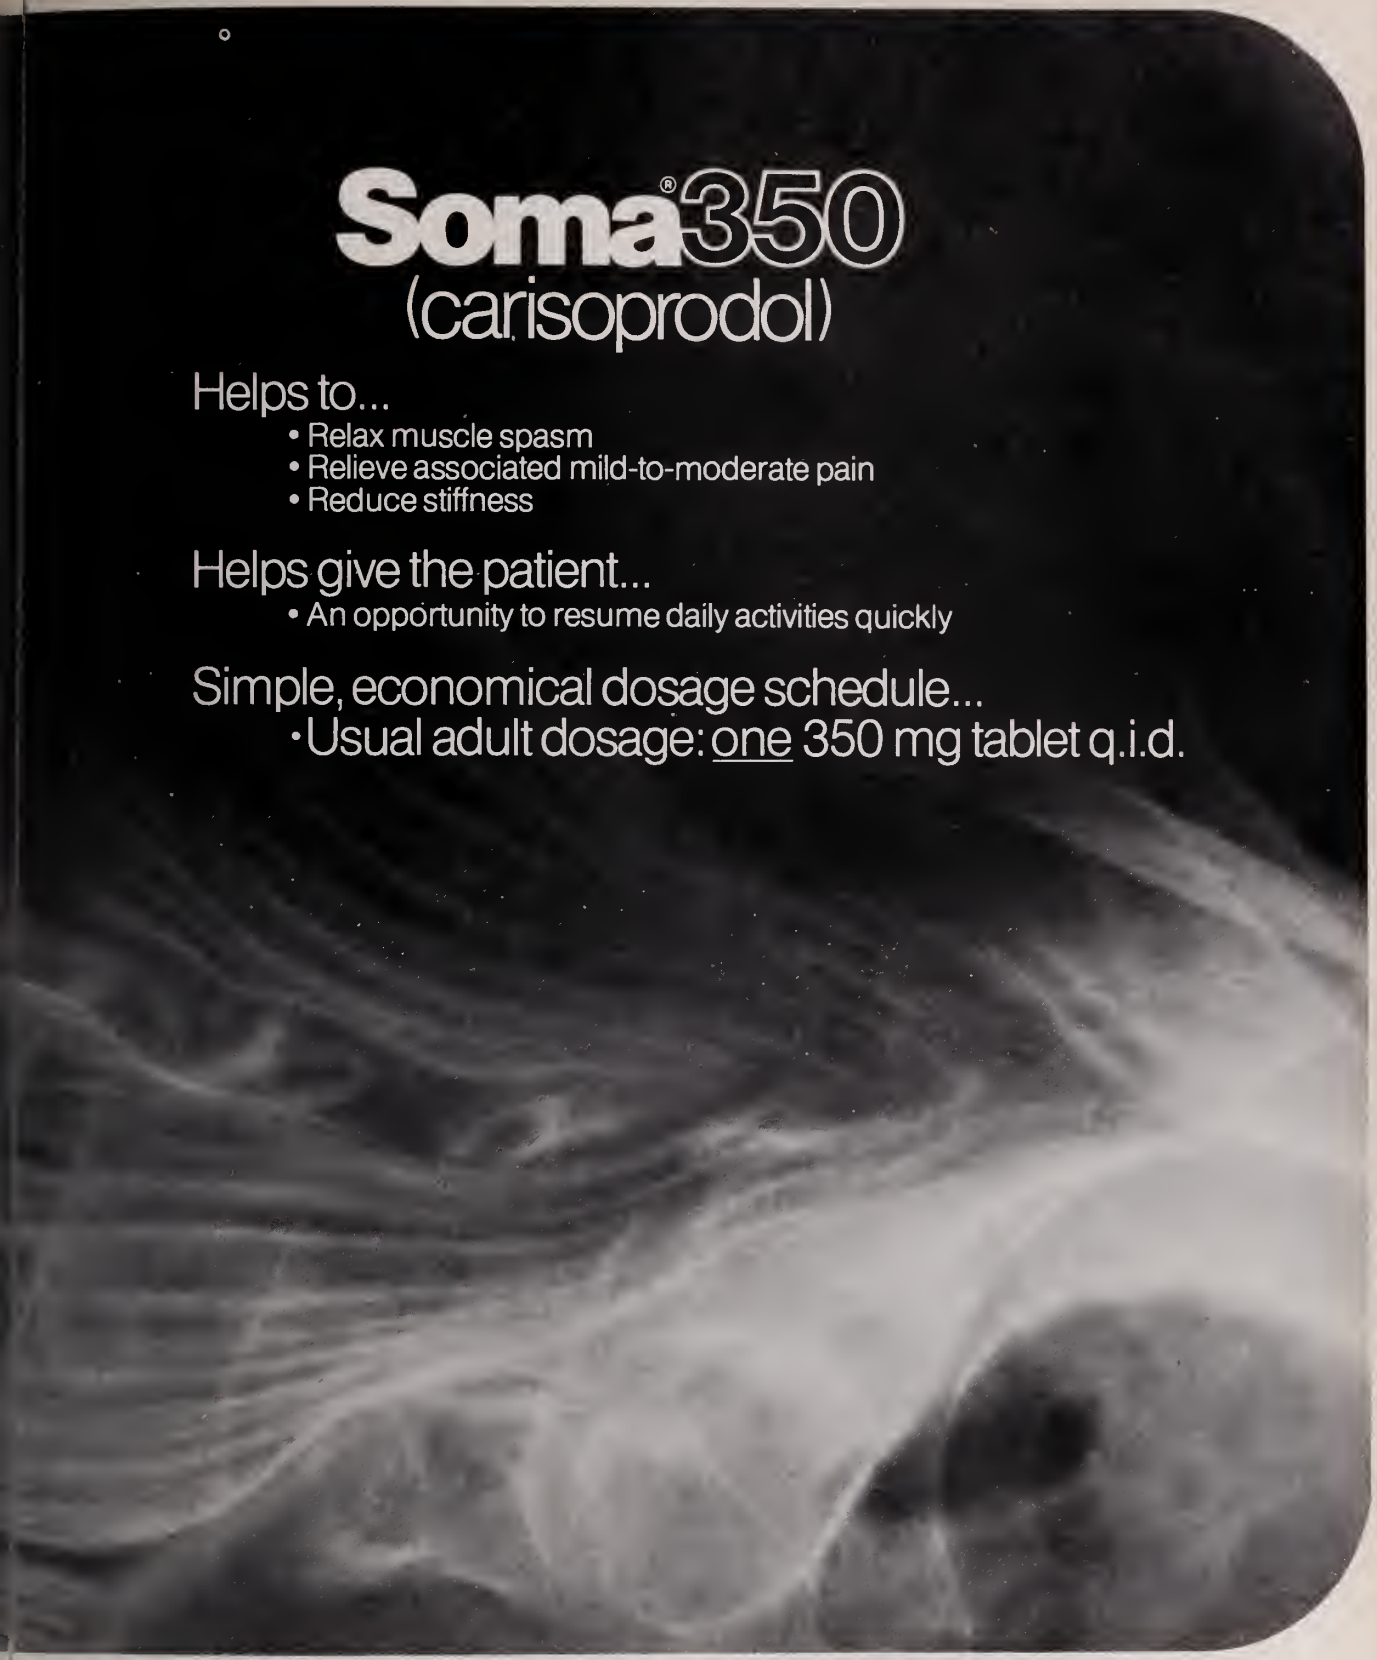
Warnings: *Idiosyncratic Reactions:* Rarely, first dose has been followed by extreme weakness, transient quadriplegia, dizziness, ataxia, temporary vision loss, diplopia, mydriasis, dysarthria, agitation, euphoria, confusion, disorientation. Symptoms usually subside during the next several hours. Supportive and symptomatic therapy, including hospitalization, may be necessary. *Pregnancy and Lactation:* Safe use not established; weigh potential benefits against potential hazards in pregnancy, nursing mothers, or women of childbearing potential. *Children Under Five:* Drug not recommended. *Potentially Hazardous Tasks:* Driving a motor vehicle or operating machinery. *Additive Effects:* Possible additive effects between carisoprodol, alcohol, and other CNS depressants or psychotropic drugs. *Drug Dependence:* Use cautiously in addiction-prone patients.

Precautions: To avoid excess accumulation, use caution in patients with compromised liver or kidney function.

Adverse Reactions: *Central Nervous System:* Drowsiness, dizziness, vertigo, ataxia, tremor, agitation, irritability, headache, depressive reactions, syncope, insomnia. *Allergic or Idiosyncratic:* Usually seen after 1-4 doses in patients not previously exposed, e.g., rash, erythema multiforme, pruritus, eosinophilia, fixed drug

Soma® 350
(carisoprodol)

Helps to...



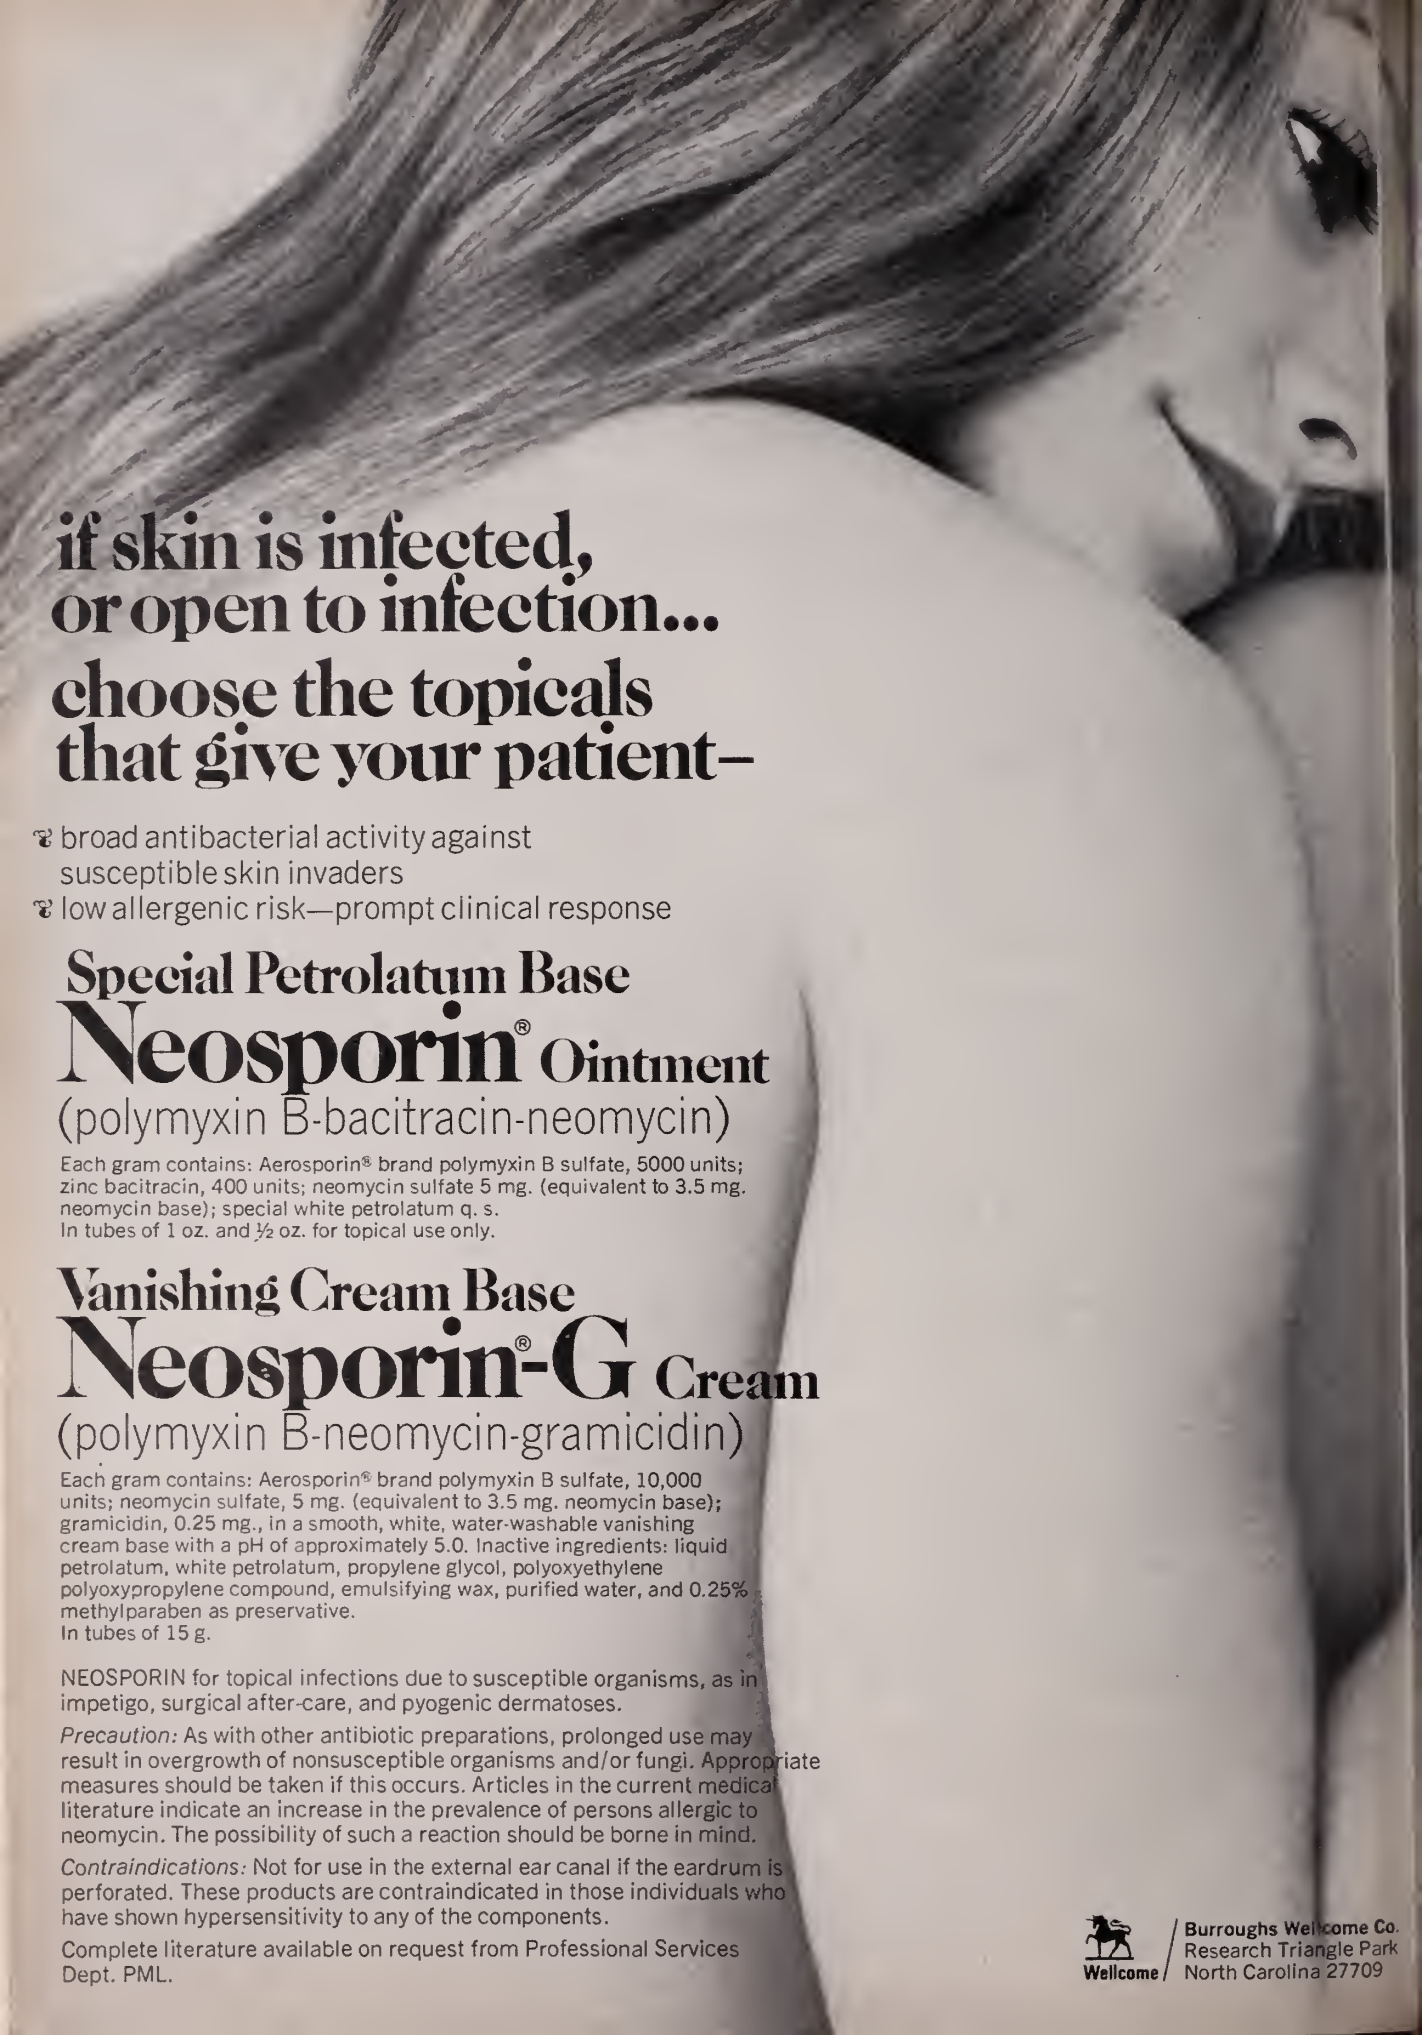
- Relax muscle spasm
- Relieve associated mild-to-moderate pain
- Reduce stiffness

Helps give the patient...

- An opportunity to resume daily activities quickly

Simple, economical dosage schedule...

- Usual adult dosage: one 350 mg tablet q.i.d.



eruption with cross reaction to meprobamate. More severe manifestations: asthma, fever, weakness, dizziness, angioneurotic edema, smarting eyes, hypotension, anaphylactoid shock. Stop drug, treat symptomatically (e.g., possible use of epinephrine, antihistamines, and in severe cases corticosteroids). *Cardiovascular:* Tachycardia, postural hypotension, facial flushing. *Gastrointestinal:* Nausea, vomiting, hiccup, epigastric distress. *Hematologic:* Leukopenia and pancytopenia (on carisoprodol plus other drugs).

Usual Adult Dosage: One 350 mg tablet three times daily and at bedtime.

Overdosage: Has produced stupor, coma, shock, respiratory depression, and, very rarely, death. Overdosage of carisoprodol plus alcohol or other CNS depressants or psychotropic drugs can be additive. Empty stomach, treat symptomatically; cautiously give respiratory assistance, CNS stimulants, pressor agents as needed. Carisoprodol is metabolized in the liver and excreted by the kidney. Diuresis and dialysis have been used successfully with related drug meprobamate. Carefully monitor urinary output; avoid overhydration; observe for possible relapse due to incomplete gastric emptying and delayed absorption. REV. 10/71

WALLACE PHARMACEUTICALS / Cranbury, N.J. 08512

if skin is infected, or open to infection... choose the topicals that give your patient–

- broad antibacterial activity against susceptible skin invaders
- low allergenic risk—prompt clinical response

Special Petrolatum Base
Neosporin® Ointment
(polymyxin B-bacitracin-neomycin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 5000 units; zinc bacitracin, 400 units; neomycin sulfate 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q. s.
In tubes of 1 oz. and ½ oz. for topical use only.

Vanishing Cream Base
Neosporin®-G Cream
(polymyxin B-neomycin-gramicidin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 10,000 units; neomycin sulfate, 5 mg. (equivalent to 3.5 mg. neomycin base); gramicidin, 0.25 mg., in a smooth, white, water-washable vanishing cream base with a pH of approximately 5.0. Inactive ingredients: liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax, purified water, and 0.25% methylparaben as preservative.
In tubes of 15 g.

NEOSPORIN for topical infections due to susceptible organisms, as in impetigo, surgical after-care, and pyogenic dermatoses.

Precaution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: Not for use in the external ear canal if the eardrum is perforated. These products are contraindicated in those individuals who have shown hypersensitivity to any of the components.

The Thalamic Pain Syndrome

THOMAS R. SMITH, M.D.*

THE THALAMIC PAIN syndrome was first described in 1906 by Dejerine and Roussy[4] whose description is still felt to be the most reliable. The most prominent features of this disorder include:

Clinical Manifestations

Continuous pain on the side contralateral to the thalamic lesion, usually described as varying from an ache, to a boring, gnawing, burning, icy or crushing sensation.[11] The trunk is often the site of such pain, but the limbs are not spared.[6] The pain may be increased by sensory stimuli such as intense light, loud noises, penetrating odors, cold water hitting the skin, seeing water or taking a drink. Widespread and diverse vasomotor and other autonomic disorders are associated with the pain. It is refractory to analgesics of all types, including morphine. In this respect, the sensation is similar to causalgia. When approached, the patient become fearful and shows a grimacing or withdrawal out of proportion to the degree of the applied stimulus.

Sensory

Paroxyms of hypersensitivity to sensory stimulation occur sometimes of such severity as to prevent the clinician from doing an adequate sensory examination. Usually slight elevation of the sensory threshold for selected sensory modalities also occur. Upon painful stimulation, the sensation is referred widely around the point of stimulation. Stimulation with heat, cold, pain or touch leads to a more unpleasant sensation than is found using the same stimulus in an unaffected area. There is a longer delay between the time of stimulation and when it is appreciated. The pain brought about by a certain stimulus may persist and far outlast the duration of stimulation.

Motor

A severe motor deficite is often lacking; the presence of severe paresis actually argues against the painful condition of thalamic origin,[4,11] although mild hemiparesis is common.

Other signs and symptoms are less constantly seen in this syndrome. Caudal thalamic lesions may extend rostrally and lead to dissociated movements of the face. The lower part of the face on the contralateral side may remain immobile as a mask when the patient laughs or cries, but contracts readily with volitional movements. The loss of emotional expression may be due to interruption of the reflex pathway extending from the thalamus to subcortical or extrapyramidal nuclei. The reverse reaction is seen in some cases with internal capsular hemiplegia: an inability to perform voluntary facial movement with preservation of the ability to smile.[2,6]

*Neurology Service, Minneapolis Veterans Hospital.

Faulty Localization

The disturbances of sensibility on the contralateral side of the body are manifest primarily by ataxia, astereognosis, diminished two-point discrimination,[2] and faulty localization of various sensory stimuli, which is felt to arise from involvement of thalamic nuclei which relay to the parietal cortex. There is tactile inattention, manifest in its most severe form by amerognosia in which the involved arm or arm and leg are ignored. Amerognosia is the sensory counterpart of anosognosia which is unawareness of hemiparesis. An identical syndrome may occur in lesions confined to the parietal lobe.[6] In the thalamic syndrome there is also decreased appreciation of posture and passive movement which leads to a decreased weight appreciation on the affected side. Stereognosis is decreased because of defects in touch, pressure and position.[2]

Dyskinesia

The ataxia, greater in the upper than the lower extremities, may be due to sensory losses or disruption of the cerebellorubrothalamic connections. Muscle tone may be diminished, but slight spasticity is found associated with mild hemiparesis due to involvement of part of the internal capsule by lateral spread of the lesion. The thalamus is close to the pallidum and, in the thalamic syndrome, involuntary movement of a choreoathetoid nature is often seen and tends to be more marked in the upper extremity. An intention tremor of large amplitude may result from disruption of rubrothalamic connections.

In vascular lesions of the thalamoperforating arteries, one encounters

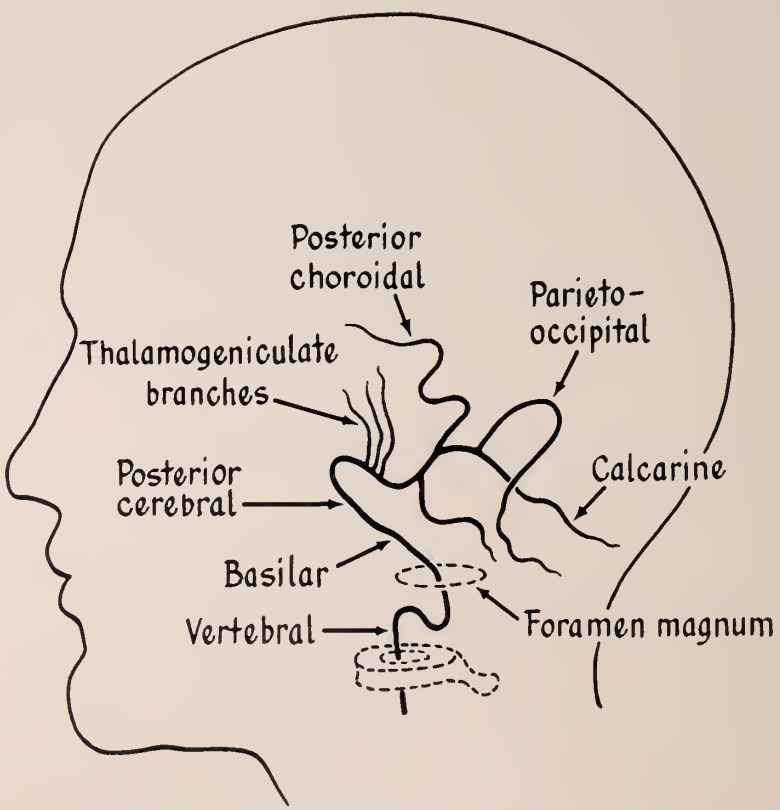

Figure 1

ataxia and involuntary movements of the opposite upper limb with the fingers and hand frozen in a choreoathetoid posture. If vascular lesions affect the pulvinar, and especially the lateral geniculate body, homonymous quadrantic or hemianoptic defects will be found in the contralateral visual fields.[2]

Physiologic Considerations

There are a number of physiologic considerations in understanding the thalamic pain syndrome. Dejerine and Roussy believed that the lesions causing thalamic pain resulted from occlusion of the thalamogeniculate artery, which is a branch of the posterior cerebral artery (Figure 1) and supplies the posterolateral portion of the thalamus, the anterior part of the pulvinar and the geniculate bodies.[2] Head[5] and others found softening of the posterolateral thalamus alone in patients who had had the classic thalamic syndrome.

Vascular

Conditions which may give rise to thalamic lesions include hypertension, arteriosclerotic disease, embolization, luetic arteritis, intracranial aneurysms and arteriovenous malformations. Neoplasms rarely produce the thalamic syndrome. Symptoms very similar to the thalamic pain syndrome may result from many other lesions, including lesions of peripheral nerves, the spinal cord, medulla, midbrain and the parietal region of the cortex.[11]

Nerve

Experimental and clinical investigations have led investigators to the fol-

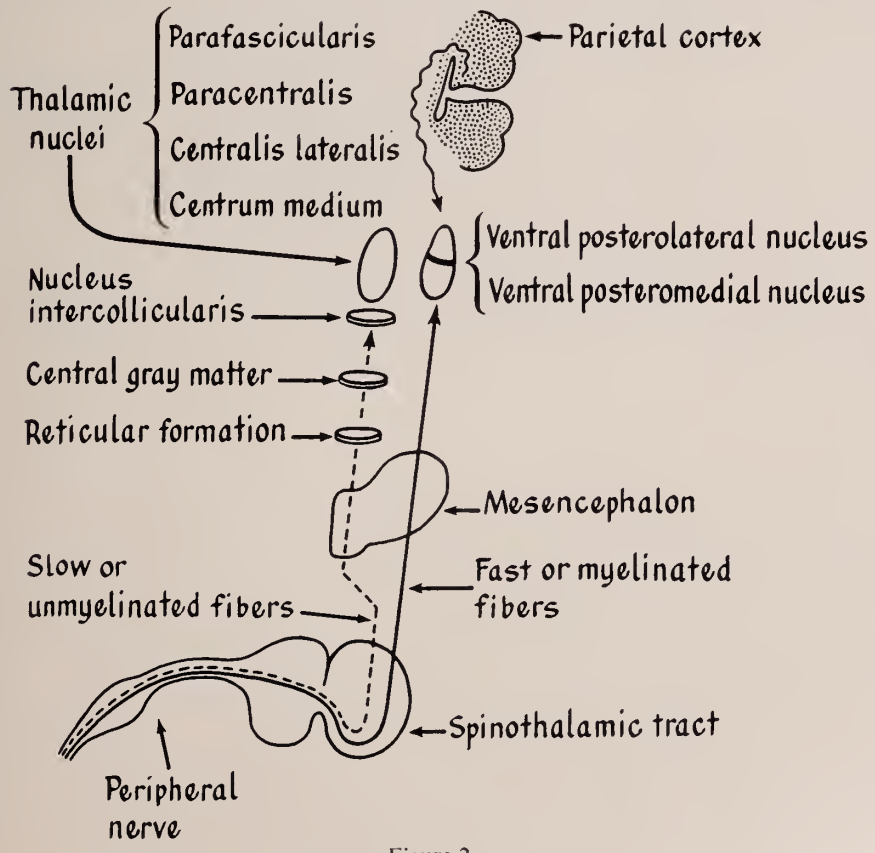

Figure 2

lowing conclusion regarding the physiology and mechanisms of thalamic pain:

There are two systems serving pain function. One is the slow or extralemniscal or paleospinothalamic; the other is the fast or lemniscal or neospinothalamic system[11] (Figure 2).

Slow pain is mediated over high-threshold, fine, unmyelinated fibers less than 2 microns in diameter to the medial or paleothalamus, at rates of 0.6 to 2.0 m/sec. Slow pain is usually described as a disagreeable burning, gnawing or boring sensation. These fine unmyelinated fibers are intermingled with the large, myelinated, fast pain fibers in the peripheral nerves and spinothalamic tract of the spinal cord. The unmyelinated fibers course through the reticular formation and, via polysynaptic pathways, through central gray matter to nucleus intercollicularis. From this site they reach the parafascicularis, paracentralis and centralis lateralis thalamic nuclei.[11] Lesions in the parafascicularis and interlaminar nuclei lead to relief of thalamic pain with only minimal or no sensory loss.[11]

Fast pain is mediated over myelinated fibers 2-4 microns in diameter at rates of 10 m/sec. These fibers have a lower threshold. This type of pain is sharply circumscribed as to location and type of stimulus and is less disagreeable than slow pain. The fast pain fibers are also intermingled in the peripheral nerves and spinothalamic tract of the spinal cord but course to the mesencephalon and thence to the ventral posterolateral nucleus of the thalamus. Lesions in the ventral posterolateral or the ventral posteromedial nucleus lead to inability to circumscribe an area of pain or other sensation, but the pain is perceived over a poorly defined area.

Evidence of slow and fast pain systems has led investigators to the conclusion that the fast pain system exercises some control or suppression mechanism over the slow pain system under normal circumstances. It is felt that the impulses from the ventral posterolateral nucleus exert an inhibitory effect on the slow pain system at the level of the medial thalamus (centrum medium and parafascicularis). The loss of input from either the periphery or cortex to the ventral posterolateral nucleus or a lesion in the ventral posterolateral nucleus can cause the thalamic pain syndrome.[11] Recent investigation has also suggested that lesions in the mesencephalon may give rise to painful sensations which may account for spontaneous paroxysms of pain. Inhibitory feedback from the cortex and thalamus may be abolished and give rise to hyperesthesia.[10]

Treatment

Thalamic pain is resistant to therapy. Some patients find relief with the use of a tranquilizing drug (phenothiazines) with diphenylhydantoin or carbamazepine plus supportive psychotherapy. Neurosurgical approaches for this type of pain have led to the interruption of the fibers in the supraclaustral area leading from the thalmus to the postcentral gyrus. This procedure avoids the hyperpathia and dysesthesia which sometimes appear after operations on the mesencephalon or thalamus. The operation is very difficult and endangers important motor and sensory pathways; transient motor and sensory deficits may occur following surgery. About 4% of these patients develop hemiparesis or ataxia postoperatively and 3% show dysesthesia and hyperesthesia. The mortality of stereotaxic thalamotomy varies from 2 to 7.5%. Therefore this type of treatment is reserved only for those who are resistant to all other approaches. Complete or nearly complete pain

relief is attained in 70% of patients undergoing surgery, but there is a 50% recurrence of the pain over a period of months to years. When a strong emotional component is present, Spiegel and Wycis[1] recommend a mesencephalothalomotomy with removal of the dorsal medial nucleus of the thalamus as well as interruption of the pathway to the postcentral gyrus. Some surgeons have treated patients by producing lesions in other thalamic nuclei. Mark et al.[8,9] found lesions of the ventral posterolateral or the ventral posteromedial nucleus led to loss of the ability to circumscribe the area of pain; but these patients continued to have a diffuse burning type pain. Lesions in the parafascicularis and intralaminar nuclei, on the other hand, produced pain relief without sensory deficits.[7,8,9]

Conclusion

The thalamic pain syndrome is a disagreeable burning sensation on the side contralateral to a thalamic lesion. The destruction is usually secondary to thrombosis of the thalamogeniculate artery, or branches leading to it. The pain sensation results when impulses mediated by the fine unmyelinated slow-conducted fibers are uninhibited. These impulses are normally inhibited by fibers from the ventral posterolateral and ventral posteromedial nuclei, the termini of large, well myelinated fast-conducting pain fibers.

Clinical Decision Making*

Some Practical Problems and Theoretical Considerations

DAVID SPENCER, M.D.

Benjamin Johnson has said that, "If all possible objections to a project are first overcome, no project will ever be undertaken". In a sense this comment is apropos to clinical decision making and an analysis of clinical judgment. In attempting to develop information concerning clinical judgment with a view towards developing a teaching methodology to encompass this subject, it becomes evident that there are certain characteristics of good judgment which can be delineated and, hopefully, can be taught.

Clinical Set

One of the tools which we will be applying to this kind of study will be that of set theory.[1] One of the concepts which we feel is helpful is the idea of a clinical set. We might define a clinical set as a given number of patients who have signs and symptoms which can be measured and quantified in such a way that they can all be described as having the same clinical problem. This is saying that they suffer from the same disease except it implies that we define the signs and symptoms arbitrarily which we will use to define this disease entity in a given group of patients. One of the problems which good clinicians have appreciated for centuries is that disease as such may have a spectrum of manifestations, a spectrum of signs and symptoms, and that precise identification of a disease at a given time can be an extremely difficult process.

An example of this might be to talk about carcinoma of the prostate without carefully defining what signs and symptoms you identify as being diagnostic of this disease. A nodule in one lobe as opposed to low back pain from widespread dissemination could lead to great differences in clinical decision making in terms of treatment, operative procedures, drug applications, morbidity, disability or mortality studies. As an example of a disease upon which a clinical spectrum might easily be agreed upon, the simple problem of nosebleed was chosen.

Nosebleed Problem

In analyzing the problem of nosebleed, we felt that some degree of agreement could be reached as to the presence or absence of a distinguishing sign (i.e., visible bleeding). Bleeding is a hallmark that all clinicians accept as evidence of the disease. This may been so elementary as to be humorous, but it is a concept which is essential to decision making.

The analysis of the nosebleed problem requires identification of the various decision points with respect to treatment and identification of all options for treatment which lead to the various outcomes associated with this medical problem. A flow diagram is useful to chart the decision process involved in treating nosebleed. We found it useful to start our analysis at the earliest possible time (with respect to the natural history of the disease process) at which a contact between physician and patient could occur. This was judged to be the telephone contact which very frequently results in the initial treatment decision made by the physician.

The physician might ascertain at this point answers to some or all of the questions listed in Table 1 before making a decision as to seeing the patient at the hospital, recommending self treatment at home, or recommending an office call. In terms of attempting to quantify the amount of bleeding in order to decide between home treatment, office call or hospital, he might apply the criterion prescribed in Table 2. Assuming that the physician felt that the patient could achieve control of bleeding with home treatment, he would decide against either an office visit or hospitaliza-

*Outgrowth of a seminar held in the Department of Family Practice and Community Health, University of Minnesota, Minneapolis, directed by Dr. Vernon Weckwerth as principle discussant and Dr. Ben Fuller as Chairman of the Department. Mr. Clyde Neu, Eric Dardinger and the author prepared this paper as an extension of this seminar.

ion. If bleeding continued, he would be faced with . second decision (decision No. 2). At this point e might obtain additional information pertinent o this particular nosebleed. Let us then assume hat the physician feels an office call is indicated. Vhen the physician sees the patient in the office, e is faced with a decision which we refer to in he flow diagram (Figure) as decision 3.

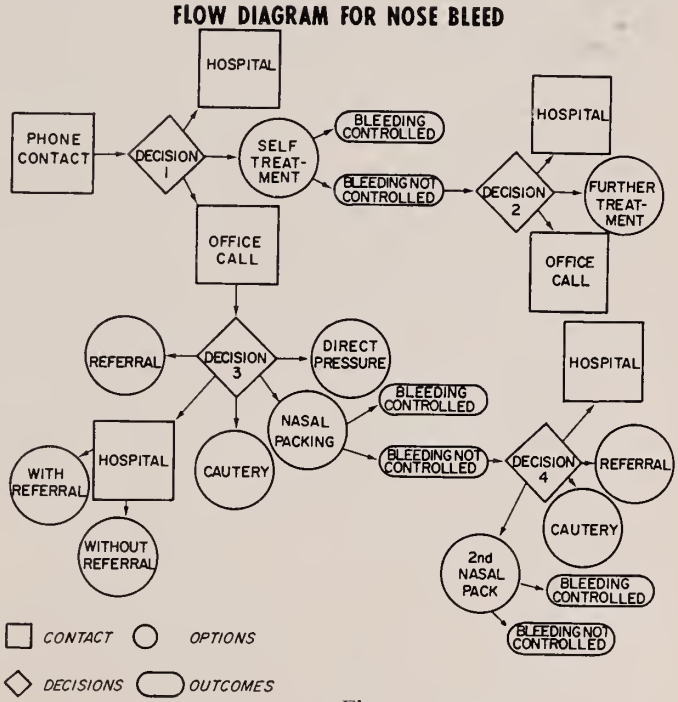

TABLE 1
Clinical Data Base for Nosebleed

1. Is this the first episode of nosebleed?
2. Is this the first time the patient has phoned?
3. How old is the patient—older than age 65?
4. Has any treatment been attempted?
5. Has there been any trauma or bone breakage?
6. Has the patient had a previous episode in last 30 days?
7. Is the patient able to make a judgment concerning duration and amount of flow?
8. Is the patient taking any medicine (anticoagulants)?
9. Does the patient suffer from any other serious disease?
10. Does the patient have any disturbance in coagulation?
11. Is the patient or a parent unusually anxious about the bleeding?
12. Has the climate or season of the year or recent URI predisposed to bleeding?

Some of the options at decision 3 that the physician has available are outlined in the flow diagram. Let us next assume that he chooses the option of nasal packing. The outcome from that decision may be that the bleeding is controlled or hat the bleeding is not controlled. If not controlled, he is faced with decision 4 and again with number of options for treatment. By applying he flow diagram and the decision tables to the reatment of a very common problem such as osebleed, we are able to follow the pathway of he logic of the physician in handling this particular nosebleed. By this kind of analysis, it is hoped hat we will be able to follow the pathway of the decision logic which the student or resident exercise in the given clinical situation. We hope that ltimately we may be able to establish probabilities and outcomes on the various pathways, so hat we can teach some idea of the best and most logical pathway and perhaps the most successful pathway from the standpoint of problem solving.

When we review the problem of nosebleed, it points to the fact that much of the medical literature is written without careful consideration as to the natural history of the problem, or the exact point at which the problem is encountered by the clinician. Hence, we are able to find papers advocating as treatment of nosebleed application of nasel packing in all instances,[2] the absolute avoidance of nasal packing in all but a very few instances, controlled hypotension,[3] injection of lidocaine with epinephrine[4] or the ligation of the external carotid artery or the ophthalmic arteries.[5]

In attempting to teach correct therapy, one can see that it is essential that a clear statement of the etiology, duration, severity and many other clinical factors should be made. Too often, the discernment of this information which has to be the basis of decision making has been left to the judgment of the student. If his only experience base has been in an emergency room or in an

Figure

TABLE 2
Decision Criterion—Duration and Flow of Bleeding

Duration of Bleeding	Under ½ hr	½-1 hr	1-2 hr	2-8 hr	Over 8 hr
Flow: Maximum	Home	Home	Office	Office	Hospital
Moderate	Home	Office	Office	Hospital	Hospital
Excessive	Office	Office	Hospital	Hospital	Hospital

Combination of duration and flow measures indicates whether patient is to be treated at home, in the office, or in the hospital. Minimum bleeding is an intermittent and light flow. Moderate bleeding is a continuous but light flow. Excessive bleeding is a continuous and heavy flow.

ENT clinic, it is obvious his ability to make effective decisions about a given clinical encounter would be markedly limited.

Before the clinician can be expected to make an appropriate decision as to the treatment of nosebleed, it is easy to see that we must teach something about the total set: the natural history of nosebleed, the total number of nosebleeds that a clinician as a primary physician might be expected to encounter, the percentage of those that follow a pathway other than the expected course of prompt subsiding of bleeding with the natural control mechanisms. If we can teach something of the natural history of this clinical problem, it will be much simpler for the student to make good decisions concerning the treatment of nosebleed. This example may seem so completely obvious as to be trivial to most of the readers of this paper. However, as we look at the educational task confronting us as we teach clinicians, particularly in the area of family practice, it becomes obvious that methods, frameworks and displays of decision processes have to be made available to the student during his training period.

Let us just cite one other example that points to this need for model decision making. Our group in discussing medical decision making attempted to tackle the problem of peptic ulcer disease; taking a group of five clinicians with a total experience base of approximately 75 years. We were unable to discuss the issue of peptic ulcer until we separated the entity of peptic ulcer disease into at least two component parts, that of gastric and duodenal. Once we had carefully identified which one of these two conditions we were talking about, it was easy for us to proceed along a decision pathway.

A simple question in treating ulcer disease is whether or not a follow-up xray is necessary. This question in terms of peptic ulcer disease is unanswerable; in terms of gastric ulcer, the answer is yes; in terms of duodenal ulcer, the answer is considerably less absolute. It may depend upon the success of the therapy, the psychological attitude of the patient, his conformity to the treatment regimen and many, many other variables. It would appear that much of our literature dealing with peptic ulcer disease serves a pointless and useless purpose in that clinical decision making to be meaningful has to be based among other factors on the position of the ulcer.

This is but one example of the myriad of clinical problems in which a knowledge of the natu history of the disease process and careful eval tion as to whether that disease represents a sin clinical set or is part of a continuum of a clini problem will be extremely helpful. In the train of the medical student towards fruitful decisi making, the point is that by developing models decisions in which we show an optimal resoluti of a clinical problem or an optimal treatment f a given disease process perhaps we can teach method of problem solving. Perhaps we can al markedly refine our ability to delineate precis clinical problems and place them in such sets categorize them in such ways that data relating the decisions that have been made concerni treatment of these processes can be stored, r trieved, and analyzed retrospectively.

It may seem ridiculous to the experienced clir cian to say that treatment of nosebleed in eve instance demands packing. Yet, if the only set patients with nosebleeds that the clinician se are those referred to a specialty clinic, packir may be the most appropriate approach. Certainl were we able to clearly outline the total spectru of many common diseases and to clearly ascerta the natural history of these diseases, the proble confronting the primary physician would be mark edly simplified.

One of the clear problems that is evident i much of medical literature today is that the pr ary physicians who are on the first line of contac in many of the very common clinical diseases ha been unable to write or to collect data in a mean ingful way so as to make it available for teachin or for analysis by students who are training t move into areas of primary care. This failure i part of the breakdown of dialogue between th clinician and the specialist in modern medicine Certainly any system of problem analysis whicl will help the student to relate to this difference o background and difference of understanding o sets of common diseases would be extremely help ful as a teaching and learning mechanism. It i for this reason that our Department has been in terested in pursuing the possibility of this kind o data acquisition and the development of a mode towards teaching clinical decision making. Hope fully, then, some of what is referred to as the ar of medicine, the mystique of a competent primary physician, may be brought into a teachable, analyzable, scientifically oriented spectrum wherein students may be as intrigued and enthused as were our predecessors in watching the Oslers and Plummers of their time.

The girth control pill

Tepanil® Ten-tab®

(continuous release form)

diethylpropion hydrochloride, N.F.)

When girth gets out of control, TEPANIL can provide sound support for the weight control program you recommend. TEPANIL reduces the appetite—patients enjoy food but eat less. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation.

Contraindications: Concurrently with MAO inhibitors, in patients hypersensitive to this drug; in emotionally unstable patients susceptible to drug abuse.

Warning: Although generally safer than the amphetamines, use with great caution in patients with severe hypertension or severe cardiovascular disease. Do not use during first trimester of pregnancy unless potential benefits outweigh potential risks.

Adverse Reactions: Rarely severe enough to require discontinuation of therapy, unpleasant symptoms with diethylpropion hydrochloride have been reported to occur in relatively low incidence. As is characteristic of sympathomimetic agents, it may occasionally cause CNS effects such as insomnia, nervousness, dizziness, anxiety, and jitteriness. In contrast, CNS depression has been reported. In a few epileptics an increase in convulsive episodes has been reported. Sympathomimetic cardiovascular effects reported include anes such as tachycardia, precordial pain, arrhythmia, palpitation, and increased blood pressure. One published report described T-wave changes in the ECG of a healthy young male after ingestion of diethylpropion hydrochloride; this was an isolated experience, which has not been reported by others. Allergic phenomena reported include such conditions as rash, urticaria, ecchymosis, and erythema. Gastrointestinal effects such as diarrhea, constipation, nausea, vomiting, and abdominal discomfort have been reported. Specific reports on the hematopoietic system include two each of bone marrow depression, agranulocytosis, and leukopenia. A variety of miscellaneous adverse reactions have been reported by physicians. These include complaints such as dry mouth, headache, dyspnea, menstrual upset, hair loss, muscle pain, decreased libido, dysuria, and polyuria.

Convenience of two dosage forms: TEPANIL Ten-tab tablets. One 75 mg. tablet daily, swallowed whole, in midmorning (10 a.m.). TEPANIL. One 25 mg. tablet three times daily, one hour before meals. If desired, an additional tablet may be given in midevening to overcome night hunger. Use in children under 12 years of age is not recommended.

Painful night leg cramps...

unwelcome bedfellow for any patient– including those with arthritis, diabetes or PVD

- □ Prevents painful night leg cramps
- □ Permits restful sleep
- □ Provides simple convenient dosage — usually just one tablet at bedtime

Prescribing Informotion — Composition: Eoch white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indicotions:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associoted with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis ond stotic foot deformities. **Controindications:** Quinamm is contraindicated in pregnoncy because of its quinine content. **Precoutions/Adverse Reactions:** Aminophylline moy produce intestinal cramps in some instonces, ond quinine moy produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rosh, or visuol disturbonces occur. **Dosoge:** One tablet upon retiring. Where necessory, dosage may be increased to one tablet following the evening meol ond one tablet upon retiring. **Supplied:** Bottles of 100 ond 500 tablets.

Specific therapy for night leg cramps.

the compound analgesic that calms instead of caffeinates

In addition to pain, this patient has experienced anxiety, fear, embarrassment, anger, and frustration. It's very likely that these psychic factors actually accentuated his perception of pain. Surely the last thing he needs is an analgesic containing caffeine. A much more logical choice is Phenaphen with Codeine. It provides a quarter grain of phenobarbital to take the nervous "edge" off, so the rest of the formula can control the pain more effectively. It's no accident that the Phenaphen formulations contain a sedative rather than a stimulant. Don't you agree, Doctor, that psychic overlay is an important factor in most of the accident cases you see?

A. H. Robins Company, Richmond, Va. A·H·ROBINS

Phenaphen® with Codeine

Phenaphen with Codeine Nos. 2, 3, or 4 contains: Phenobarbital (¼ gr.), 16.2 mg. (warning: may be habit forming); Aspirin (2½ gr.), 162.0 mg.; Phenacetin (3 gr.), 194.0 mg.; Hyoscyamine sulfate, 0.031 mg.; Codeine phosphate, ¼ gr. (No. 2), ½ gr. (No. 3) or 1 gr. (No. 4) (warning: may be habit forming).

Indications: Provides relief in severer grades of pain, on low codeine dosage, with minimal possibility of side effects. Its use frequently makes unnecessary the use of addicting narcotics. *Contraindications:* Hypersensitivity to any of the components. *Precautions:* As with all phenacetin-containing products, excessive or prolonged use should be avoided. *Side effects:* Side effects are uncommon, although nausea, constipation and drowsiness may occur. *Dosage:* Phenaphen No. 2 and No. 3—1 or 2 capsules every 3 to 4 hours as needed; Phenaphen No. 4—1 capsule every 3 to 4 hours as needed. For further details see product literature.

(III) Phenaphen with Codeine is now classified in Schedule III, Controlled Substances Act of 1970. Available on prescription and may be refilled 5 times within 6 months, unless restricted by state law.

Snifter working again

For upper respiratory allergies and infections including the common cold, Dimetapp Extentabs® effectively relieve the stuffiness, drip and congestion all night and all day long on just one Extentab every 12 hours. For most patients drowsiness or overstimulation is unlikely.

prescribing information appears on next page

A·H·ROBINS

A. H. Robins Company
Richmond, Va. 23220

Dimetapp Extentabs®

Dimetane® (brompheniramine maleate), 12 mg., phenylephrine HCl, 15 mg., phenylpropanolamine HCl, 15 mg

Dimetapp Extentabs®

INDICATIONS: Dimetapp Extentabs are indicated for symptomatic relief of allergic manifestations of upper respiratory illnesses, such as the common cold, seasonal allergies, sinusitis, rhinitis, conjunctivitis and otitis. In these cases it quickly reduces inflammatory edema, nasal congestion and excessive upper respiratory secretions, thereby affording relief from nasal stuffiness and postnasal drip.
CONTRAINDICATIONS: Hypersensitivity to antihistamines of the same chemical class. Dimetapp Extentabs are contraindicated during pregnancy and in children under 12 years of age. Because of its drying and thickening effect on the lower respiratory secretions, Dimetapp is not recommended in the treatment of bronchial asthma. Also, Dimetapp Extentabs are contraindicated in concurrent MAO inhibitor therapy.
WARNINGS: *Use in children:* In infants and children particularly, antihistamines in overdosage may produce convulsions and death.
PRECAUTIONS: Administer with care to patients with cardiac or peripheral vascular diseases or hypertension. Until the patient's response has been determined, he should be cautioned against engaging in operations requiring alertness such as driving an automobile, operating machinery, etc. Patients receiving antihistamines should be warned against possible additive effects with CNS depressants such as alcohol, hypnotics, sedatives, tranquilizers, etc.
ADVERSE REACTIONS: Adverse reactions to Dimetapp Extentabs may include hypersensitivity reactions such as rash, urticaria, leukopenia, agranulocytosis and thrombocytopenia; drowsiness, lassitude, giddiness, dryness of the mucous membranes, tightness of the chest, thickening of bronchial secretions, urinary frequency and dysuria, palpitation, hypotension/hypertension, headache, faintness, dizziness, tinnitus, incoordination, visual disturbances, mydriasis, CNS-depressant and (less often) stimulant effect, anorexia, nausea, vomiting, diarrhea, constipation, and epigastric distress.
HOW SUPPLIED: Light blue Extentabs in bottles of 100 and 500.

In Memoriam

Earth has no sorrow that heaven cannot heal.—Moore

ARCHABALD L. ARENDS, M.D.

Dr. Archabald L. Arends, 89, Minneapolis physician died November 11. A graduate of Northwestern University Medical School, Dr. Arends first practiced at Casselton, North Dakota.

He was a member of the American Medical Association and the Hennepin County Medical Society and a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Arends is survived by his wife, Evelyn.

MILTON H. SEIFERT, M.D.

Dr. Milton H. Seifert, Sr., who practiced medicine in the Lake Minnetonka area for 35 years, died November 13. He was 67. He began the Seifert Clinic in Excelsior in 1930, the year after graduating from the University of Minnesota Medical School.

He was a member of the Hennepin County Medical Society, the American Medical Association and an Associate Member of the Minnesota State Medical Association.

Dr. Seifert is survived by a daughter, Mary, and six sons, three of whom are physicians, Doctors Milton H. Seifert, Jr., Gregory L. Seifert and John D. Seifert.

RICHARD P. NEARY, M.D.

Dr. Richard P. Neary, 63, Minneapolis physician died November 6. He was head physician in the Outpatient Services Department of St. Mary's Hospital and a former president of the Hospital's Medical Staff. He had been in general practice for 38 years and on the St. Mary's staff for 20 years. A graduate of the University of Minnesota Medical School, Dr. Neary interned at Hennepin County General Hospital.

He was a Fellow in the American Academy of General Practice, a member of the Minnesota State Medical Association, the American Medical Association, the Hennepin County Medical Society and the American Association of Railroad Surgeons.

He is survived by his wife, Winifred, three daughters and three sons, one of whom is Dr. Michael Neary.

NICHOLAS F. MUSACHIO, M.D.

Dr. Nicholas F. Musachio, 59, physician at the University of Minnesota Health Service, died September 16. Dr. Musachio formerly served as chief of staff of St. Cloud Hospital and as president of the Stearns-Benton County Medical Society.

A graduate of the University of Minnesota Medical School, Dr. Musachio was also a former president of the Benton County Tuberculosis and Health Association, local surgeon for the Great Northern Railway, member of the Stearns-Benton County Medical Society, the Minnesota State Medical Association, the American Medical Association, the American Academy of General Practice and the American Geriatric Society.

Dr. Musachio is survived by his wife, Phyllis, five daughters and a son.

MALCOLM B. HANSON, M.D.

Dr. Malcolm B. Hanson, 73, Minneapolis radiologist, died September 1. A graduate of the University of Cincinnati College of Medicine, Dr. Hanson started practicing in Minnesota in 1937.

He was a member of the Hennepin County Medical Society and the American Medical Association and an Associate Member of the Minnesota State Medical Association.

Dr. Hanson is survived by his wife, Josephine.

LOUIS R. KOLLER, M.D.

Dr. Louis Koller, 81, ear, nose and throat specialist for over 50 years, died December 4. He continued to practice medicine until his death.

A graduate of St. Louis University Medical School, Dr. Koller was a member of the American Academy of Ophthalmology and Otolaryngology, American College of Surgeons, Hennepin County Medical Society and the American Medical Association. He was a Life and 50 Club Member of the Minnesota State Medical Association.

Dr. Koller is survived by his wife, Emilie, sons, Dr. Robert Koller of Minnetonka and John of Albuquerque and daughters Donna and Mrs. Joan Kongsvik, Jr.

MELVIN P. BAKEN, M.D.

Dr. Melvin P. Baken, Sr., 77, who was a practicing physician in Minneapolis for 50 years, died November 28. He was the former chief of staff at Fairview Hospital.

He was a member of the American College of Obstetrics and Gynecology, Minnesota Obstetrics and Gynecological Society, the American Medical Association and the Hennepin County Medical Society. Dr. Baken was also a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Baken is survived by his two sons, Richard J and Dr. Melvin P. Baken, Jr. of Edina.

Alcoholism

R. O. HEILMAN, M.D.*

MEDICAL SCIENCE now recognizes that alcoholism is a form of drug dependency. Symptoms can be recognized early, before the actual observation of the person's attitudes and behavior when drinking. It is generally accepted that how often a person drinks or how much he drinks are unreliable indexes for determining the existence or the non-existence of alcoholism. The crucial factor in recognizing an alcoholic, and especially the younger alcoholic, is how he uses alcohol. Generally, male alcoholics develop an alcoholic drinking pattern within three years after their first experience with "getting high." This is also true for 70% of the alcohol-addicted women. Other addictive agents result in psychological habituation and physical addiction in a much more rapid fashion; this is probably part of the reason that physicians have been slow in recognizing some of the early symptoms of alcoholism.

From experience in alcoholic treatment centers, psychiatric hospitals, and from the self-report of addicted individuals, we know that there are some symptoms of alcoholism surrounding the patterns of drinking which are characteristic of the addicted individual. This is true of all alcoholics within the United States regardless of age.

The general characteristics of alcoholics are: preoccupation with alcohol, increased tolerance to alcohol, gulping drinks, drinking alone, using alcohol as a medicine, blackouts, protecting the supply, and unpremeditated drinking. An individual is considered to be an alcoholic when four or more of the above characteristics exist. While there is some dispute as to an exact definition of each of these symptoms, they are usually described in the following manner.

The alcoholic is usually preoccupied with the next time he will be able to drink. He thinks about drinking at inappropriate times and at times when he should be concerned about other matters. Preoccupation with the experience of "getting high" is the indication of any kind of drug dependency.

Research has substantiated that increased tolerance to alcohol is characteristic of the young alcoholic. Such an individual can drink up to five times as much as a social drinker, and in the first hours of drinking this individual will report stimulating rather than sedative effects of the drug. The reason for this difference in reaction to alcohol is unknown but has been reported frequently.

As with other drug dependencies a person takes the drug for its effect and, therefore, will attempt to acquire as much as possible in the shortest possible time. Gulping drinks is characteristic of an alcoholic individual. He usually orders a double Martini, double Manhattan, a double shot, etc., because his primary intention in drinking is to "get high." This is the goal of any drug dependent person and the experience he becomes "hooked on."

Drinking alone is not diagnostic in itself, but most social drinkers drink merely to be social. Sociability is not an important factor in addictive drinking, and an alcoholic will drink at home when no one else is drinking. He will stop in a bar and drink by himself and will otherwise drink in situations where the only possible pleasure is the alcohol itself.

Once an alcoholic recognizes the exceptionally rewarding effects of alcohol, he often thinks of alcohol as a sort of panacea. He will use it as a medicine and especially as a tranquilizer for tension, anxiety, or sedation. Most alcoholics will think of alcohol when they are suffering from any form of disagreeable symptom or psychological stress.

Blackouts are a form of amnesia. On the morning after a heavy drinking bout the alcoholic has difficulty recalling some of the events of the previous evening. He may wake up and not be able to recall when he returned home or may not be able to remember some of the later events of the previous evening.

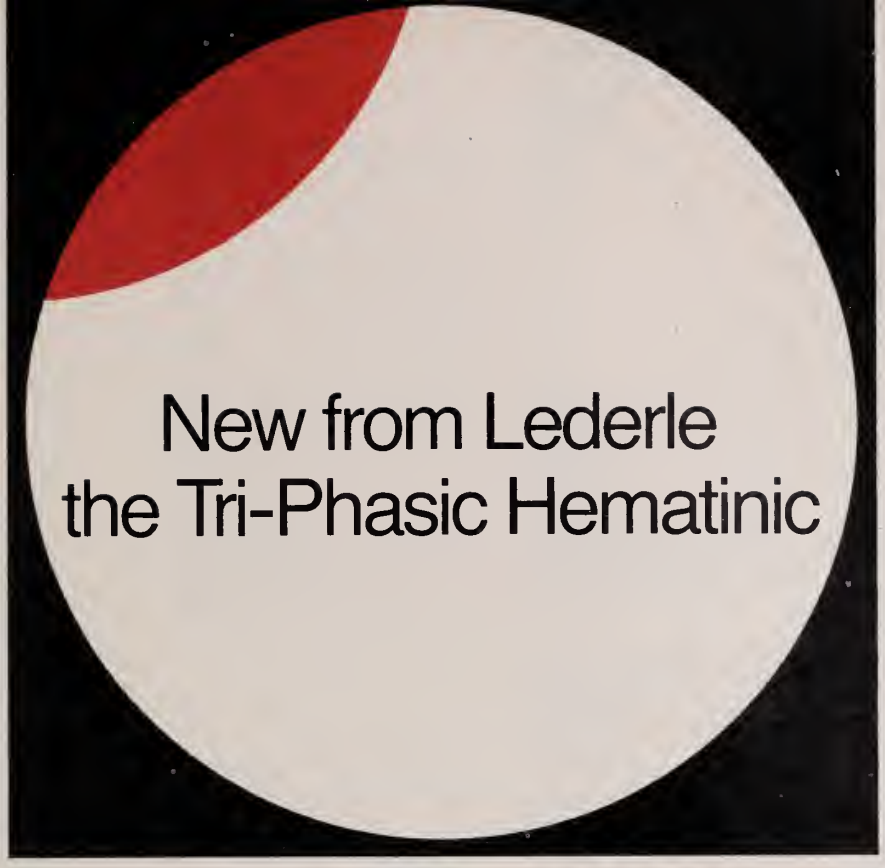
Sometimes the alcoholic feels more comfort-

*Veterans Hospital, Minneapolis, Minnesota.

able if he knows that alcohol is available. He feels reassured when he knows that there is sufficient alcohol at home, in the trunk of his car, in his office, or in his desk, in the event that he may need a drink sometime. Preoccupation with having a sufficient supply on hand is a trait of any drug dependency.

The alcoholic drinks more than he planned or knows he should drink. His drinking is often different than he would like it to be. As an example he may lose control on one or more occasions; he may stop for one or two drinks on the way home and end up intoxicated. Anyone who responds positively to the question: "Is your drinking any different than you would like it to be?" is probably suffering from alcoholism.

As mentioned before, if a person has four or more of the above eight symptoms, there is no question that he is an alcoholic because he has affected a predominately non-social use of alcohol, the end of which is to "get high" and, consequently, an obvious manifestation of psychic dependency on alcohol. Once a person has a drinking pattern as listed above he will not be able to successfully alter or change this pattern no matter how or what he tries. His only recourse is total abstinence, for if he continues to drink the consequences he will encounter physically, psychologically, socially, maritally, economically, and vocationally are definitely predictable. The pattern of drinking described above is acquired by the alcoholic through experimentation with alcohol whereby he achieves the optimum desired response. Because there is no definite standard of normal drinking in our society and, consequently, no education as to what is an alcoholic type of use, the alcoholic simply does not know that his drinking is abnormal or different from others. The physician alerted to these eight symptoms and signs can help the alcoholic by recognizing his chemical dependence. It follows that once his chemical dependence is recognized, the appropriate treatment measures can be instituted. Since the estimated number of alcoholics range as high as one in ten males and one in fifty females who drink, it is sufficient to note that medical management cannot possibly be instituted in all of these individuals.



Group therapy through Alcoholics Anonymous, specialized alcohol treatment programs in general hospitals, and specialized treatment centers outside of general hospitals are increasingly being used as resources in the community. These have been successful because they focus on the addiction and what to do about it rather than analyzing its cause.

The biggest danger physicians face in treating alcoholics is in prescribing ataractics or tranquilizers which are potentially habit forming. Librium*, Equanil*, Valium*, Serax*, the barbiturates, and other drugs are potentially habit forming and should not be prescribed for alcoholics. Some of these agents are useful in the withdrawal phase of the seriously-addicted individual but certainly should not be used on a maintenance basis. Alcoholics, and other kinds of drug dependent people, are notorious switchers in the sense that they can switch from alcohol to a minor tranquilizer or barbiturate with great ease. Incidentally, once an individual begins using a habit forming drug other than alcohol, he usually begins drinking after a short period of time.

Conclusions

There are some early signs and symptoms the physician can look for as a guideline in diagnosing the syndrome of alcoholism. This is a true drug dependency that falls within the scope of most medical practices. Early diagnosis and referral of the addicted individual are necessary for a successful outcome. There are treatment resources in almost every community in the United States which are interested in helping the addicted individual. All physicians should use extreme care when prescribing drugs to chemical-dependent persons, especially alcoholics. The alcoholic can switch from alcohol to one of the substitutes with relative ease. The inclination of alcoholics to "swallow something" to solve their problems can be carried from the "golden glass" to the medicine cabinet and it behooves all of us to make certain that we do no harm to our patients.

LIBRIUM	brand name for CHLORDIAZEPOXIDE
VALIUM	brand name for DIAZEPAM
EQUANIL	brand name for MEPROBAMATE
SERAX	brand name for OXAZEPAM

Specifically formulated with
vitamins and minerals important
in the treatment of anemia

PHASE 1
Enhanced Absorption

Each tablet provides 115 mg elemental iron as the highly absorbable ferrous fumarate *plus* 600 mg of Vitamin C.

PHASE 2
Erythrocyte Formation

Each tablet provides Vitamin B_{12} (25 mcg) and Folic Acid (1 mg) to replace deficiencies.

PHASE 3
Premature Hemolysis

Each tablet provides Vitamin E, which may be involved in lessening red blood cell fragility.

For common anemias
as well as problem ones

TriHEMIC™ 600
HEMATINIC TABLETS

Tri-Phasic Hematinic with 600 mg Vitamin C PLUS Vitamin E

Each tablet contains:	
Vitamin C (Ascorbic Acid)	600 mg.
Vitamin B_{12} (Cobalamin Concentrate, N.F.)	25 mcg.
Intrinsic Factor Concentrate	75 mg.
Folic Acid	1 mg.
Vitamin E (*d*-Alpha Tocopheryl Acid Succinate)	30 Int. Units
Elemental Iron (as present in 350 mg. of Ferrous Fumarate)	115 mg.
Dioctyl Sodium Sulfosuccinate U.S.P.	50 mg.

Dosage: One Tablet Daily.
Available in Bottles of 30 Tablets.
On Your Prescription Only.

Precautions: Some patients affected with pernicious anemia may not respond to orally administered Vitamin B_{12} with intrinsic factor concentrate and there is no known way to predict which patients will respond or which patients may cease to respond. Periodic examinations and laboratory studies of pernicious anemia patients are essential and recommended. If any symptoms of intolerance occur, discontinue drug temporarily or permanently. Folic acid, especially in doses above 1 mg. daily, may obscure pernicious anemia, in that hematologic remission may occur while neurological manifestations remain progressive.

Adverse Reactions: G.I.: nausea, vomiting, diarrhea, abdominal pain. Skin rashes may occur. Such reactions may necessitate temporary or permanent changes in dosage or usage. Allergic sensitization has been reported following both oral and parenteral administration of folic acid.

TriHEMIC™ 600
HEMATINIC TABLETS

Tri-Phasic Hematinic with 600 mg Vitamin C PLUS Vitamin E

Specifically formulated with vitamins and minerals important in the treatment of anemias, plus a stool softener to counteract the constipating effects of iron.

Fracture Conference

Comminuted Fractures of the Femur*

MARK B. COVENTRY, M.D.,† PETER L. BOMAN, M.D.† and
EINER W. JOHNSON, JR., M.D.†

Dr. Peter L. Boman:

Our first case is that of a 77-year-old real estate agent who was in a head-on automobile collision two weeks prior to his admission at the Mayo Clinic. The driver of the other car was killed and his wife suffered a fracture of the fifth lumbar vertebra and severe abdominal contusions from her lap seat belt. The patient was initially treated in another hospital for a midshaft comminuted fracture of the left femur, a comminuted fracture of the left tibia and fibula, fractures of both bones of the contralateral forearm, and concussion and multiple facial lacerations. He also suffered two broken ribs.

After he had been treated for shock and the lacerations had been sutured, the forearm was placed in a padded, wooden splint with a pin placed through the tibia for traction. The roentgenograms made on admission here are shown in Figure 1.

*Fracture Conference, April 8, 1968.
†From the Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

Fig. 1—(Case 1). Anteroposterior (*Left*) and lateral (*Right*) views of left femur and upper tibia two weeks after injury, showing comminuted fractures of distal femur and proximal tibia.

Dr. Mark B. Coventry:

The patient was an elderly man, and we were worried about his general condition—shock, pneumonia, fat embolism—but he survived all these. His local physician had put a pin in the tibia and applied a Thomas splint. Since the time of injury we had been in touch with the local physician, who had taken excellent care of the patient and then transferred him to our service for definitive orthopedic care. The main objective is to get a functioning lower extremity, so that he can walk. How are we going to do this, Doctor Irwin?

Dr. Jack C. Irwin, Jr.:

If he were younger it might be easier to gain union by plating the lower end of the femur. As far as the tibia is concerned, I do not think one could help that much by internal fixation. I believe one should try to mold the fracture into the best possible position and then attempt to hold it by applying a cast or using traction. Traction would have the advantage of letting him move the knee. With a cast, it would probably be difficult to regain motion. For comminuted fractures, traction is probably the best method.

Dr. Coventry:

There seem to be about six fragments present. What else is available other than traction? Would you wish to open this fracture?

Dr. Irwin: That would be difficult.

Dr. Coventry:

Yes, I agree, and most difficult to rearrange and hold with any type of internal fixation. Are any other methods available?

Dr. Irwin:

You could place the extremity in a cast. One would have to reduce it under general anesthesia; but this would probably not be a good method of treatment since it would be difficult to maintain the reduction in a cast because of the degree of comminution.

Dr. Coventry:

Some shortening would probably occur. You eliminated the use of intramedullary rods, Dr. Irwin. Why?

Dr. Irwin:

The fracture is too low and too comminuted to be treated that way effectively.

Dr. Coventry:

Now, as to the tibia on the ipsilateral side, we have a pin there, well placed by the local physician, and we will not disturb it. This aligns the tibial fracture well and should be good definitive treatment. Are you concerned about the posterior bowing of the femur at the fracture site?

Dr. Irwin: Yes.

Dr. Coventry: How will we correct this?

Dr. Irwin:

You can put a folded towel under it. I would put him in a Thomas splint with a Pearson attachment to allow for flexion of the knee.

Dr. Coventry:

Correct. You would put a towel under the fracture site. Anything else? Are we going to pull this femur down with the pin below the tibial fracture? What if we should get some distraction of the tibial fragment while doing this?

Dr. Irwin: This would certainly defeat both purposes.

Dr. Coventry: How would you remedy it?

Dr. Irwin: It would probably be easier to remedy by putting a pin through the distal femur.

Dr. Coventry:

This is what we did (Figure 2). The single pin placed previously is pulling through a fractured tibia and then through the knee, and this traction is expected to transmit force to the very strong muscles of the thigh. But that is impossible. So we put a Kirschner wire through the distal fragment of the femur and put the pull on it. We also retained the pin in the tibia with only three or four pounds of weight on it. The pin in the distal femur not only maintained length and lateral alignment there but also corrected the posterior bowing by pulling anteriorly as well as distally. Do you think the bowing is overcorrected?

Fig. 2—(Case 1). Anteroposterior and lateral views of left femur after Kirschner wire had been placed through distal femur two and a half weeks after injury.

Dr. Irwin: It is a little overcorrected.

Dr. Coventry:

A little bit. So we can lessen the traction a few pounds. We are talking about alignment, and alignment means overall restoration of the contour of the femur, considering both joints involved and the natural configuration of the bone. Displacement is not alignment. We have good alignment here but also displacement of about half of the shaft in the lateral position. We do not care about this because we want only union with good alignment. We also desire restoration of length, and we have established that.

The patient was in traction for six weeks and, when he showed good callus formation roentgenographically, we put him in a spica cast (Figure 3).

Fig. 3—(Case 1). Anteroposterior and lateral views of left femur 10 weeks after injury, in spica cast.

Dr. Boman:

Initially, when we took him out of the spica cast, he had bony union but rather limited knee motion of about 25° to 30° but after a little exercise it had increased to 90° of flexion.

Dr. Coventry:

I think he is going to come along fine with the method of treatment we elected here. I am sure there are other ways of handling these fractures, but we preferred this rather conservative method. Union and a functional limb have been obtained.

Case 2

Dr. Boman:

The next case is similar. A 47-year-old man was working on a truck, straddling the saddle tanks on the side, when a car on a grease ramp rolled down and struck his left lower extremity, severely crushing it. He was taken to his local hospital where he was found to be in shock. Blood transfusion was given and he was then sent to this clinic. There was a large laceration in the popliteal area, marked swelling of the entire extremity, and fractures as shown (Figure 4).

Dr. Coventry:

These fractures are compounded and again there are fractures of the femur, tibia, and fibula of the same extremity. There is also a large, gaping wound in the popliteal fossa. We saw him within a few hours of his injury. Dr. Beckenbaugh, what do we do first?

Dr. Robert D. Beckenbaugh:

The initial treatment has to be debridement of the compound fracture,

Fig. 4—(Case 2). *Left* and *Center,* Anteroposterior and lateral views of distal left femur, showing distal fracture at time of injury. *Right,* Lateral view of left tibia and fibula at time of injury.

leaving the wound open. The tibial fracture is compounded only in the popliteal area. Is that right?

Dr. Coventry:

Yes, except for a one-cm hole with a spicule of the tibia sticking through it at the fracture site anteriorly. Thus it is minimally compounded from within. We must be sure of his vascular and neural status. His dorsalis pedis pulse was normal, but he had no peroneal nerve function. The back of the knee joint was wide open; we could look in and see the menisci. There were fractures of the tibial spines; one could put one's hand down into the calf to mid leg and up into the thigh halfway to the hip. But the popliteal artery and vein were uninjured. We did an extensive debridement, put in some drains, packed gauze loosely over the wound, and then turned our attention to the fractures. There are problems here. How would you proceed?

Dr. Beckenbaugh:

Initially, I would do nothing in the way of internal fixation of the fractures. But I agree with open packing of the wound in the popliteal area and debriding the compound fracture. I would anticipate that he would be placed in a Robert Jones type dressing, with some arrangements made for changing the pack, for two or three days before an attempt at closure of the popliteal wound and internal fixation of the tibial fractures.

Dr. Coventry:

He was fortunate in having this wound posteriorly, so it drained dependently as he lay on his back in bed. Nature was working for him. We saw no reason not to go right ahead and put in Kirschner wires for traction and place the extremity in a splint. The initial injury had created a right angle flap and we had to extend it rather widely for exposure to debride the wound. When we finished we put in some loose sutures to hold this flap over the blood vessels and so cover them.

There now is a pin through the distal fragment of the femur, and a localizer is used to control angulation laterally. How are we going to get some traction on the tibia?

Dr. Beckenbaugh:

If you think the alignment is not good enough you can put in a calcaneal wire, place the leg in a cast, and apply traction.

Dr. Coventry:

We did just as you suggested—put a pin through his os calcis; then the extremity was put in a Thomas splint with a Pearson attachment, and he was started on antibiotic therapy. After three days, we dressed the wound, took out the drains and packs, and finished up our closure using irrigation-suction tubes.

Dr. Boman:

The roentgenograms at 32 days after injury (Figure 5) show good progress; alignment is good and callus is visible.

Fig. 5—(Case 2). At 32 days after injury. *Left* and *Center*, Left distal femur. *Right*, Left tibia and fibula.

Dr. Richard S. Bryan:

There is another method for dealing with the same type of thing: utilizing a cast, attaching the pins with plaster, and using a modified Russell strap, leaving the entire posterior part open with the two pins acting as a sling.

Dr. Coventry:

During World War II, when we had so many of these injuries due to gunshot and shell-fragment wounds, we inserted pins, pulled the fractures out, aligned the limb, and put the extremity in a spica cast.

Case 3

Dr. Boman:

Our third patient suffered a fracture of the right midfemur in an automobile accident in 1929, when she was 19 years of age. Her initial treatment at that time had been a bone graft and insertion of a six-hole plate. Within a few months she had no evidence of healing and was brought here for definitive treatment. In August 1929 the plate was removed and some straightening done for the bowing of the femur.

Dr. Coventry: Was an osteotomy done?

Dr. Boman:

No, she had non-union, and the femur was manipulated back into straight alignment. In September 1929, when there was no evidence of healing, tibial grafts were inserted at the fracture site, after which good union was attained. The patient got along well until 1949, when she began to have pain in the right knee, especially on the medial aspect. This became progressively worse,

and she came here in 1956 for evaluation. There was degenerative joint disease in the right knee, especially on the medial side. By 1966 she had severe pain with activity; she had motion in her knee from 25° to 80° (Figure 6).

Fig. 6—(Case 3). Anteroposterior and lateral views of right knee 38 years after fracture of right midfemur.

Dr. Coventry:

This is 37 years after fracture. The alignment in the anteroposterior direction looks good, but there is some lateral bow (varus), as a result of which she has put abnormal stress on her knee for the last 37 years. The alignment we have been talking about this morning should be preserved at all costs because, as the years pass, malalignment produces abnormal loading stresses which may produce degenerative changes in the adjacent joints. This patient surely represents such an example.

Dr. Boman:

In April 1966, Dr. Coventry explored her knee, removed the medial meniscus, and found several loose bodies in the joint, which were removed. Then he did an upper tibial osteotomy (Figure 7). The patient did well postoperatively and by December 1966 had no pain with motion, an almost normal gait, and a range of motion from 0° to 60°. She is walking essentially pain-free, with a good gait.

Dr. Coventry:

We used the anterior approach here and retracted the patellar tendon to the right when we were doing the left side and to the left when we were doing the right side. We used two staples for fixation of the osteotomy. We went anteriorly because we wanted to take a large anterior wedge to correct the flexion deformity and convert her 60° of motion to a more useful arc. We knew we could not increase it, however. She can now put her foot down with her knee straight instead of bent at 30°. Her varus deformity is also corrected.

Dr. Emanuel Semerad:

Why do you think the medial joint had narrowed originally when her initial fracture healed with lateral bowing?

Fig. 7—(Case 3). At eight months after upper tibial osteotomy.

Dr. Coventry:

When there is lateral bowing, one gets more stress on the medial tibial and femoral condyles due to varus. If there is medial bowing, one gets valgus of the knee. With lateral bowing, as this patient has, one gets bowleg deformity; and bowleg opens the lateral compartment but loads the medial.

Dr. Boman:

On reviewing the literature, one finds many forms of treatment for multiple fractures of one extremity including intramedullary rod, plates and screws, skeletal traction, and immobilization in plaster. When one considers fractures in the distal third of the femur, one has to remember the muscle groups that come into play: the quadriceps, the adductors, the hamstrings, and the gastrocnemius. In intercondylar and supracondylar fractures the gastrocnemius muscle may produce joint incongruity by causing posterior angulation or displacement of the fracture, or by rotating and spreading the condylar fragments.

The quadriceps and hamstrings produce longitudinal forces which produce overriding and angulation of the fragments or driving of the proximal femoral fragment into the suprapatellar pouch, causing further displacement and hemorrhage.

Valgus deformity, which is frequently seen, can be caused by the strong pull of the adductor magnus and longus. Fortunately, vascular and neurologic damage in these fractures is rare but must always be watched for.

Stewart and co-workers' reviewed the experience at the Campbell Clinic with fractures of the distal third of the femur. Two hundred thirteen patients were followed for more than a year. The fractures were divided into two groups according to method of treatment: closed methods and open methods. Closed methods included skeletal traction using one or two pins, casts, simple splinting, and skin traction. An excellent or good result was defined as 130° of flexion of the knee without much pain on motion and walking without a limp. The patient with a poor result had moderate or severe pain, 90° or less flexion, and moderate or severe limp. The results of the closed methods

are shown in Table 1. Skeletal traction was used chiefly in 84 cases. The results of open treatment methods are shown in Table 2. Blade plates, Rush pins, Knowles pins and screws, intramedullary nailing, and intramedullary bone graft were used for fixation. Their biggest series was with Knowles pins and screws. Overall, results were good or excellent in 67% of cases treated by closed methods and in 54% treated by open methods.

TABLE 1
Results of Closed Treatment*

Method	Cases	Results	
		Excellent or good	Fair or poor
Skeletal			
One pin	50	33	17
Two pins	34	27	7
Casts	54	32	22
Splint	4	3	1
Skin traction	2	2	0
Total	144	97	47

*Data from Stewart and co-workers.[1]

TABLE 2
Results of Open Treatment*

Method	Cases	Results	
		Excellent or good	Fair or poor
Blade plate	12	5	7
Rush pins	8	4	4
Knowles pins	40	24	16
Intermedullary nail	7	2	5
Intramedullary bone graft	2	2	0
Total	69	37	32

*Data from Stewart and co-workers.[1]

Anderson[2] reported results of closed treatment, in both children and adults, using Russell traction. His results for adults were similar to Stewart and co-workers.[1] His article emphasized more the care of children, in which the results generally were very good, as one would expect. The technique for pin traction is relatively easy. Actually, the femoral pin does not have to be inserted immediately. It can be done 24 to 48 hours later when one sees what degree of angulation will occur. At times the periosteum and the soft tissues will maintain alignment without this pin. Figure 8 shows a patient in this type of two-pin traction.

Dr. Coventry:

Dr. Boman has well summarized the various methods of treatment for fractures of the distal femur. We have presented two cases complicated by fibiale fractures as well on the same side. In my experience, balanced traction in a Thomas splint with a Pearson attachment has worked well. The two-pin technique is surely worthy, because it gives control of the distal fragment and will overcome its tendency to flex posteriorly.

Fig. 9—Example of two-pin traction.

Careful alignment should be striven for; degenerative joint changes in the knee (or hip or ankle) may develop if bowing of the femur occurs.

Organization

AMA Membership

DESPITE STATEMENTS to the contrary by some segments of the press and certain politicians, the AMA continues to represent the majority of American physicians. At this time when the practice of medicine is facing perhaps its greatest challenges, it is vital that a strong, effective national organization be sustained.

Hopefully, every Minnesota physician will be stimulated by this brief article to give thoughtful introspection to the importance of national representation through his AMA membership.

The purpose of the AMA is "to promote the science and art of medicine and the betterment of public health."

It offers help to physicians in keeping up to date on every phase of modern medicine and serves the public in a thousand unseen ways each day.

The story of the AMA is a story of more than a century of medical progress in this nation . . . for since its founding in 1847, there has been no major public health program in the United States in which the AMA has not played a significant role. To recount all of the accomplishments and discuss all the current activities, programs and services the AMA is engaged in would require several volumes of this journal, so the following resume of AMA activities should be viewed as merely examples of how the AMA serves medicine and the nation, and how it serves you.

AMA's Organization

The AMA is a democratically organized federation of 54 states, commonwealths and territorial medical associations. These, in turn, are composed of more than 1900 component county medical societies. The representative government principle applies throughout, with authority moving up from the component societies through the state societies to the national body through the process of elected delegates. As a member of the AMA, you have a voice with your vote if you choose to exercise it in electing state delegates and thereby determining the Association's leadership and policy.

From the office at 535 N. Dearborn Street in Chicago, the AMA maintains 80 Councils and Committees. The AMA staff and nearly 1000 volunteer physicians, working without remuneration, carry out the work of the organization.

Major Areas of AMA Activities

Scientific Meetings

The AMA sponsors more than 1000 meetings a year. Its Annual and Clinical Conventions, held each June and November, are the most important postgraduate medical study sessions in the world. Postgraduate programs encompass some 400 scientific lectures under the auspices of 23 specialty sections of the AMA. The AMA has sponsored meetings, and long offered leadership in such areas as occupational health, cost and distribution of care and the fight against pollution.

Accreditation

The AMA represents physicians in the accreditation of medical schools, postgraduate education and continuing education programs. It represents the needs of physicians in the accreditation of hospitals and establishing essentials for training allied health personnel.

Ethics

One of the paramount reasons for founding the AMA was to develop an accepted code of ethical conduct for physicians. Through the Judicial Council, the AMA continues to exercise responsibility as the developer, repository and arbiter of medical ethics.

AMA Library

The Archives Library of the AMA receives in an average month over 3000 research requests from physicians and others, and 750 requests for brochures. They have over 4500 films available and send out approximately 25,000 pages of photocopied material each month.

AMA Publications

Publications are a highly important part of the Association's program. The AMA is one of the world's largest publishers and about 12 million dollars of the budget goes into paper, printing and mailing.

* *The American Medical News* has a circulation of 20 million newspaper per year.
* The AMA has available approximately 1300 different pamphlets on child care, health education, sex education, diet and nutrition,

smoking, first aid. etc.

* The AMA has mailed free over 5 million pamphlets on the "Pill."
* *Today's Health,* a consumer magazine, is published monthly by the AMA.
* 100,000 kits on drug abuse have been sent to medical societies and individual physicians.
* *JAMA*, The Journal of the American Medical Association, is the most widely circulated medical journal in the world.
* To meet the needs of the specialties, AMA publishes 10 monthly specialty journals.

These and numerous other books and publications have been asked for by the physicians of this country, the public, the schools of this nation, allied health professions, health institutions, government agencies, and the more than 1900 state and county medical societies. As a result AMA researches, designs, publishes and prints these tens of millions of pieces every year. This is the responsibility of the AMA to the physicians and to the people of this country and one which will continue to be fulfilled only by a strong membership.

AMA Law Division

One of the most active divisions of the AMA is the Law Division which supplies to all departments, the Board of Trustees and physicians throughout the country, legal opinions and guidance, information on medical liability, taxation, insurance, advertising, copyrights, etc. Tens of thousands of physicians write every year and receive guidance on these and other problems.

AMA-ERF Programs

The American Medical Association Education and Research Foundation (AMA-ERF) established in 1962 has arranged over 46 million dollars in loans to more than 19,000 medical students, interns and residents in direct contributions. The AMA has received and distributed over 35 million dollars to medical schools in this country.

AMA Department of Investigation

The Department of Investigation has one of the largest collections of nostrum and quack gadgets and medications. It maintains the largest files in existence on health quackery and wages a relentless battle against cultists and charlatans throughout the country every year.

Health Care Delivery

The AMA has sponsored many programs to provide leadership and examples in the field of health care for the poor and in field of rural health care. Among them are inner-city health centers, donations of two mobile health units to a Chicago slum area . . . financing of health care projects by the Student AMA . . . and encouragement of innovations in methods of taking care of patients in areas of need and sparse physician population.

Legislation

The AMA through its Washington office and Council on Legislation reviewed over 1500 separate bills pertaining to medicine during the past session of Congress. In the last year, the AMA appeared before Congress in support of such measures as funding for medical school expansion, increased financial aid to medical students, appropriations for hospitals and medical facilities expansion, drug abuse education, vaccination assistance programs and numerous other positive proposals. The AMA's own proposal for financial health care—Medicredit—has received wide Congressional support as it is fiscally sound and would assure availability of health care for all without endangering traditional physician-patient relationships. It is also sponsoring legislation to create Peer Review and Utilization Review systems to operate through state medical associations.

Important Congressional appearances were also related to such subjects as HMO's, National Health Insurance Bills, the National Cancer Program and many others.

This affirmative legislative stance has been well received in the present Congress as many members of the Senate and House from both sides of the aisle will attest.

In addition, AMA's representatives meet frequently with representatives of the various administrative and regulatory agencies in Washington. Proposed regulations are closely reviewed and appropriate testimony is offered.

AMA Membership and Finances

There are approximately 345,000 physicians in this country including those not actively engaged in the practice of medicine (there are 198,000 office based physicians). Current AMA membership is 205,000. Approximately 46% of the total AMA budget is derived from physician dues, the remainder, about 54% comes from advertising

and exhibit revenues. Your AMA dues of $110 would have to be about $250 were all the operational costs of the AMA to be financed by membership dollars. Further, it should be noted that of the 1972 budget over 80% will be expended for educational and scientific programs designed to improve the quality of American medicine.

Conclusions

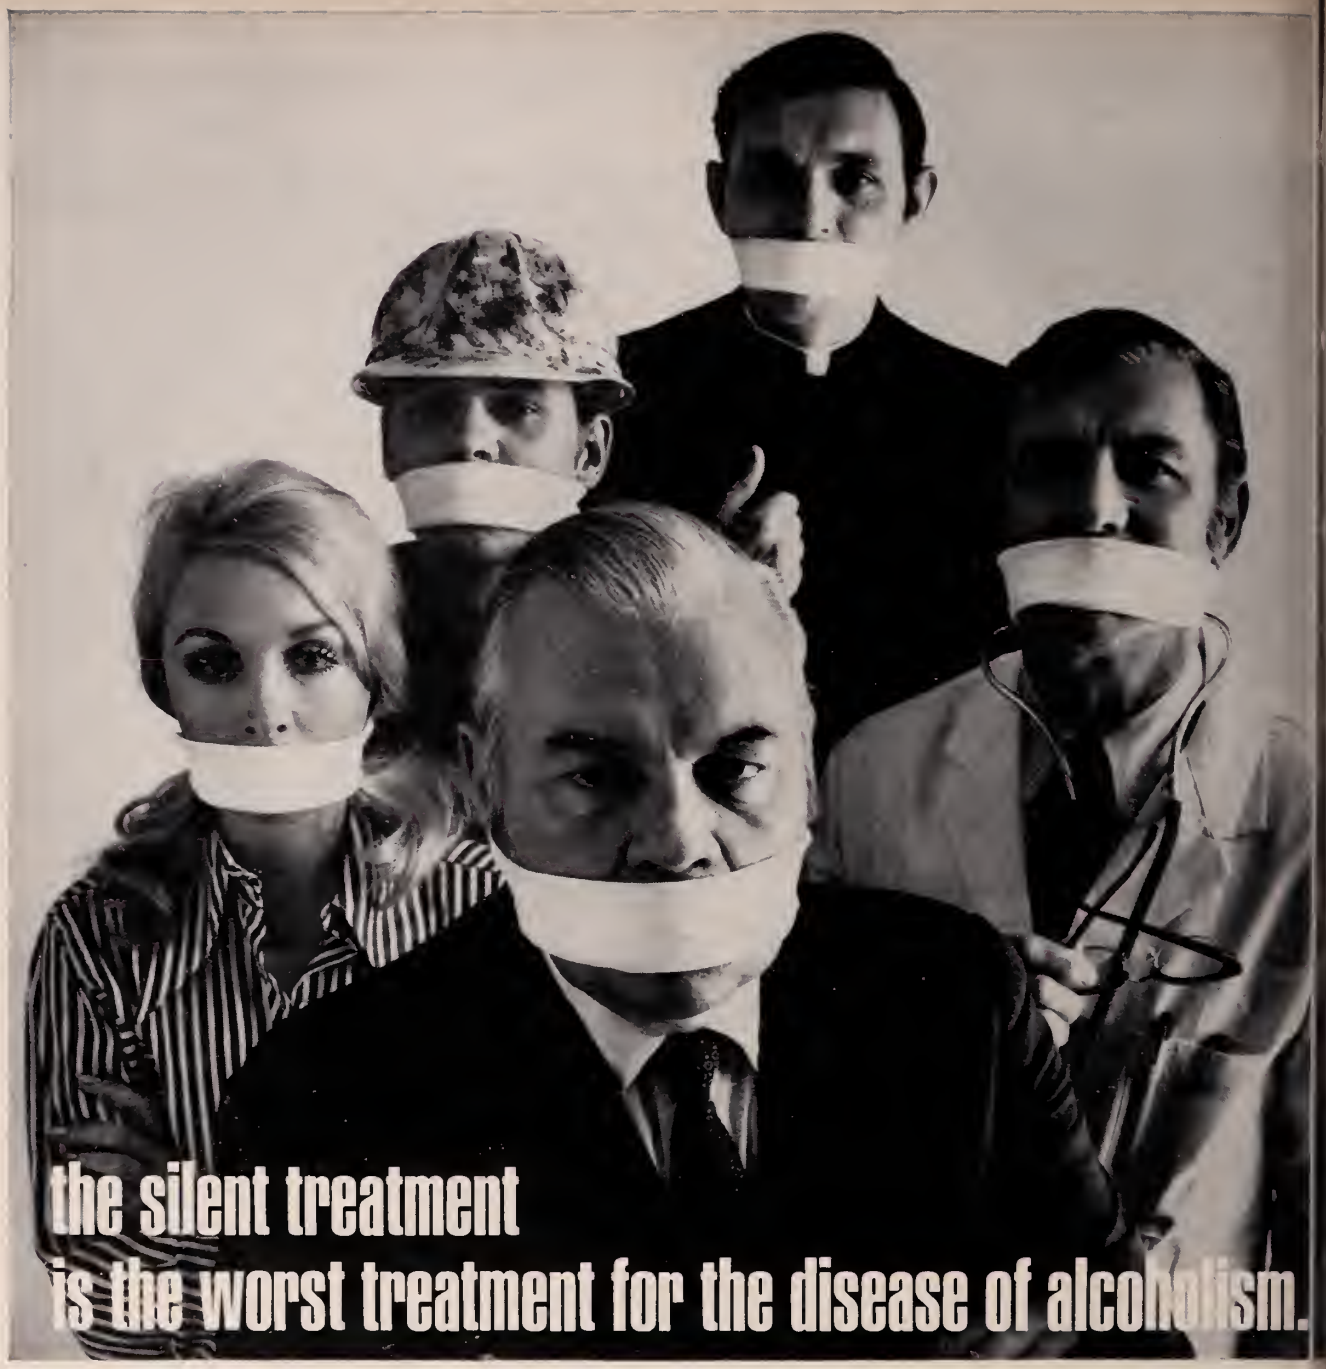
While we have discussed in this paper only a representative sample of the many current activities of the AMA, it should be apparent even to the casual reader, that the physicians of Minnesota need a major national organization to represent them. I believe that physicians want and need a strong effective organization which will carry forward positive programs whose beneficial effects will be realized by all the people in this country.

Medicine today is facing strong forces attempting to direct restructuring of the health delivery and health financing systems with increased controls on physicians and patients alike.

In the next few years, this nation will finally decide whether the patient may choose the physician he will see and whether the physician will provide treatment in accordance with the patient's medical need or in accordance to budgetary or administrative decisions.

The physician body needs a strong representative group more than at any time in history to represent us in these crucial times. Every physician should ask himself this question: "Who would represent him and carry out all the aforementioned activities if there was no AMA?" I submit there is no other organization now able to carry out all of these functions.

It is mandatory that there should always be constructive reassessment of the AMA, but it must be realized there will never be complete agreement on all issues. Minnesota has maintained through the years a high level of AMA membership, but we need more house officers and students to broaden our base of representation.



If you feel the AMA does not represent you, or does not stand for its espoused purposes, "to promote the science and art of medicine and the betterment of public health," you can quietly drop your membership and lose your voice for effective action; or you can complain to others "that blankety blank AMA has goofed again." Your local society and the Minnesota State Medical Association would much rather hear of your opinions and your dissatisfaction. How else can your AMA delegate represent you?

I emphasize it is the responsibility of every physician to voice his opinions and become involved constructively to maintain a strong effective AMA.

George B. Martin, M.D.
AMA Delegate and
President-Elect
Minnesota State Medical Association

Reminder

119th Annual Meeting of the Minnesota State Medical Association in Rochester, Minnesota, May 18, 19 and 20, 1972.

When one out of 20 employees in America—including executives—has alcoholism, it's time for some plain talk about alcoholism. The alcoholic's family, friends and employer may mean well, but the silent treatment is no way to treat a disease. And alcoholism is a disease from which recovery is possible, rather than a moral weakness for which the alcoholic should be pitied—or fired. It's a disease which ranks with heart disease, cancer and severe mental disorders as a public health menace.

The National Council on Alcoholism has pioneered in setting up joint union-management alcoholism programs. In these programs, industry is achieving *recovery rates averaging 60 to 70 percent.* Management profits by retaining its experienced employees and regaining lost productivity—estimated at six billion dollars. Unions profit by increasing health and welfare protection for members and keeping them in the active work force.

If you think alcoholism is affecting your business, **talk it over with the Director of Labor Management Services, National Council on Alcoholism, 2 Park Avenue, New York N.Y. 10016.**

National Council on Alcoholism, Inc.

Book Reviews

THE FUNCTION OF THE MEDICAL OR DENTAL WITNESS IN A PERSONAL INJURY CASE by Robert C. Onan, Jr.

This is a paperback, mimeographed manual dealing with the problems of testimony by the physician or dentist as a witness for either the plaintiff or the defense. It provides a few sample physician's reports which could serve as a guide for the physician who is confronted with the need for providing such a report.

Carl O. Rice, M.D.
Minneapolis, Minnesota

SYNOPSIS OF CLINICAL CANCER, 2nd EDITION by Condict Moore; Publisher: C. V. Mosby Co., St. Louis; Price: $11.75; Pages: About 265; Illustrations: 22.

This book comprises an interesting synopsis on about 25 different organ cancers. The material is well chosen for a basic orientation about cancers in general and for the young clinician it is an excellent point of departure for the study of the most commonly encountered carcinomas.

In each instance it deals basically with the incidence, etiology, pathology, natural history, diagnosis and principles of treatment, deliberately leaving the more extensive and specific details to other sources.

Bibliographic references are adequate and largely current. With the chapter headings and the excellent style of editing, the index proves to be adequate.

Carl O. Rice, M.D.

THE RIGHT TO TREATMENT by Donald S. Burris; Springer Publishing Co., Inc., New York

This is a symposium by about thirteen different authors dealing principally with medical-legal problems: principally those of the socially, economically, and financially underprivileged individuals in relation to their right to treatment in a society that has constantly striven for improvement but has not yet attained perfection. It presents a series of interesting and provocative socio-economic and humanistic problems. Well worth reading!

Carl O. Rice, M.D.
Minneapolis, Minnesota

TUBERCULOSIS by J. Arthur Myers; Warren H. Green, Inc., St. Louis, Missouri; Pages: 353, Price: $8.50.

This well-prepared book is a review of the medical lifetime of one man, beginning at age four, when he had his first awareness of consumption that took the lives of so many people in the years preceding the turn of the century and for a number of years thereafter.

Dr. Myers became progressively more interested in the numerous facets of tuberculosis and has continued to devote his life and energy to the care of, and the eventual conquest of, pulmonary tuberculosis.

The book is a history of the epidemiology of tuberculosis. It gives the experiences of a man and the numerous ramifications of his studies and ever increasing knowledge. He traveled a million miles in this country and abroad, teaching, writing and lecturing on tuberculosis. Without J. Arthur Myers the conquest of tuberculosis could not have attained the success that is now evident in our generation.

Carl O. Rice, M.D.

HOUSE OF A THOUSAND BABIES by Frances W. King-Salmon, M.D.; Pages: 169; Price: $5.00; Exposition Press, New York.

This well written book represents the experiences of an American woman physician in China between the years 1922 and 1940. The young, affable, enthusiastic Frances W. King was one of the co-founders of the Woman's Christian Medical College in Shanghai. Dr. King-Salmon's experiences were thrilling, unique, sometimes horrifying, but always humanized because of her profound interest in people and the society of human beings. Through the Sino-Japanese War in 1937 she saw the collapse of the Chinese dollar. She pointed out the progressively decreasing buying power of a hundred dollar CNC bill, which in 1937 would buy two cows, but which in 1947, under the influence of the rapid takeover of communism would buy only one-third of a pack of matches.

This book should be read by every American because of its sheer fascination. It should be read by all physicians because it has been written from the eyes and the mind of an intellectual physician, and it should be read by all people who have concern for our country, lest we too, in the rat race that we are pursuing, fall victims to an irreversible inflation that no one can afford and without a haven for any one of us to return to.

Dr. Frances W. King-Salmon has portrayed a lifetime of experience that could, in a generation or two, be our own—unless we take heed.

Carl O. Rice, M.D.
Minneapolis, Minnesota

MEDICAL PHYSIOLOGY, by William F. Ganong; Pages: 573; Lange Medical Publications, Los Altos, California 1971.

This is a well constructed paperback volume, covering every practical phase of medical physiology. It is comprised of eight sections which include the major divisions of human physiology within which are incorporated 40 chapters, each dealing with a specific function.

The abbreviations and symbols, which are commonly used in physiology, are defined in the Appendix. The alphabet system, which is being used progressively more often in medical literature, calls for the need of a Medical Abbreviations Dictionary, which in this instance is thoughtfully supplied in the Appendix and without which an uninitiated physician runs into the conundrum of translating the numerous and often unnecessary alphabet abbreviations.

This valuable book is wholeheartedly recommended for every physician who is in the practice of modern medicine.

Carl O. Rice, M.D.
Minneapolis, Minnesota

WANTED NOW: General Practitioner and a Surgeon to join our three-doctor Clinic in Northwest Wisconsin Resort, Forest and Retirement Area Town of 2,400 with a patient population of 25,000. Fully equipped modern Clinic building, with new accredited 50-bed Hospital and 50-bed extended care nursing home. Deer, ducks, partridge and fish 5 minutes away. Generous salary commensurate with training and experience the first year, then full partnership. Brochure with maps and photos upon request. Call collect or write L. J. Olson, M. D., Spooner Clinic Ltd., Spooner, Wisconsin 54801, telephone 715-635-2151.

AVAILABLE—Young married G.P. with some surgical experience. Deferment not needed. Write Minnesota Medicine, 462, 375 Jackson St., St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul 55101.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

GENERAL PRACTITIONER to join young 5 man family practice group. College town of 7,000 serving approximately 20,000 population. Accredited hospital with specialist consulting staff. 30 miles from St. Paul-Minneapolis, Minnesota. Contact R. M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin 54022. Phone (715)-425-5322.

LOCUM TENENS WANTED for July and August, 1972 in Northwest Wisconsin Resort Area Incorporated Practice. Pay $2,000 per month. Will welcome applicant for any other month. Permanent association could result. Send profile to Box 463 Classified Advertisements, c/o Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

GENERAL PRACTITIONER needed by three-man group with downtown and suburban Southdale office. Write MINNESOTA MEDICINE, Box 464, 375 Jackson, St. Paul 55101.

ST. PAUL—Approximately 1200 feet choice medical suite including beautiful lobby and office. Sixteen car parking lot adjoining building. Location 45 Snelling Avenue North, St. Paul, Minnesota, near Macalester College. (612) 645-0271.

EXCELLENT OPPORTUNITY for G.P. or Surgeon in progressive southern Minnesota town of 800. Large rural trade area. Stable economy. Good school system. 18 hole golf course and clubhouse, swimming pool, parks and playgrounds. Near Rochester and Austin. Building and equipment available for purchase or rent. Inquire Farmers State Bank of Adams, Minn., telephone 507-582-3448.

GENERAL PRACTITIONER to join 2 man group, family practice. Busy, well established location in town of 2000 with drawing area 10,000. Excellent schools, churches, golf club, hunting and fishing, 65 miles from Twin Cities. Completely equipped and staffed clinic. New 40-bed hospital, accredited. Salary arrangements to start and early partnership. Write MINNESOTA MEDICINE, Box 465, 375 Jackson St., St. Paul 55101.

STUDENT HEALTH SERVICE—Full time staff position available immediately at Mankato State College, Mankato, Minn. Salary $25,000 1 month vacation plus holidays and other fringe benefits. Dr. Harry Brauer M.D., Student Health Service, Mankato, Minn. 56001. 507-389 2726.

FOR LEASE—Ideal Doctor's office space. Lane Park Professional Center, centrally located in Brooklyn Park. 3 story brick building, 350-20,000 sq. ft. available, thermostatically controlled heat and air conditioning, elevator, carpeting, ample parking. Lease to your specification. Space available mid summer 1972. ¾ mile from Freeway 694, within walking distance to two shopping centers. For leasing information call Don Mannstedt 561-6362.

WANTED: General practitioner wanted to join a young four man group in a fast growing area just 30 minutes south of the Twin Cities. You will practice in a new clinic, hospital and nursing home. A compete resume of facilities, practice and area is available. Contact M. H. Hunter, M.D.: Rivers-Edge Medical Clinic, Farmington, Minnesota. Telephone 463-7181.

T_4 IS THE PREDICTABLE HORMONE BECAUSE IT LOVES PROTEIN.

SYNTHROID® (sodium levothyroxine) is pure synthetic T_4, the major circulating thyroid hormone. It is reliable to use because of its affinity for protein-binding sites in the blood. T_3 is more fickle. Sometimes it binds. Sometimes it doesn't. T_4 more *predictably* binds to protein.

Synthroid®
(sodium levothyroxine)

ALL THYROID-FUNCTION TESTS ARE USEFUL IN MONITORING SYNTHROID THERAPY.

No calculations are needed, test interpretation is simple.

Any of the commonly used T_4 thyroid function tests (P.B.I., T_4 By Column, Murphy-Pattee, Free Thyroxine) are useful in monitoring patients on T_4 because they *all* measure T_4. Patients on SYNTHROID are thereby easy to monitor because their results will fall within predictable, elevated test ranges. Of course, clinical assessment is the best criterion of the thyroid status of the drug-treated patient.

TWO GOOD REASONS WHY THE ROAD TO NORMALIZED THYROID STATUS IS SO SMOOTH FOR THE SYNTHROID PATIENT.

(1) The onset of action of T_4 is gradual. It has a long in vivo "half-life" of over six days. (Occasional missed doses or accidental double-doses are of less concern because of this factor)[1]; (2) since SYNTHROID contains only T_4, the potential for metabolic surges traceable to more potent iodides (T_3) is eliminated.

1. Latiolais, C. J., and Berry, C. C.: Misuse of Prescription Medications by Outpatients, *Drug Intelligence & Clin. Pharm.* 3:270-7, 1969

TEST	HYPOTHYROID	SYNTHROID THERAPEUTIC NORMAL
P.B.I.	Less than 4 mcg %	6-10 mcg %
T_4 By Column	Less than 3 mcg %	7-9 mcg %
T_3 (Resin)	Less than 25%	27-35%
T_3 (Red Cell)	Less than 11%	11.5-18%
Free Thyroxine	Less than 0.7 nanograms %	0.7-2.5 nanograms %
Murphy-Pattee	Less than 2.9 mcg %	4-11 mcg %

Choose the Smooth Road ...to thyroid replacement therapy

HY DOES SYNTHROID ST LESS THAN NTHETIC DRUGS NTAINING T_3?

y simple. T_3 costs more to make thetically than does T_4. So it is nomically necessary for a thetic thyroid medication taining T_3 to cost more than containing T_4 alone. Synthetic binations cost patients nearly % more than SYNTHROID[3] ause the T_3 costs more to start ; also there is the additional ense of formulating a tablet taining two active ingredients.

nericen Druggist BLUEBOOK, March, 1971.

KNOWLEDGE OF THE '70's CHALLENGES CUSTOMS CONCERNING DESICCATED THYROID DRUGS.

In the past, desiccated thyroid produced from animal glands was considered "good, and cheap." We now know that improved products are available and the price difference has narrowed to the point of being inconsequential. (SYNTHROID, for instance, costs patients about a penny a day more than brands of desiccated thyroid.)

What does this additional $3.65 a year buy the patient? Quite a bit in terms of quality, reliability and service.

SWITCHING PATIENTS TO SYNTHROID IS EASY.

Switching present patients to SYNTHROID (or starting new ones) is a simple matter. SYNTHROID is available in the widest range of dosage strengths of any thyroid drug. Seven scored, color-coded tablet strengths are available plus a lyophilized injectable form for emergency or postoperative uses.

RESPONSE, RELIABILITY, SERVICE—COMPARISON OF FIVE PARAMETERS

ARAMETERS	DESICCATED THYROID U.S.P.	SYNTHROID® (sodium levothyroxine)
OURCE OF HORMONE	Animal glands (swine, sheep, cows). Hormone content of glends end retio of T_3-T_4 veries by type of enimal, season in which gland is hervested, and diet of enimal.[1,2,3,4,5]	Synthetically derived pure crystelline hormone. Because no animal protein is present, no objectioneble odor occurs upon aging.
ENERAL ASSAY TECHNIQUE	"Its major disadvantage is inadequate standardization of hormonel content."[8]	Unlike desiccated thyroid U.S.P., thyroxine does not require biologic standardizetion to establish its potency.[2,6] Crystelline T_4 is used. Purity is verified by peper chrometography. Content of teblets is standardized by weight.
LINICAL RESPONSE	"T_3 and T_4 ratio veries eccording to glend source. Fluctuations in response can occur. Potency cen vary."[3]	"Sodium levothyroxine has been extensively used with satisfaction end is widely held to be superior to (desiccated) thyroid."[7] "There ere well documented exemples of petients who felled to respond satisfactorily to desicceted thyroid but subsequently responded to (sodium-1) thyroxine."[4]
REDICTABILITY	Failure of thyroid U.S.P. treated patients to show clinical improvement and/or lack of correlation in clinical findings to thyroid function test results has been frequently discussed in the literature.[8,9,10,11,12,13,14,15,16] Regardless of which fector or fectors accounts for this phenomenon the fect remains thet discrepancies do occur.	Test results predictebly eleveted. ". . . orel potency of this materiel is attested to by e uniformly good clinical response corroboreted by e prompt end sustained increese in the serum PBI levels."[16]

See next pages for prescribing information.

PATIENTS CAN BE SUCCESSFULLY MAINTAINED ON A DRUG CONTAINING THYROXINE ALONE.

Thyroxine (T_4) is, as you know, the major circulating hormone produced by the thyroid gland. T_3 is also produced, in smaller amounts, and is active at the cellular level. For years it has been a working hypothesis among endocrinologists that T_4 is converted by the body to T_3. In 1970 this process, called "deiodination," was demonstrated by Braverman, Ingbar, and Sterling[2]. T_4 does convert to T_3, though the precise quantities are still being studied.

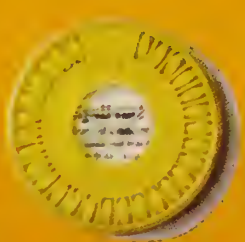
The conversion has been clinically demonstrated during the administration of T_4 to athyrotic patients. Their thyroid status is normalized on SYNTHROID alone, yet the presence of T_3 in these patients has been clearly shown.

CONSIDERATE LONG-TERM THERAPY FOR THE PATIENT.

Predictable patient response, of course, is more important than price. You do get complete clinical response with the single-entity synthetic, SYNTHROID. And, at a reasonable cost to the patient. In some short term situations, T_3 drugs can be useful but, in long term therapy, the smooth road provided by SYNTHROID may be the better route.

SYNTHROID, with its smooth road to complete thyroid replacement therapy, has been selected for more patients in the United States and Canada than any other brand of thyroid medication.

2. Braverman, L. E., Ingbar, S. H., and Sterling, K.: Conversion of Thyroxine (T4) to Triiodothyronine (T3) in Athyreotic Human Subjects, *J. Clin. Invest.* 49:855-64, 1970.



AS WITH ANY THYROID PREPARATION, CAUTIOUS OBSERVATION OF TH PATIENT DURING TH BEGINNING OF THERAPY WILL ALER THE PHYSICIAN TO ANY UNTOWARD EFFECTS.

Side effects, when they do occ are related to excessive dosage Caution should be exercised ir administering the drug to patier with cardiovascular disease. Re the accompanying prescribing information for additional data write Flint Laboratories.

*Equivalents shown are chemical, and do not take into consideration individual patient variables. Clinical effect is approximate and should be monitored when converting a patient to SYNTHROID. This is particularly important in patients previcusly on desiccated thyroid. In these patients, lower doses of SYNTHROID may produce the same metabolic effect.

**Euthrold (#1 tablet) contains 60 mcg. of T_4 and 15 mcg. of T_3.

**Thyrolar (#1 tablet) contains 50 mcg. of T_4 and 12.5 mcg. of T_3.

Synthroid®
(sodium levothyroxine)

Indications: SYNTHROID (sodium levothyroxine) is specific replacement therapy for diminished or absent thyroid function resulting from primary or secondary atrophy of the gland, congenital defect, surgery, excessive radiation, or antithyroid drugs. Indications for SYNTHROID (sodium levothyroxine) **Tablets** include myxedema, hypothyroidism without myxedema, hypothyroidism in pregnancy, pediatric and geriatric hypothyroidism, hypopituitary hypothyroidism, simple (nontoxic) goiter, and reproductive disorders associated with hypothyroidism. SYNTHROID (sodium levothyroxine) for **Injection** is indicated for intravenous use in myxedematous coma and other thyroid dysfunctions where rapid replacement of the hormone is required. The injection is also indicated for intramuscular use in cases where the oral route is suspect or contraindicated due to existing conditions or to absorption defects, and when a rapid onset of effect is not desired.

Precautions: As with other thyroid preparations, an overdosage may cause diarrhea or cramps, nervousness, tremors, tachycardia, vomiting and continued weight loss. These effects may begin after four or five days or may not become apparent for one to three weeks. Patients receiving the drug should be observed closely for signs of thyrotoxicosis. If indications of overdosage appear, discontinue medication for 2-6 days, then resume at a lower dosage level. In patients with diabetes mellitus, careful observations should be made for changes in insulin or other antidiabetic drug dosage requirements. If hypothyroidism is accompanied by adrenal insufficiency, as Addison's Disease (chronic subcortical insufficiency), Simmonds's Disease (panhypopituitarism) or Cushing's syndrome (hyperadrenalism), these dysfunctions must be corrected prior to and during SYNTHROID (sodium levothyroxine) administration. The drug should be administered with caution to patients with cardiovascular disease; development of chest pains or other aggravations of cardiovascular disease requires a reduction in dosage.

Contraindications: Thyrotoxicosis, acute myocardial infarction. **Side effects:** The effects of SYNTHROID (sodium levothyroxine) therapy are slow in being manifested. Side effects, when they do occur, are secondary to increased rates of body metabolism; sweating, heart palpitations with or without pain, leg cramps, and weight loss. Diarrhea, vomiting, and nervousness have also been observed. Myxedematous patients with heart disease have died from abrupt increases in dosage of thyroid drugs. Careful observation of the patient during the beginning of any thyroid therapy will alert the physician to any untoward effects.

In most cases with side effects, a reduction of dosage followed by a more gradual adjustment upward will result in a more accurate indication of the patient's dosage requirements without the appearance of side effects.

Dosage and Administration: The activity of a 0.1 mg. SYNTHROID (sodium levothyroxine) **TABLET** is equivalent to approximately one grain thyroid, U.S.P. Administer SYNTHROID tablets as a single daily dose, preferably after breakfast. In hypothyroidism without myxedema, the usual initial adult dose is 0.1 mg. daily, and may be increased by 0.1 mg. every 30 days until proper metabolic balance is attained. Clinical evaluation should be made monthly and PBI measurements about every 90 days. Final maintenance dosage will usually range from 0.2-0.4 mg. daily. In adult myxedema, starting dose should be 0.025 mg. daily. The dose may be increased to 0.05 mg. after two weeks and to 0.1 mg. at the end of a second two weeks. The daily dose may be further increased at two-month intervals by 0.1 mg. until the optimum maintenance dose is reached (0.1-1.0 mg. daily).

Supplied: Tablets: 0.025 mg., 0.05 mg., 0.1 mg., 0.15 mg., 0.2 mg., 0.3 mg., 0.5 mg., scored and color-coded, in bottles of 100, 500, and 1000. Injection: 500 mcg. lyophilized active ingredient and 10 mg. of Mannitol, N.F., in 10 ml. single-dose vial, with 5 ml. vial of Sodium Chloride Injection, U.S.P., as a diluent. SYNTHROID (sodium levothyroxine) for **Injection** may be administered intravenously utilizing 200-400 mcg. of a solution containing 100 mcg. per ml. If significant improvement is not shown the following day, a repeat injection of 100-200 mcg. may be given.

THE FACTS ARE CLEAR AND HERE IS OUR OFFER.

Synthetic thyroid drugs are an improvement over animal gland products. Patients, even athyrotic ones, can be completely maintained on SYNTHROID (T_4) alone. Thyroid function tests are easy to interpret since they are *predictably* elevated when the patient adheres to SYNTHROID. Of all synthetic thyroid drugs, SYNTHROID is the most economical to the patient.

OFFER: AA

Free TAB-MINDER medication dispensers to start or convert all your hypothyroid patients to SYNTHROID. Free information to physicians on role of thyroid function tests in a new booklet titled: "Guideposts to Thyroid Therapy." Ask us.

optional therapy

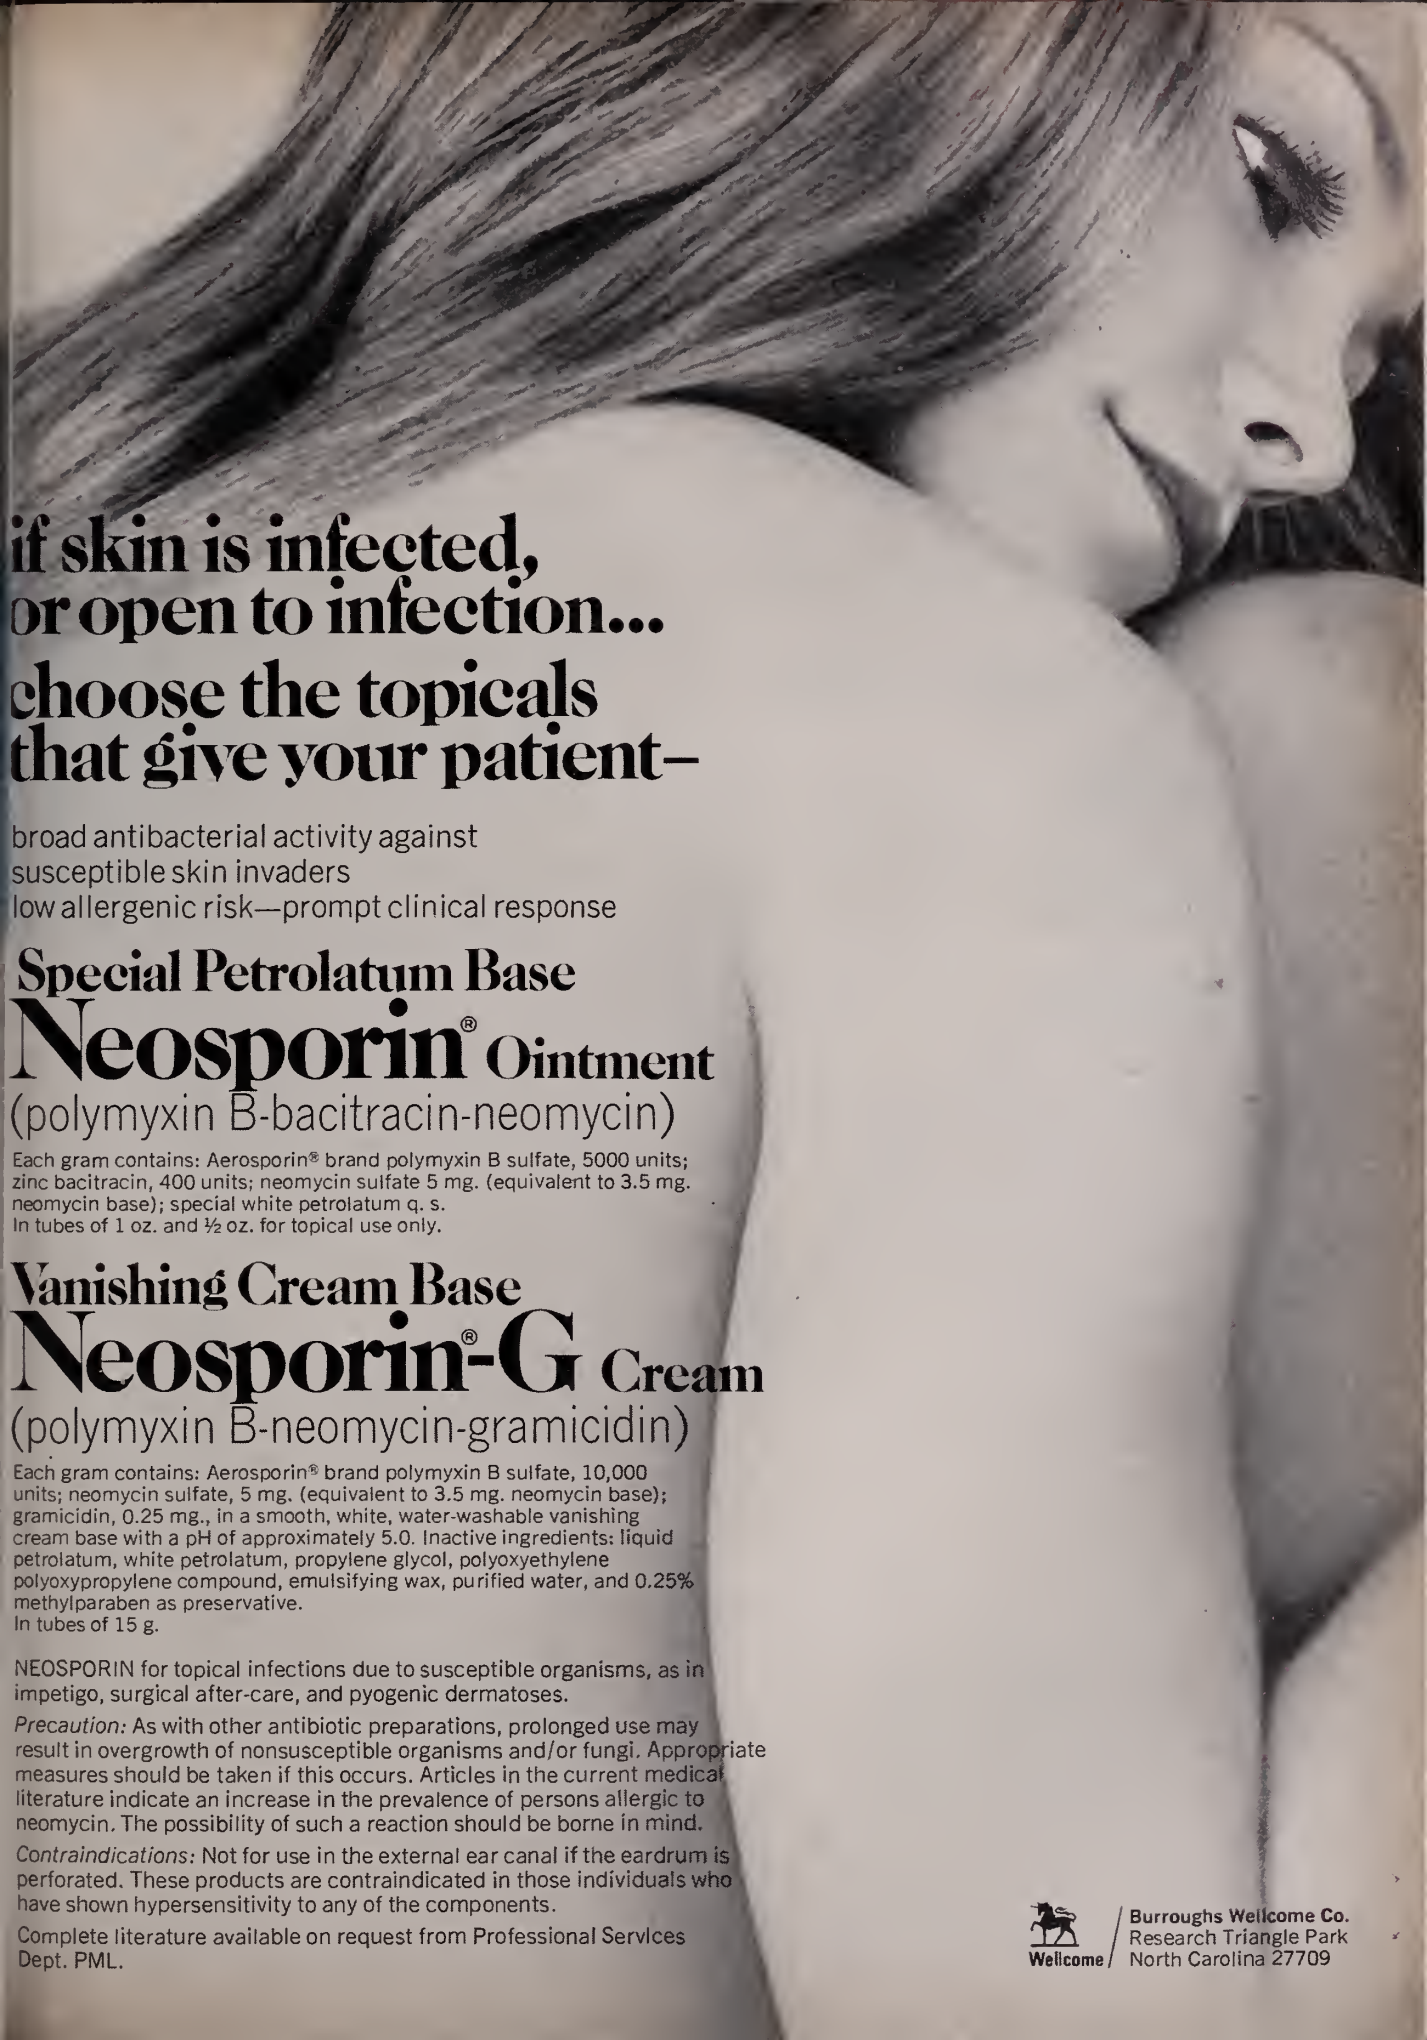
THE mudranes®

All Mudranes are bronchodilator-mucolytic in action, and are indicated for symptomatic relief of bronchial asthma, emphysema, bronchiectasis and chronic bronchitis. **MUDRANE tablets** contain 195 mg. potassium iodide; 130 mg. aminophylline; 21 mg. phenobarbital (Warning: may be habit-forming); 16 mg. ephedrine HCl. **Dosage** is one tablet with full glass of water, 3 or 4 times a day. **Precautions** are those for aminophylline-phenobarbital-ephedrine combinations. **Iodide side-effects:** May cause nausea. Very long use may cause goiter. Discontinue if symptoms of iodism develop. **Iodide contraindications:** Tuberculosis; pregnancy (to protect the fetus against possible depression of thyroid activity). **MUDRANE-2 tablets** contain 195 mg. potassium iodide; 130 mg. aminophylline. **Dosage** is one tablet with full glass of water, 3 or 4 times a day. **Precautions** are those for aminophylline. **Iodide side-effects and contraindications are listed above. MUDRANE GG tablets** contain 100 mg. glyceryl guaiacolate; 130 mg. aminophylline; 21 mg. phenobarbital (Warning: may be habit-forming); 16 mg. ephedrine HCl. **Dosage** is one tablet with full glass of water, 3 or 4 times a day. **Precautions** are those for aminophylline-phenobarbital-ephedrine combinations. **MUDRANE GG-2 tablets** contain 100 mg. glyceryl guaiacolate; 130 mg. aminophylline. **Dosage** is one tablet with full glass of water, 3 or 4 times a day. **Precautions:** Those for aminophylline. **MUDRANE GG Elixir.** Each teaspoonful (5 cc) contains 26 mg. glyceryl guaiacolate; 20 mg. theophylline; 5.4 mg. phenobarbital (Warning: may be habit-forming); 4 mg. ephedrine HCl. **Dosage:** Children, 1 cc for each 10 lbs. of body weight; one teaspoonful (5 cc) for a 50 lb. child. Dose may be repeated 3 or 4 times a day. Adult, one tablespoonful, 4 times daily. All doses should be followed with ½ to full glass of water. **Precautions:** See those listed above for Mudrane GG tablets.

MUDRANE—original formula
First choice

MUDRANE-2
When ephedrine is too exciting or is contraindicated

MUDRANE GG
During pregnancy or when K.I. is contraindicated or not tolerated



MUDRANE GG-2
A counterpart for Mudrane-2

MUDRANE GG ELIXIR
For pediatric use or where liquids are preferred

Clinical specimens available to physicians.

Manufacturers of Ethical Pharmaceuticals

if skin is infected, or open to infection...

choose the topicals that give your patient–

broad antibacterial activity against
susceptible skin invaders
low allergenic risk—prompt clinical response

Special Petrolatum Base
Neosporin® Ointment
(polymyxin B-bacitracin-neomycin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 5000 units; zinc bacitracin, 400 units; neomycin sulfate 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q. s.
In tubes of 1 oz. and ½ oz. for topical use only.

Vanishing Cream Base
Neosporin®-G Cream
(polymyxin B-neomycin-gramicidin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 10,000 units; neomycin sulfate, 5 mg. (equivalent to 3.5 mg. neomycin base); gramicidin, 0.25 mg., in a smooth, white, water-washable vanishing cream base with a pH of approximately 5.0. Inactive ingredients: liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax, purified water, and 0.25% methylparaben as preservative.
In tubes of 15 g.

NEOSPORIN for topical infections due to susceptible organisms, as in impetigo, surgical after-care, and pyogenic dermatoses.

Precaution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: Not for use in the external ear canal if the eardrum is perforated. These products are contraindicated in those individuals who have shown hypersensitivity to any of the components.

Complete literature available on request from Professional Services Dept. PML.

rheumatoid arthritic blowup...

Tandearil® Geigy

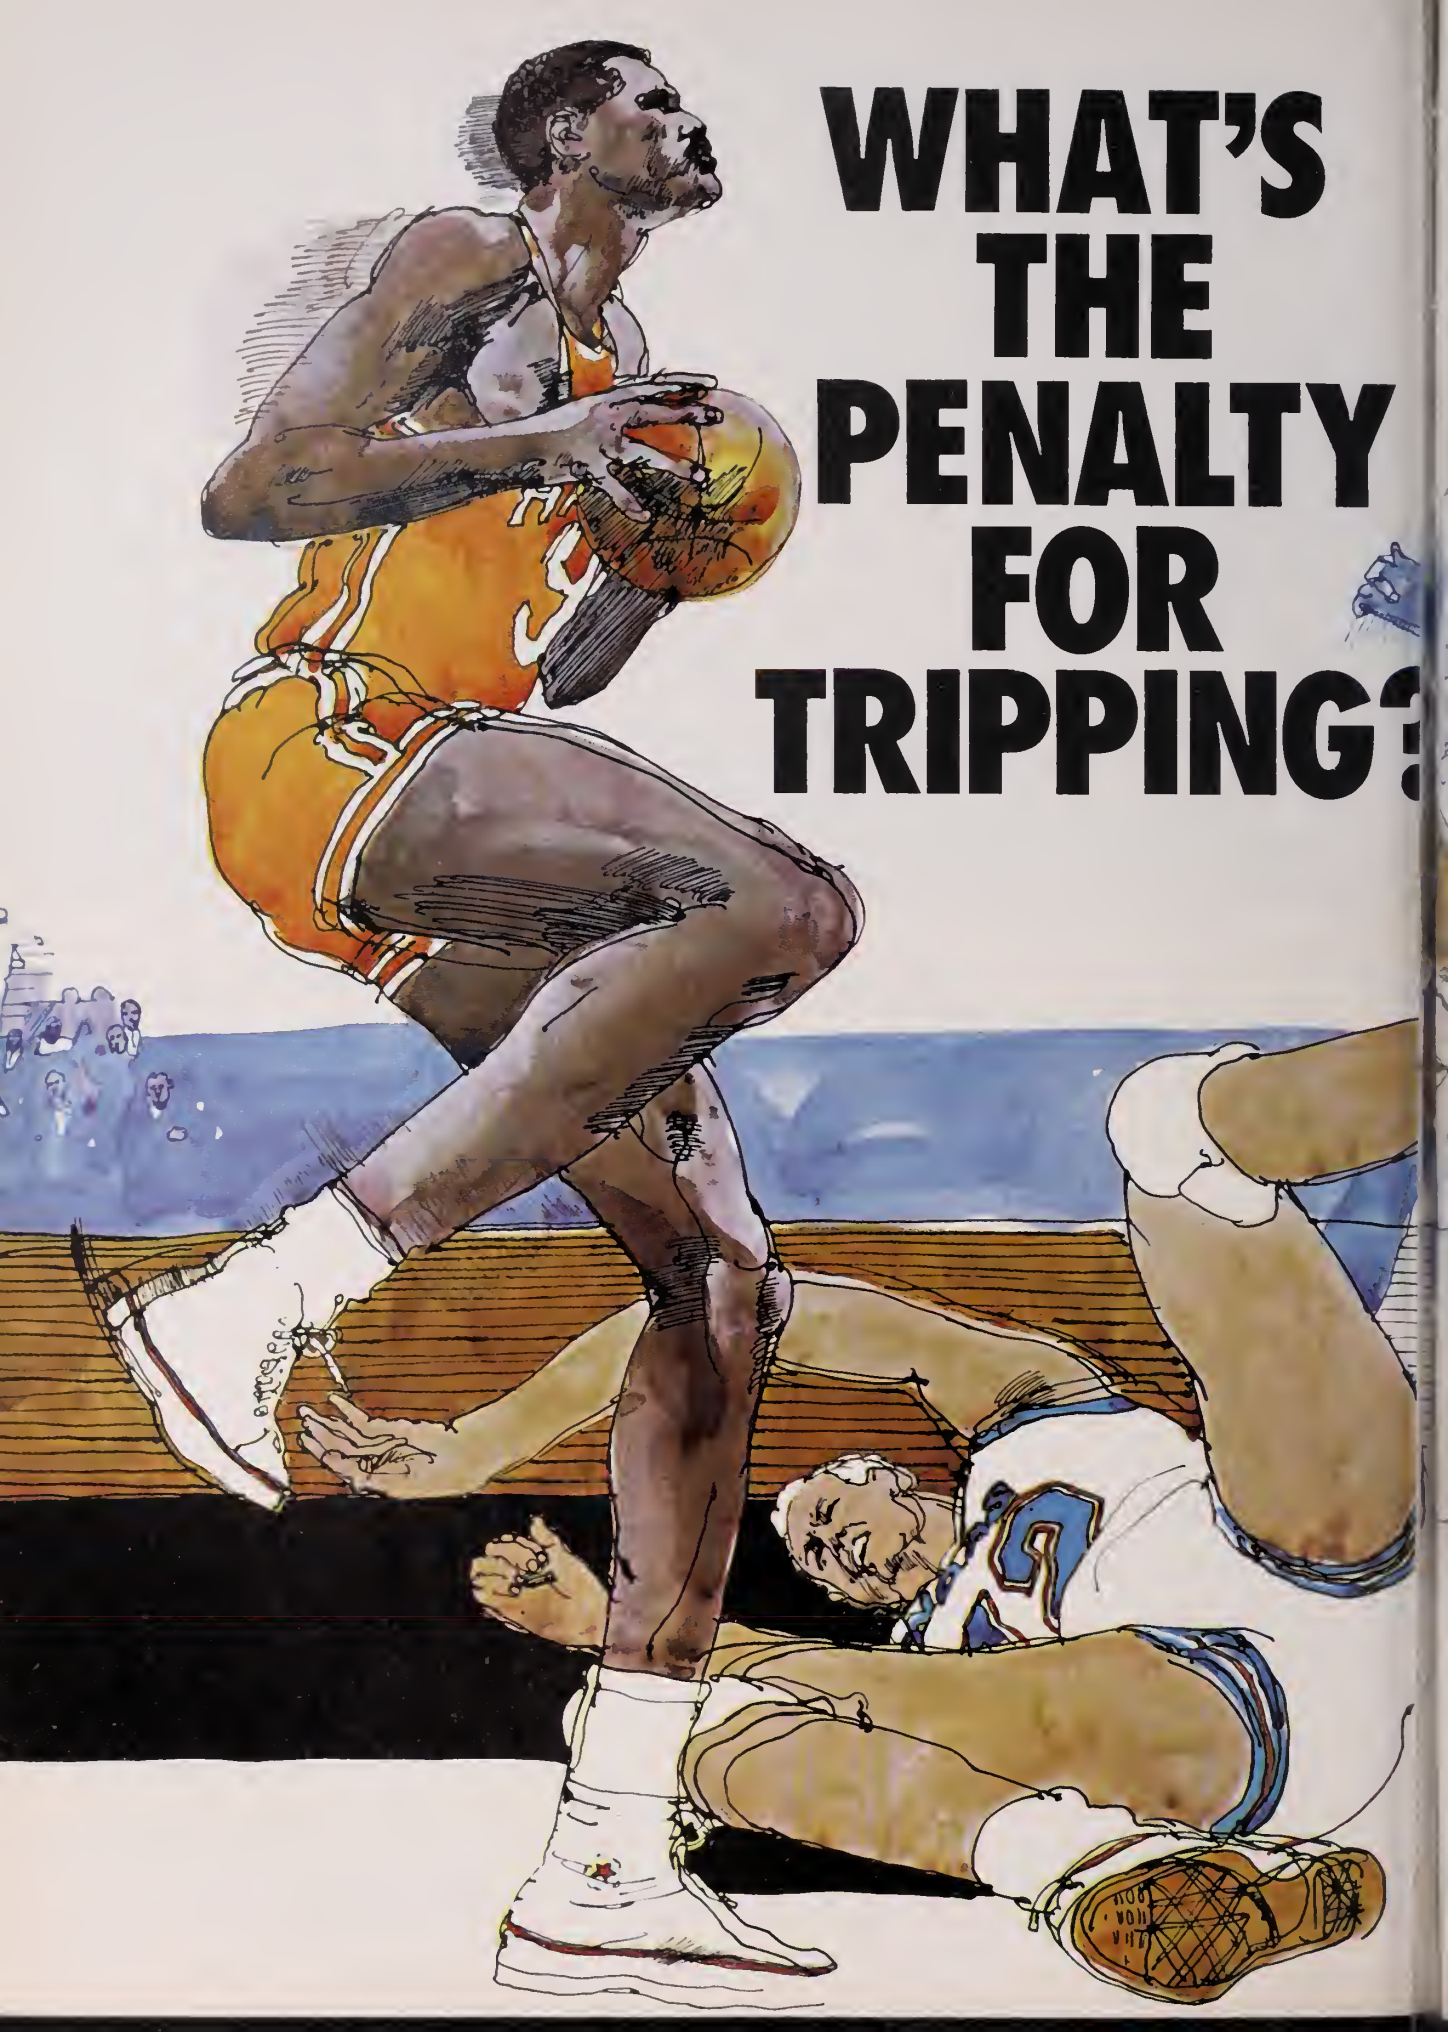
oxyphenbutazone NF tablets of 100 mg.

nportant Note: This drug is not a simple analgesic. o not administer casually. Carefully evaluate patients efore starting treatment and keep them under close pervision. Obtain a detailed history, and complete ysical and laboratory examination (complete emogram, urinalysis, etc.) before prescribing and at equent intervals thereafter. Carefully select patients, voiding those responsive to routine measures, con-aindicated patients or those who cannot be observed equently. Warn patients not to exceed recommended osage. Short-term relief of severe symptoms with e smallest possible dosage is the goal of therapy. osage should be taken with meals or a full glass of ilk. Patients should discontinue the drug and report mediately any sign of: fever, sore throat, oral sions (symptoms of blood dyscrasia); dyspepsia, pigastric pain, symptoms of anemia, black or tarry ools or other evidence of intestinal ulceration or emorrhage, skin reactions, significant weight gain or dema. A one-week trial period is adequate. Discon-nue in the absence of a favorable response. Restrict eatment periods to one week in patients over sixty. *dications:* Acute gouty arthritis, rheumatoid arthritis, eumatoid spondylitis.

ontraindications: Children 14 years or less; senile atients; history or symptoms of G.I. inflammation or ceration including severe, recurrent or persistent yspepsia; history or presence of drug allergy; blood yscrasias; renal, hepatic or cardiac dysfunction; pertension; thyroid disease; systemic edema; omatitis and salivary gland enlargement due to the rug; polymyalgia rheumatica and temporal arteritis; atients receiving other potent chemotherapeutic gents, or long-term anticoagulant therapy.

arnings: Age, weight, dosage, duration of therapy, xistence of concomitant diseases, and concurrent otent chemotherapy affect incidence of toxic reac-ons. Carefully instruct and observe the individual atient, especially the aging (forty years and over) ho have increased susceptibility to the toxicity of the rug. Use lowest effective dosage. Weigh initially npredictable benefits against potential risk of severe, ven fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type peins can be the presenting symptom of leukemia.



Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute end reactivated gastric and duodenal ulcer with perforation end hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia, gastritis, epigastric pain, hematemesis, dyspepsie, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angiitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter association of hyperthyroidism and hypothyroidism (ceusal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, Including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement.

GEIGY Pharmaceuticals
Division of CIBA-GEIGY Corporation
Ardsley, New York 10502

TA. 8356-9

WHAT'S
THE
PENALTY
FOR
TRIPPING?

A personal foul against the tripper, and possibly weeks of painful skeletal muscle spasm for the victim.

For the skeletal muscle spasm of leg strains, Valium® (diazepam) can be a valuable adjunct. A dose of 2-10 mg, three or four times a day, goes to work to help break up the cycle of spasm/pain/spasm. The resultant relief of skeletal muscle spasm may permit greater mobilization of the affected muscles and may help the patient resume usual activities sooner than otherwise possible.

Sudden trauma to and unusual stress on sartorius muscle may cause strain of muscle and tearing of some of the fibers. The resultant muscle spasm can make leg motion painful.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Roche Laboratories
Division of Hoffmann-La Roche Inc
Nutley, N J 07110

VALIUM® (diazepam)

adjunct in skeletal muscle spasm

2-mg, 5-mg, 10-mg tablets

To get the water out in edema*

To lower blood pressure in hypertension*

To spare potassium in both

There's

Dyazide®

Trademark

Each capsule contains 50 mg. of Dyrenium® (brand of triamterene) and 25 mg. of hydrochlorothiazide.

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

***Indications:** Edema associated with congestive heart failure, cirrhosis of the liver, the nephrotic syndrome, late pregnancy; also steroid-induced and idiopathic edema, and edema resistant to other diuretic therapy. 'Dyazide' is also indicated in the treatment of mild to moderate hypertension.

Contraindications: Pre-existing elevated serum potassium. Hypersensitivity to either component. Continued use in progressive renal or hepatic dysfunction or developing hyperkalemia.

Warnings: Do not use dietary potassium supplements or potassium salts unless hypokalemia develops or dietary potassium intake is markedly impaired. Enteric-coated potassium salts may cause small bowel stenosis with or without ulceration. Hyperkalemia (>5.4 mEq/L) has been reported in 4% of patients under 60 years, in 12% of patients over 60 years, and in less than 8% of patients overall. Rarely, cases have been associated with cardiac irregularities. Accordingly, **check serum potassium during therapy, particularly in patients with suspected or confirmed renal insufficiency (e.g., certain elderly or diabetics). If hyperkalemia develops, substitute a thiazide alone. If spironolactone is used concomitantly with 'Dyazide', check serum potassium frequently**--they can both cause potassium retention and sometimes hyperkalemia. Two deaths have been reported in patients on such combined therapy (in one, recommended dosage was exceeded; in the other, serum electrolytes were not properly monitored). Observe regularly for possible blood dyscrasias, liver damage or other idiosyncratic reactions. Blood dyscrasias have been reported in patients receiving Dyrenium (triamterene, SK&F). Rarely, leukopenia, thrombocytopenia, agranulocytosis, and aplastic anemia have been reported with the thiazides. Watch for signs of impending coma in acutely ill cirrhotics. Thiazides are reported to cross the placental barrier and appear in breast milk. This may result in fetal or neonatal hyperbilirubinemia, thrombocytopenia, altered carbohydrate metabolism and possibly other adverse reactions that have occurred in the adult. When used during pregnancy or in women who might bear children, weigh potential benefits against possible hazards to fetus.

Precautions: Do periodic serum electrolyte and BUN determinations. Do periodic hematologic studies in cirrhotics with splenomegaly. Antihypertensive effects may be enhanced in postsympathectomy patients. The following may occur: hyperuricemia and gout, reversible nitrogen retention, decreasing alkali reserve with possible metabolic acidosis, hyperglycemia and glycosuria (diabetic insulin requirements may be altered), digitalis intoxication (in hypokalemia). Use cautiously in surgical patients. Concomitant use with antihypertensive agents may result in an additive hypotensive effect.

Adverse Reactions: Muscle cramps, weakness, dizziness, headache, dry mouth; anaphylaxis; rash, urticaria, photosensitivity, purpura, other dermatological conditions; nausea and vomiting (may indicate electrolyte imbalance), diarrhea, constipation, other gastrointestinal disturbances. Rarely, necrotizing vasculitis, paresthesias, icterus, pancreatitis, and xanthopsia have occurred with thiazides alone.

Supplied: Bottles of 100 capsules.

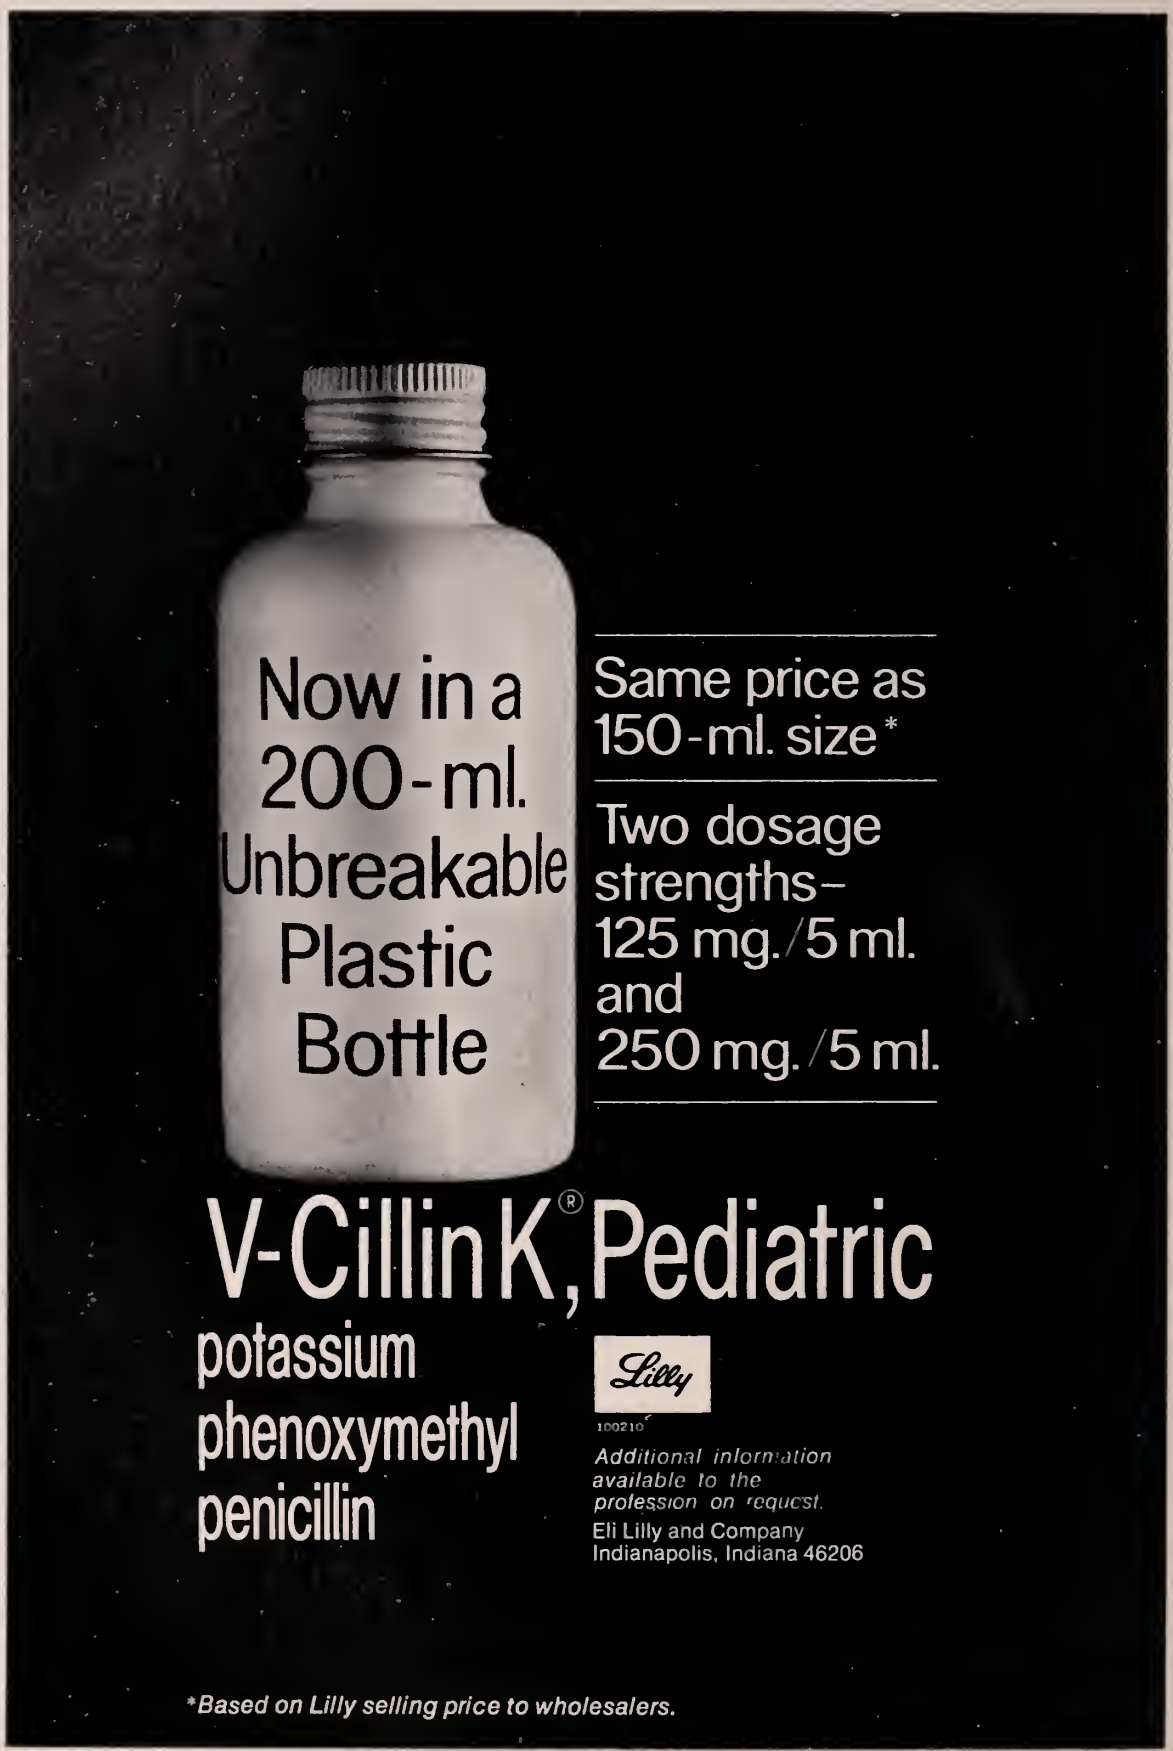
President's Letter

Annual Meeting

MANY CHANGES are being made to make our Annual Meeting of the Minnesota State Medical Association more attractive to the members. The dates for our meeting are May 18, 19 and 20, and it will take place on Thursday, Friday and Saturday, with Saturday A.M. being reserved for our specialty societies. We hope that in the future, many of our specialty societies will be able to hold their annual meetings in conjunction with the State Association Annual Meeting.

By holding the Annual Meeting at the end of the week, we hope that many busy physicians will find this more convenient, and we are not competing with the opening weekend of fishing season. I am sure that many of our physician-fishermen will be pleased to know that they can open the fishing season properly and also attend our annual meeting.

The Committee on Scientific Assembly has done a terrific job in providing an interesting program with an excellent group of speakers. I want to thank Doctor John Mayne, Chairman of this Committee, for doing such an efficient job. The variety of program subjects is unsurpassed. The speakers will make brief, informative presentations. No presentation will be more than 15 or 20 minutes. This enables more subjects to be covered. With the variety of subjects being presented, I can assure that all physicians in Minnesota will find topics in their special interests. The afternoons of Thursday and Friday will be devoted to panel discussions of general subjects.



I would like to take this opportunity to invite all members of the Minnesota State Medical Association and their wives to attend the President's Reception at 6 P.M. on Thursday evening and the Annual Banquet at 7:00 P.M. Donna and I would like to meet as many of you as possible. There will be excellent entertainment during the banquet and dancing to follow the banquet. The Women's Auxiliary has also planned an active program so there will be a great deal of activity for the physician's wife.

The Annual Meeting is the most important function of our Minnesota State Medical Association. Good attendance is a symbol of the strength of the Association.

With these many changes that are being initiated, I hope that every one of our members and their wives will want to attend the Annual Meeting of the Minnesota State Medical Association.

The Arthritic Hip*

Current Concepts of Surgical Management

DAVID S. BRADFORD, M.D.†

RECONSTRUCTIVE SURGERY of the hip has undergone great advances in the past decade. Improvement in techniques and prosthetic implants has furnished a means of reconstructing arthritic hips previously felt unsalvageable. The family physician has assumed an increasingly important role in the management of patients with painful hip disease. It is desirable, therefore, that he have an adequate understanding of operative indications and treatment. This manuscript is presented as a review of the pathology of degenerative and rheumatoid arthritis involving the hip, the clinical manifestations, and the current concepts of surgical management.

Pathology[14,18,19]

The intelligent planning and execution of surgery is dependent on recognition of the pathology initiating the arthritic process. By far the most common type of arthritis affecting the hip joint is osteoarthritis or degenerative arthritis. The pathology is characterized by cartilage fibrillation, osteophytes, and subchondral bone formation. Microscopically, the cartilage will demonstrate surface irregularities with fissures running parallel to the collagen fibers. Chondrocytes may be clumped at the base of the fissures suggesting attempts at repair. Special stains will show a loss in metachromasia secondary to a decrease in acidic glycosaminoglycans. X-ray examination of the hip may show narrowing of the joint space secondary to the loss of surface cartilage. Similarly cyst formation and sclerosis immediately below the joint surface and osteophytes at the margin of the cartilage or at points of ligament and capsular attachments may be identified. Primary osteoarthritis occurs de novo without known predisposing factors. Secondary osteoarthritis develops from alternations in the normal joint structure slipped epiphysis, hip dysplasia, (Perthes' disease), in association with metabolic disease (ochronosis, spondyloepiphyseal dysphasia, acromegaly), or following trauma, infection, or avascular neucrosis.

Rheumatoid arthritis on the other hand begins basically as an inflammation of the synovium. The pathologic synovial tissue, although non-specific histologically, demonstrates edema, congestion, fibrin exudation, and cellular infiltration. As the synovium becomes thickened it is thrown into folds or villi, spreading over the cartilage surface as a pannus eroding the cartilage as well as subchondral bone. Periarticular tissues may likewise become involved. This may lead to contractures of capsule, ligaments and muscle groups. X-ray changes consist of periarticular swelling, joint space narrowing, generalized demineralization and bony erosion.

Clinical Features[18]

Pain is the most frequent complaint in patients with an arthritic hip. Pain arising from osteoarthritis develops insidously. Initially it is intermittent and relieved by rest and mild analgesics. The pain is located over the trochanter, or groin, or referred to the knee, and is aggravated by movement. Often patients may complain of night or rest pain. In primary osteoarthritis, patients rarely become symptomatic before 40-50 years of age. One-third may have bilateral hip disease.

In rheumatoid arthritis the features are less characteristic. Single joint involvement is rare. The disease process is noted for remissions and exacerbations, and great variation in areas of involvement and rate of progression are common. Fatigue, malaise weight loss, and early morning stiffness would be expected.

In both processes, hip motion is limited. The earliest findings would be loss of internal rotation and extension. Thigh atrophy is usual. An antalgic as well as a positive Trendelenburg gait likewise

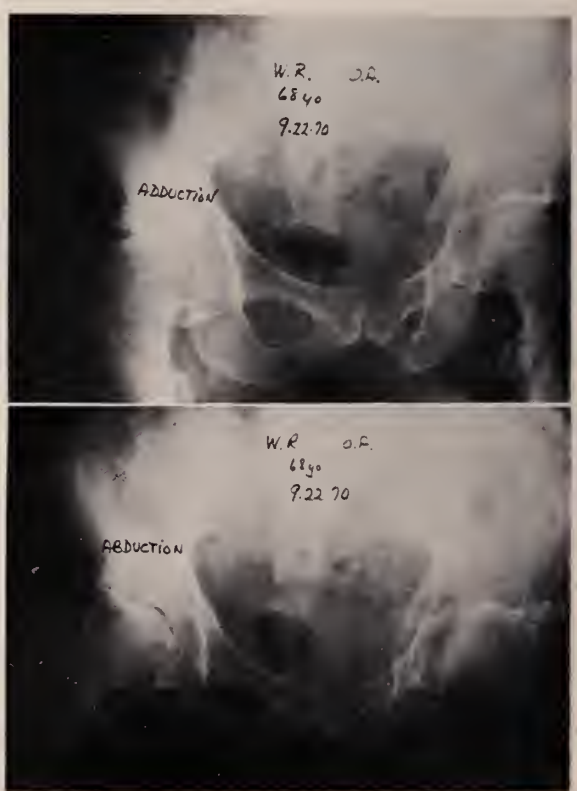
is frequent.

Indications for Surgery

Surgery for the patient with an arthritic hip is indicated to relieve pain, to correct and prevent deformity, and to maintain and regain mobility. The enthusiasm for new surgical techniques must not obscure the benefits of conservative treatment. In the patient with an arthritic hip, weight reduction, muscle strengthening exercises, analgesics, and the use of a cane are helpful. The use of a cane in the opposite hand of the involved hip is an effective method of reducing the load on the hip joint.[29] A push on the cane will produce a moment in the same direction as that produced by contraction of the abductors on the contralateral side. As Blount has noted,[8,9] the static force normally present on a hip of 85 pounds can be reduced to 66 pounds by a downward push on the cane of 38 pounds. Finally the management of the total patient rather than a single arthritic joint must be stressed. In the rheumatoid arthritic patient with a painful hip, proper medical evaluation and treatment should be well under way before considering reconstructive surgery.

Types of Operations

Synovectomy and Soft Tissue Procedures



Early synovectomy, particularly in the juvenile arthritic patient, might be considered for the ease of persistent, painful synovitis, unresponsive to medical management. Experience with this procedure is not widespread, although Albright[1] has recently presented a limited series that suggest further trials are indicated. There is little evidence to suggest that surgical dislocation of the hip to facilitate the synovectomy has lead to avascular necrosis of the femoral head. Soft tissue procedures, consisting of muscle releases, tenotomies, capsulotomy, and neurectomy, have proven of some benefit in relieving hip pain in the osteoarthritic patient.[23,27] Their effect for the most part is usually shortlived. These operations are of greatest benefit when combined with more definitive procedures.

Hip Fusion[20,33]

Hip fusion is an effective and predictable method for the treatment of degenerative arthritis of the hip joint. It may be indicated when the arthritis is confined to one hip, destruction of the hip is marked, motion is limited, and pain is severe. It finds more use in the younger individual whose work would require heavy labor. Successful arthrodesis can be expected to produce a stable, pain-free hip. In rheumatoid arthritis, with multiple joint involvement, and usually bilateral hip disease, arthrodesis of a single hip is not justified.

Osteotomy[9,14,19,28]

The principle of osteotomy is one of realigning the joint relationship to that resting or weight bearing position that improves or maximally restores the joint space radiographically. It is presumed that the radiographic appearance of a widened joint space denotes a regeneration of joint cartilage. The operation may entail an abduction, displacement, or rotation repositioning (Figure 1-4). The optimal position of the osteotomy is in the inter—or subtrochanteric area. Recent evidence suggests that the benefits of osteotomy might involve circulatory and biochemical alterations in bone and cartilage[30] as well as biomechanical factors brought about by change in head-shaft relationship.

Figures 1 (top) and 2—Xrays of the right hip in a 68-year-old male patient with severe painful osteoarthritis demonstrating an apparent improvement in the joint space width to a greater degree in abduction.

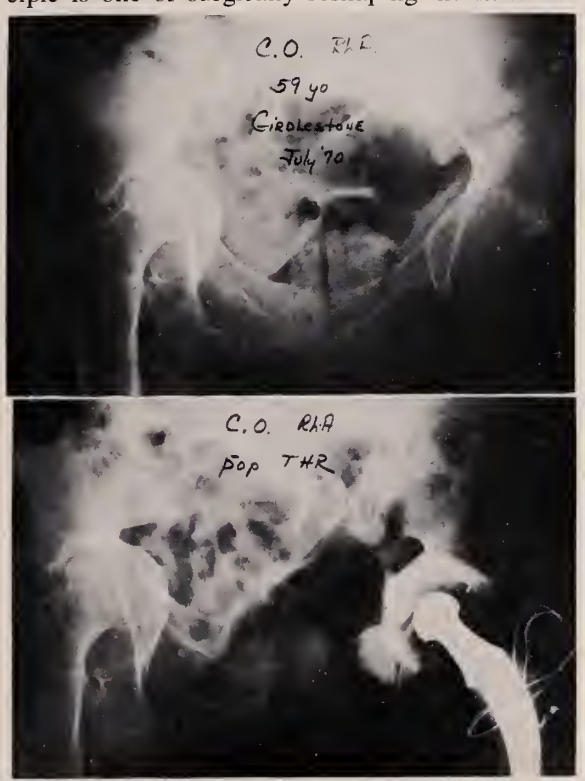
The indication for this procedure would involve significant and disabling arthritic hip pain in a patient that has at least 60 degrees of hip flexion. Following surgery, pain relief and improved ability to ambulate are to be expected. There is little change in the amount of hip motion, although cyst formation and sclerosis are reversed. The use of compression fixation techniques facilitates healing of the osteotomy and allows early ambulation. Partial weight bearing with crutch support is necessary for several months until bony union is solid.

Osteotomy has proven a poor procedure in the management of rheumatoid hip disease. The basic pathology is not altered by this procedure and consequently symptoms are not relieved.

Excisional or Resection Arthroplasty

Resection of the femoral head and neck is rarely indicated as a primary procedure for arthritis of the hip. Its value for the most part rests as a salvage operation for treating sepsis developing after mold arthroplasty or other reconstructive procedures. It will produce a moveable, relatively pain-free hip, but the patient will need external support because of gait instability and limb shortening (Figure 5-6).

Femoral Head Replacement[7,10,17,24,32]



Femoral head replacement arthroplasty for the management of the rheumatoid hip is a poor procedure. The bone in rheumatoid arthritis is usually quite osteoporotic and cannot be expected to support a metallic implant. Pain developing from prosthetic loosening and migration of the femoral head into and through the acetabulum occurs frequently (Figure 7-8). In the younger individual with degenerative arthritis secondary to aseptic necrosis, femoral head replacement might be the preferred method providing the acetabulum is relatively uninvolved by the arthritic process.

Interpositional Arthroplasty[3,4,5,7,21,24,32]

Interpositional, mold or cup arthroplasty remains a valuable procedure in the treatment of arthritis of the hip joint (Figure 9-10). The principle is one of surgically reshaping the head and

Figures 3 (top) and 4—The plan for an adduction osteotomy is outlined preoperatively. The approximate wedge of bone to be removed in order to assure an abducted position of the head in relation to the shaft is marked. The osteotomy is then securely held by a compression plate. The clinical result to date has been gratifying.

Figures 5 (top) and 6—Xrays demonstrate a Girdlestone resection of the left hip performed in a rheumatoid arthritic patient because of severe pain and limitation of motion. Following surgery the pain persisted and ambulation was difficult because of instability. Total hip replacement has furnished a stable, pain free, mobile hip.

acetabulum, interposing a metallic cup, followed by relief from weight bearing for a period of several months to allow fibrocartilage to form over the acetabulum and femoral head. In the younger rheumatoid patient with unilateral hip disease and little involvement of other joints, and in the active individual with degenerative arthritis, it is a useful procedure. The requirements of rehabilitation are great, and limited weight bearing with crutch support for four to six months is desirable. Pain relief, increased mobility, and improved gait can be expected in the majority of patients if properly selected. Results from bilateral cup arthroplastics in rheumatoid patients are less satisfactory and revision of the cup by secondary procedures because of limitation of motion is often necessary.

Complications of cup arthroplasty are similar to any type of hip surgery. One possible advantage, however, is the possibility of salvaging a cup after sepsis.[22] This is usually impossible after other methods of implant surgery and the implant in those cases must be removed.

Figures 7 (top) and 8—An Austin-Moore prosthetic replacement in a 57-year-old rheumatoid arthritic patient has resulted in prosthetic migration through the acetabulum. Total hip reconstruction with firm fixation of the components with methylmethacrylate (outlined in the dotted areas) has salvaged a difficult problem.

Total Hip Replacement[11,12,15,25,26,31,34]

The recent advent of total hip replacement pioneered by Charnley, McKee-Farrar, and Ring, have revolutionized the othopedic approach to the arthritic hip. The principle is replacement of the femoral, as well as the acetabular surface with an inert material of satisfactory design, firmly fixed to the bone with a plastic cement, methylmethacrylate. A rigid bond between bone and implant is essential and serves to distribute the stresses over the broad area providing a gradual transition of stress between prosthesis and bone. The present available models consist of either a metal to high density polyethylene or a metal to metal joint.

Generally, total hip replacement arthroplasty would be favored for the severe, symptomatic degenerative hip in a patient older than age 55. Patients with severe rheumatoid arthritis involving multiple joints, and patients with failed, painful prosthesis, might be considered for this type of surgery at a younger age.

Figures 9 (top) and 10—Mold arthroplasty has furnished this rheumatoid arthritic patient with a pain free and mobile left hip. Periarticular ossification and medial migration of the cup has not compromised the result to date.

The results for this type of operation are predictably excellent. Most authors report greater than 90% of the patients are completely or almost completely relieved of all pain, and a similar percentage of patients will notice a greatly increased range of motion and an improved ability to ambulate. In the rheumatoid arthritic patient the ability to walk great distances may not be increased because of the multiple joint involvement, but this group of patients will ambulate in a limited area with greater agility and freedom from pain. Long-term results are not available. From the experience of others, which is now approaching eight years, it appears that tissue reaction to the methylmethacrylate is not objectionable. With the use of a plastic acetabulum socket, a minimal projected wear had been estimated as 25 years.[12] Replacement of the acetabulum component is possible. However the long-term effects from debris accumulation around the joint from socket wear is not known.

It would appear that this procedure, properly executed, can produce superior results that are unmatched in consistency by other methods. Until long-term results are known, however, restraint in the use of this technique particularly in younger individuals, is desirable.

Complications

Complications following hip surgery would include thromboembolic problems, infection, periarticular ossification, nonunion of osteotomies and prosthetic dislocation, or loosening. Thromboembolic disease occurs frequently following hip surgery and prophylactic anticoagulation has been advocated.[16] Sepsis developing after hip surgery can usually be managed satisfactorily with closed suction irrigation techniques.[13] Sepsis following total hip replacement, however, is a major catastrophy. Salvage is rarely possible short of removing all the components and cement and converting the arthroplasty into a resection.[2] With meticulous attention to surgical technique, control of operating room traffic, and proper operating room air filtering systems, infection can be reduced to a level below 1%. The merits of laminar flow operating room facilities in reducing infection have not been firmly established. On the other hand, prophylactic antibiotics would appear to be valuable in limiting the incidence of this complication. Infection may not become manifest until as long as one or two years after surgery. Therefore, continued follow-up by the physician and surgeon is essential.

Summary

The indications, prognosis, and possible complications of reconstructive surgery for the arthritic hip have been outlined. Careful evaluation and assessment of each patient, along with thorough understanding of surgical principles and goals, is paramount to a successful operative result.

Vitreous Floaters and Flashing Lights

Vitreous Collapse and Sequelae

DENNIS M. ROBERTSON, M.D.*

UNDER ORDINARY CIRCUMSTANCES, one is not aware of the many imperfections in his own ocular media. With the exception of the aqueous humor, all of the ocular media are less than perfectly transparent, because they are composed of tissues containing cells with their nuclei. Opacities toward the front of the eye, involving the cornea and lens, even when of moderate size, frequently are not subjectively recognized as opacities, because the umbra of their shadows do not fall on the retina. In general, small opacities must be located within the vitreous cavity before they cast a shadow on the retina and are subjectively appreciated. Vitreous opacities are mobile (within limits) and, accordingly, are recognized by the patient as moving or floating spots; hence, the term "floaters." Spots, specks, or defects in the vision that appear stationary to the patient usually are not due to vitreous opacities. These stationary opacities, not the subject of this discussion, may indicate significant pathologic changes elsewhere than in the vitreous and merit investigation to determine their cause.

Most vitreous opacities (floaters) are entirely harmless, and the patient needs nothing more than reassurance. However, they may indicate serious ocular disease. The problem, then, is to establish which of them are significant.

Anatomy of Vitreous Cavity

Basically, the vitreous is a transparent gel in which there is suspended a solution of salts, plasma proteins, and hyaluronic acid. Its skeleton consists of a fine meshwork of interlacing collagenous fibrils. Its cellular makeup is confined to a few relatively large flat cells situated anteriorly within the superficial layers of the vitreous. Normal vitreous contains no blood vessels.[1]

From this information, one can appreciate, then, that floaters may arise from two sources: (1) from within the vitreous itself, because of alterations in its structure, most usually a collapse of the vitreous body, with condensation of collagen fibrils, and (2) from cells or debris invading the vitreous cavity from elsewhere: for example, clumps of leukocytes appearing in response to an inflammation, such as uveitis, or aggregates of erythrocytes and fibrin strands resulting from hemorrhage into the vitreous cavity.

Relationship of Vitreous Body to Retina

The vitreous body and the retina are intimately associated by virtue of a structure called the inner limiting membrane of the retina. This membrane is composed of both the cortical fibrils and mucoproteins of the vitreous and the plasma and basement membranes of the innermost cells of the retina (Muller cells and astrocytes). This vitreoretinal union, though delicate, is a definite

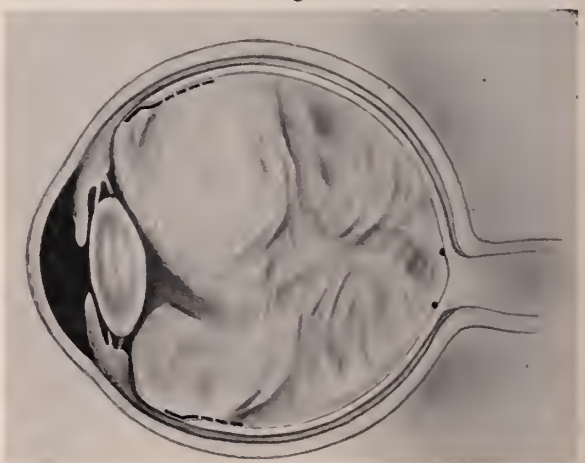

Fig. 1—Relationship of vitreous to other structures of eye. Normally firm vitreoretinal adhesions at region of ora serrata and also at optic nerve are indicated by solid lines anteriorly and black dots posteriorly. Interrupted line indicates posterior extension of relatively firm anterior vitreoretinal adhesion that occurs with aging and disease.

*Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
See editorial, page 344.

one, but it is relatively firm only anteriorly near the ora serrata, and posteriorly in a small area about the optic nerve head (Figure 1). The union of the vitreous with the retina becomes less firm in its middle and posterior thirds after the second decade. Contrariwise, with increasing age or in the presence of inflammatory disease, the relatively firm anterior adhesion at the ora serrata generally extends further posteriorly[2] (Figure 1).

Changes in the Vitreous

Syneresis

Liquefaction, more properly called syneresis, and collapse of the vitreous with posterior separation of the vitreous from the retina occur naturally with aging and high myopia. These changes may also occur after trauma to the globe or in association with other pathologic conditions, such as uveitis. Posterior vitreoretinal relationships are such that, when syneresis and posterior vitreous collapse occur, interruption of the normally delicate union between the retina and the vitreous generally will not produce complications from traction on the retina. However, significant bleeding may occur if one of the superficial capillaries is torn because of excessive traction on the superficial retina when the vitreous detaches. Whether hemorrhage occurs or not, a ring-shaped vitreous opacity on the posterior face of the detached vitreous frequently can be seen with the ophthalmoscope (Figure 2). This ring represents condensed vitreous that formerly was attached to the peripapillary retina.

Anteriorly, where the vitreoretinal bond is relatively strong, vitreous collapse may cause traction on the retina sufficient to tear some of the superficial blood vessels in the retina and occasionally to produce full-thickness retinal tears (Figure 3). Because retinal tears are precursors to retinal detachments, such an occurrence is obviously serious.

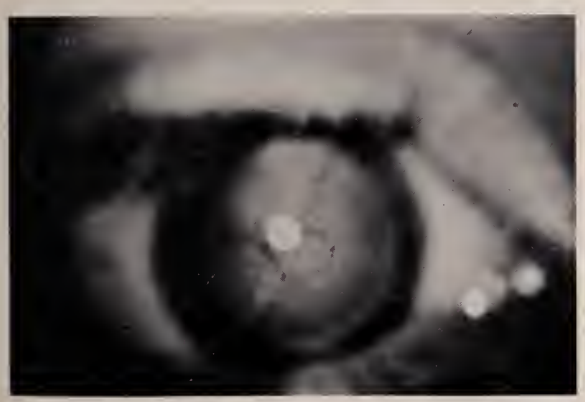

Fig. 2—Ophthalmoscopic view of ring-shaped vitreous opacity associated with posterior vitreous separation. This condensed vitreous ring formerly was attached at peripapillary retina.

Fig. 3—Superior vitreous collapse and retinal tear caused by traction of vitreoretinal adhesion.

Condensation of Vitreous Framework

Condensation of the vitreous framework to form entoptically visible floaters, though considered to be a normal phenomenon in the aged, also occurs in younger persons.[3] Generally, these vitreous changes are insidious and produce only subtle symptoms. Most persons with floaters have recognized them for years. They are usually described as specks or strings with occasional dot-like enlargements. Such floaters are usually not significant. However, floaters that appear suddenly and in great numbers are always significant. Acute floaters may appear as a web or lace-like mesh or simply as a shower of small opacities. Generally, these symptoms indicate a hemorrhage into the vitreous, a sudden collapse of the vitreous body, with or without hemorrhage, or an acute inflammatory reaction with cellular exudation into the vitreous. Possible complications resulting from vitreous collapse must be carefully investigated, and the cause of inflammation or bleeding must be established.

Hemorrhage

Hemorrhage into the vitreous may occur in a multiude of conditions. Perhaps one of the more common conditions is diabetes mellitus, in which some of the abnormal, new vascular channels may suddenly begin to bleed. Acute vitreous collapse is another common cause. Other causes of vitreous hemorrhage include hypertension, occlusion of the central retinal vein, blood dyscrasias, trauma, and others too numerous to mention.

Inflammation

Symptoms of floaters caused by aggregates of leukocytes may be no different from those that

accompany intravitreal hemorrhage. A posterior uveitis may occur abruptly from various complex causes. If a focal uveitis is threatening the macula, prompt treatment may be extremely important.

Other

Causes of vitreous opacities other than those mentioned include asteroid hyalitis (of little significance, usually unilateral and frequently not appreciated by the patient, though the relatively large snow-white opacities are easily recognized by the examiner), amyloidoses, and foreign bodies, including parasites. Tiny glittering opacities (probably in some instances cholesterol crystals), which settle rapidly, are characteristic of synchysis scintillans, but this is uncommonly seen and occurs primarily in eyes severely injured by disease or trauma.

Symptoms of Light Flashes with Floaters

If vitreous opacities appear suddenly and are accompanied by a subjective sensation of light flashes, one should suspect an acute vitreous collapse and possible sequelae. Usually, the flashes of light occur in the temporal periphery, appear abruptly and are gone in one or two seconds. They may recur many times during the day or intermittently over a period of several days. Light flashes are probably caused when the vitreoretinal union becomes interrupted and when the collapsed vitreous body "bumps" into the retina during eye movements. Such flashing lights by themselves are not uncommon. They are frequently observed by older persons, especially at night, and, in such instances, they usually are insignificant.

When flashes appear acutely and in association with the sudden appearance of floaters, it suggests that the vitreous body has suddenly collapsed and begun to separate from the retina. (These light sensations should not be confused with the scintillation scotoma seen by patients with migraine. The latter are a specific type of visual disturbance, which present bilaterally and symmetrically as a zigzag pattern of shimmering lights, occasionally colored but more often not, lasts 15 to 30 minutes, and frequently, but not always, precedes a typical migraine headache.)

Sequelae of Vitreous Collapse

Several studies have shown that 10 to 15% of all eyes with symptoms from an acute vitreous collapse have retinal tears of one variety or another[4-6] (Figure 4). About one third of the eyes with horseshoe tears accompanying such an acute symptomatic vitreous collapse develop retinal detachment.[7-9] With special techniques, an ophthalmologist usually can recognize these tears and institute treatment in an effort to prevent subsequent retinal detachment. If a detachment has developed, the patient usually will notice a shadow that most frequently ascends from the inferior visual field. Provided the detachment is recognized early, when it is confined to the periphery and spares the macula, it usually can be satisfactorily treated, with excellent visual results. However, when the detachment has extended posteriorly to involve the macula, visual results after retinal reattachment are often disappointing. Thus, early referral in such cases is essential, for the optimal time to initiate treatment is at the hole stage, before the retina has actually detached.

Summary

Vitreous floaters are a common occurrence in the general population. Most are related to aging changes in the vitreous, appear insidiously,

Fig. 4—Fundus drawing showing two types of retinal tears seen with acute vitreous collapse. Along 3 o'clock meridian, there is a horseshoe tear with a small amount of free blood along its posterior border. Below tear, a round hole with its operculum is present. Operculum represents a plug of retina which, by virtue of a strong vitreoretinal attachment, has been torn completely away from surrounding retina. Vitreous still exerts traction on flap of horseshoe tear.

and are of little significance. However, acute symptoms of vitreous floaters that present either as a web, lace-like opacity or as a shower of spots should be considered of serious importance until the cause is diagnosed. Possible causes include intravitreal hemorrhage, uveitis, or, especially when accompanied by flashes of light, acute vitreous collapse, with attendant complications including retinal tears. The sudden appearance of floaters is always significant, though not necessarily always serious. Unless etiologic factors are readily apparent, these patients should be referred to an ophthalmologist for further evaluation.

IT'S THE LAW

Physician Not Liable for Failure to Diagnose Tumor

The patient was involved in an automobile accident with injuries to the neck and right shoulder. He was seen and treated for a whiplash injury of the neck. He was seen by a second physician in consultation four months later. The patient stated that at this time his condition was improving. The examination of his shoulder was normal. Xrays were not ordered. Four months later the patient returned with more difficulty with his shoulder. Xrays were made which revealed a giant-cell tumor at the head of the humerus.

The patient brought a malpractice action against the examining physicians contending he suffered damage because of the physician's alleged negligence in failing to diagnose and treat the tumor of the shoulder. The trial court decided in favor of the physician and the patient appealed. The appeal court ruled that the medical record indicated that the physicians had taken usual medical care and that no negligence or malpractice was involved.

Multiple Primary Malignancies

An Unusual Combination

P. K. SPANOS, M.D.,* J. FEEMSTER, M.D.,* C. E. WEIGENT, M.D.* AND G. LYONS, M.D.*

BILLROTH FIRST RECOGNIZED the occurrence of different primary malignant tumors in one patient in 1869.[1] He was also the first to set forth the criteria of definition of multiple primaries. He stated that each tumor must be histologically different, that each must arise in a different location and that each must produce its own metastases.[1]

Today the most widely accepted criteria of multiplicity are those defined by Warren and Gates[5] (1932) in a review of the literature on multiple cancers up to that time. Their criteria, which differ little from Billroth's, were as follows: (1) Each tumor must present a definite picture of malignancy; (2) Each tumor must be distinct; and (3) The probability of one being a metastasis of the other must be excluded.

Since that time, numerous papers have been written on the subject. Moertel (1964) estimated the number of multiple cancers reported to that time in excess of 12,000.[4] Mersheimer, and coworkers (1964) reported on 140,000 cancer patient records obtained from the Connecticut Cancer Case Registry.[3] They found a total of 4,461 patients with multiple primaries but only five percent of these patients had more than two primaries.

Although multiple primary malignancies are not a rare entity their appearance is an unusual phenomenon which raises the question of: (1) predisposition in a patient with a single malignancy towards development of a second tumor; and (2) multicentricity of origin in certain tissues. Several authors have attempted to answer these questions and there is uniform agreement that multicentric cancers—that is cancers confined to the same tissue—occur more frequently than chance alone would allow.[4,6] Such uniform agreement has not been reached regarding the occurrence of a second primary in different tissues or organs.

Watson reviewed his cases in 1953, and concluded that there was no constitutional predisposition to multiple cancers of different systems and that no immunity was conferred by a first cancer.[6]

The patient presented in this report is of interest because of the unusual combination of tumors with which he presented.

Case Report

A 74-year-old retired Veterans Administration Hospital employee was admitted to the Veterans Administration Hospital for evaluation of black tarry stools for 1.5 months and epigastric bloating of a year's duration. During the same period the patient noted increased constipation, fatigue and anorexia. Over the last several months he had noted a ten pound weight loss. The patient denied any nausea, vomiting, hematemesis or abdominal pain.

Past history revealed an episode of malaria in 1917. In 1955, he was hospitalized for fulguration of four rectal polyps at 3, 6, 13 and 14 cm which were benign on miscroscopic examination. Since then he was followed periodically in the proctology clinic without evidence of recurrent polyp formation. The patient was admitted in February, 1969 because of suprapubic pain, nocturia and hesitancy. Cystoscopy revealed a tumor on

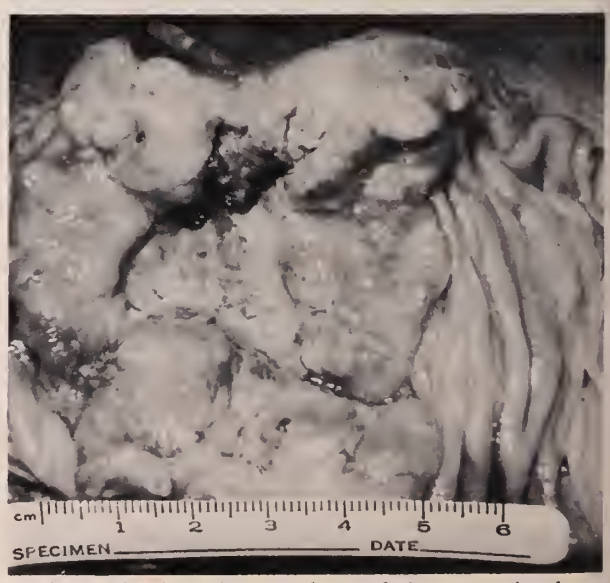

Fig. 1—Section of gross photo of the resected colon carcinoma.

See editorial, page 341.

the left lateral wall of the bladder. A transuretheral resection (TUR) of the bladder tumor was carried out which revealed a transitional cell carcinoma grade I.

In April, 1969 he had a second TUR for obstruction secondary to benign prostatic hypertrophy.

In November, 1969, the patient was readmitted to the Urology Service for biopsy of suspicious lesion of the right lateral bladder wall. The lesion was a benign papilloma.

Physical examination on this admission revealed a well-nourished, well-developed elderly gentleman in no acute distress. His BP was 110/70 with a regular pulse of 80. Pertinent physical findings revealed external strabismus of the right eye with a 1 cm, soft, freely movable mass over the right lateral upper eyelid. The chest was found to be increased in the AP diameter with decreased breath sounds. There were no rales nor rhonchi present. There was a grade II/VI systolic murmur along the left sternal border. There was a tender 5 cm abdominal mass in the left upper quadrant near the midline. The abdomen was otherwise unremarkable. The remainder of the examination was within normal limits. Xray examination of the upper gastrointestinal tract revealed a transverse stomach with a small duodenal diverticulum but no other pathology was noted. A barium enema revealed an 8 cm constricting lesion of the upper part of the descending colon. A sigmoidoscopic exam was within normal limits to 20 cm.

Surgical Findings

The patient was taken to the operating room on April 22, 1970, with a preoperative diagnosis of carcinoma of the descending colon. Two separate tumor masses were identified at the time of surgery. One mass arose from the distal jejunum and had a marked inflammatory reaction in the surrounding mesentry with adherence of the involved loop to the mid-transverse colon. The other mass was located in the area of the splenic flexure and extended through the wall of the bowel to involve the anterior parietal peritoneum. There was enlargement of the regional lymph nodes but the liver and the rest of the abdomen were free of any gross evidence of tumor.

A left hemicolectomy and segmental small bowel resection were done. The patient did well following surgery and was discharged from the hospital 15 days later. He was given a course of chemotherapy (cytoxan) and is currently without evidence of any recurrence of disease.

Pathology

The specimen consisted of a segment of colon measuring 75 cm in length and an attached segment of small bowel measuring 25 cm in length.

There was an ulcerating tumor mass measuring 6 cm in length and encircling the colon 10 cm from the distal line of resection (Figure 1). Mi-

Fig. 2—Adenocarcinoma of the colon.

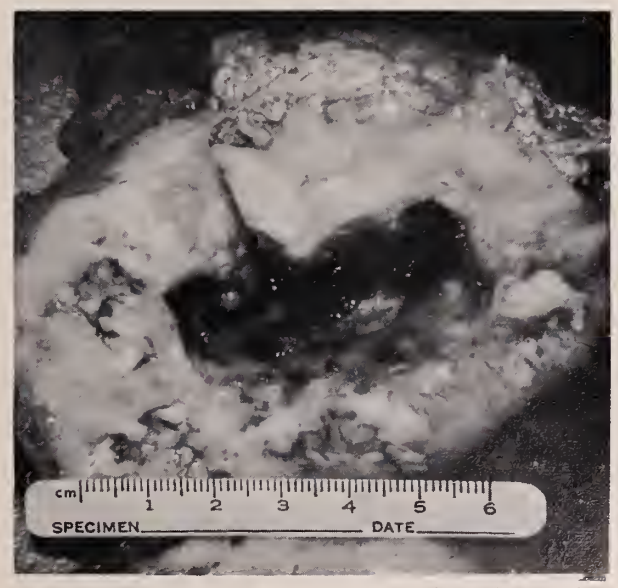

Fig. 3—Reticulum cell sarcoma of small bowel.

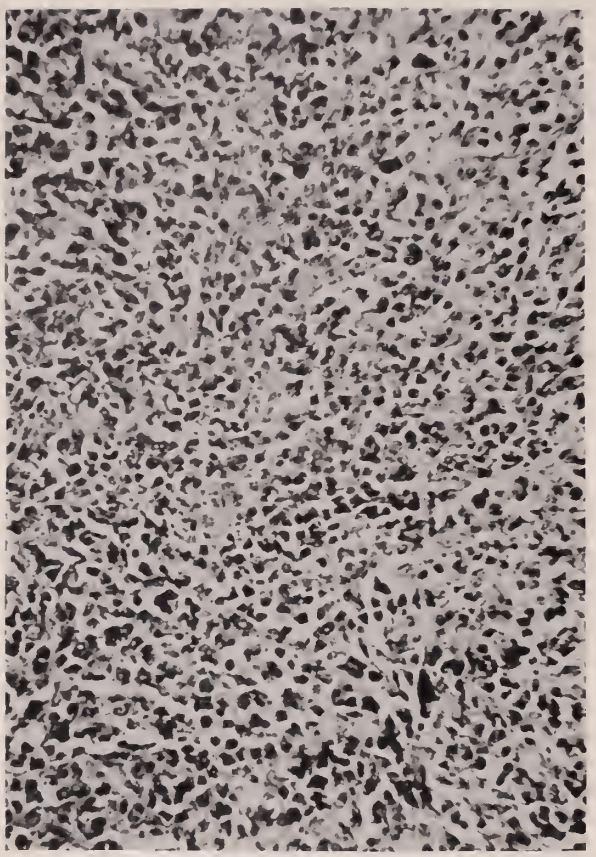

Fig. 4—Microscopic section of reticulum cell sarcoma of small bowel.

Fig. 5—Microscopic section of the reticulum cell sarcoma with reticular stain.

croscopic sections showed an infiltrating adenocarcinoma (Figure 2) extending through the bowel wall. Metastatic adenocarcinoma was present in one small adjacent lymph node.

Within the segment of small bowel was a large tumor mass measuring 9 cm in length and encircling the small bowel. There was extensive ulceration of the small bowel mucosa at the margins and the edges were raised and irregular. On transection the bowel wall measured from 2 to 3 cm in thickness and appeared to be completely replaced by soft pink-white tumor tissue with foci of necrosis (Figure 3).

Microscopic section showed the tumor to be composed of solid sheets of abnormal reticulum cells (Figure 4.). The tumor extended through the wall into the adjacent fatty areolar tissue. There were large areas of necrosis within the tumor. A reticulin stain showed numerous reticulin fibers between the individual tumor cells (Figure 5).

Lymph nodes taken from the portion of the bowel mesentery and omentum submitted with the specimen showed hyperplastic changes without evidence of tumor.

Conclusion

A case is reported of a patient with three different primary tumors believed to be the first with the following combination; 1) Transitional cell carcinoma of the bladder; 2) Reticulum cell sarcoma of the small bowel; and 3) Adenocarcinoma of the large bowel.

Multiple primary malignancies can and do occur concomitantly or, separated in time, in different tissues, in a significant number of patients presenting with apparent single organ disease.

The malignant stage of later appearing primary tumors is an index of the quality of follow-up care of the previously treated patient.

Surgery is a rational form of treatment in patients with multiple primary tumors. Each tumor should be approached with respect to its own biologic nature as well as to its effect on the patient as a whole.

The Ruptured Disc Syndrome

EVAN S. ELLISON, M.D.*

BONY CONSTRUCTION of the spinal canal causes symptoms of nerve root pressure in the lumbar spine. Narrowing can be produced by a congenital anomaly, trauma or osteoarthritis. The stenosis may be present for a long time prior to the onset of symptoms. Further constriction of the canal by a bulging disc may initiate pain. In some cases the bony canal narrowing can be seen on the spinogram or standard views prior to surgery, but often the condition is not diagnosed until the time of operation.

Recent Studies

Schatzker and Pennal described narrowing of the spinal canal in the dorsoventral diameter or in the lateral recess with cauda aquina compression.[1] Jones and Thomson have attempted to assess spinal canal narrowing by measuring the A - P diameter of the canal and interpedicular distances in the prcoperative Xrays.[2] Macnab has documented nerve root kinking about the vertebral pedicle which can occur with narrowing of the disc space. He also described articular process impingement on the nerve root associated with disc space narrowing.[3] Schlesinger described first sacral nerve root pressure due to anatomical variation in the lateral bony recess.[4]

Symptoms

The symptoms of stenosis of the bony canal are similar to the classical symptoms of ruptured disc. The nerve root distribution of pain and numbness tends to be more constant and unrelieved by rest or a flexion brace. It is possible for the symptoms of spinal canal stenosis to have a sudden onset in a previously normal persons. The bony narrowing may have been present asymptomatically, but the slightest bulging of the disc will produce an acute onset of symptoms. The same amount of bulging in a normal spinal canal would be asymptomatic. There are no differentiating physical findings betwecn spinal canal stenosis and ruptured intervertebral disc.

Operation

At the time of the operation it is necessary to carry the laminectomy laterally far enough to visualize the lateral margin of the dura and nerve root without retracting either medially. This will allow direct visualization of any lateral, posterior or anterior bony canal narrowing. Sometimes the medial portion of the facet will have to be sacrificed. Before removing the overhanging bone it is often necessary to elevate it off of the constricted nerve root by means of the shoe of the Kerrison rongeur. As this is accomplished the indentation of the nerve root by the protruding

Fig. 1-A—Note lateral indentation of dye column at the L4-L5 interspace.

Fig. 1-B—Note minimal indentation of dye column anteriorly indicating minimal disc protrusion.

Fig. 2-A—Note narrowing of bony canal by bony prominence adjacent facet.

bone becomes apparent. This phenomenon can also be caused by hypertrophy of the superior laminal plate posteriorly. It can also be found in scoliosis with lateral wall deformity. Osteoarthritic changes in the articular facets can produce this constriction by narrowing the lateral recess of the spinal canal at the point of exit of the nerve root or by indenting the dura medially. The spinal canal may be oval shaped with its largest diameter in the anteroposterior direction. This can in turn be associated with hypertrophy of the ligamentum flavum and facet and secondary pressure on the nerve roots laterally. The spinal canal may be narrowed in the anteroposterior plane and elongated laterally producing pressure on the nerve root anteriorly or posteriorly. The following three cases are examples of this condition.

Case Reports

Case 1

A thirty-six-year-old man had pain intermittently in the left buttock and left leg for six weeks. The pain was located over the posterior aspect of the left thigh and calf. The foot was not involved. He had backache on two occasions over the past six years but no previous radiation of pain into the legs. The present pain was aggravated by coughing as well as activity. Lying down relieved the pain. The pain was progressively worse.

Fig. 2-B—Note minimal indentation of dye column anteriorly.

Examination revealed loss of the normal lumbar curve. There was no motion of the lumbar spine on forward or side bending. There was spasm of the erector spinae muscles to palpation. The left calf measured 16 inches and the right 16½ inches in their greatest circumference. There was a positive straight leg raising test on the left at 30 degrees. The knee jerks and ankle jerks were equal and normal.

Xrays showed a large posterior defect in the dye column at the level of the 4-5 interspace on the left side (Figure 1). At surgery a hypertrophy of the superior laminal plate was found on the left side corresponding with the defect in the dye column. This was removed and the nerve root was completely decompressed. The patient was able to return to his former job two months after the operation with occasional mild twinges of pain in his left thigh which were receding.

Fig. 3-A—Note indentation of dye column by bony prominence adjacent facet.

Case 2

A forty-four-year-old man noted the onset of back pain while playing handball on March 7, 1969. The pain was located over the lateral aspect of the right buttock. It stopped at the thigh. There was numbness and tingling in all of his toes and in the sole of his right foot. Coughing did not affect the pain. Bending aggravated the pain. His past history revealed that he had scoliosis since childhood. Examination revealed spasm and splinting of the erector spinae muscles of the lumbosacral spine. There was scoliosis. There was no motion of the lumbar spine on forward or side bending. There was loss of the normal lumbar curve. The knee jerks were diminished bilaterally. The right calf measured 15¼ inches and the left 15¾ inches in their greatest circumference. There was a positive straight leg raising test on the right at 40 degrees. There was tenderness over the right sciatic notch.

Myelogram showed bilateral narrowing of the bony canal secondary to the scoliosis (Figure 2). At surgery

Fig. 3-B—Disc protrusion apparent on lateral view which compressed the nerve root against the bony prominence on the right side.

the bony narrowing of the canal was found as indicated on the myelogram. The narrowing indented the nerve root which was completely decompressed. The disc space was completely closed posteriorly and was not indenting the nerve. For this reason the disc was not removed. Six months after the operation the patient was playing handball and complained only of occasional twinges in the right thigh.

Case 3

A fifty-six-year-old man had pain in his back and right leg after unloading a truck three months prior to surgery. He had intermittent back pain for many years. The pain never radiated into the legs until the present attack when it extended down the posterolateral aspect of the right thigh into the right calf and into the lateral aspect of the right foot. It was constant, dull, and aggravated by activity. There was no paresthesia. Coughing aggravated the pain. There was also pain in his left buttock but much less than in the right. The patient obtained temporary relief wearing a William's brace but developed pain down the anterolateral aspect of the right thigh which was relieved by taking the brace off. Examination revealed spasm and splinting of the erector spinae muscles. There was no motion of the lumbar spine on forward or side bending. There was a list to the left side. There was loss of sharp sensation over the lateral apect of the left calf and left foot. Both calves measured 13½ inches in their greatest circumference. There was a positive straight leg raising test on the right at 30 degrees and on the left at 60 degrees. The toe extensors were normal.

The myelogram showed a large defect in the dye column which was confirmed at the time of the surgery (Figure 3). There was a large overhanging ridge of bone narrowing the lateral recess and compressing the nerve root on the right side. There was a bulging disc on the left side which was removed. Two months after surgery the patient complained only of minimal numbness in the lateral aspect of the right foot and some local aching in the incisional area.

The differentiation between ruptured disc and spinal canal stenosis is of interest to the diagnostician and to the surgeon. The direct cause of nerve root pressure is a bony constriction in the spinal canal aggravated by a protruding or ruptured disc. At the time of surgery the lateral margin of the bony canal has to be removed in order to determine that there is no constriction of the nerve root. Often in performing the dissection the lamina has to be carefully elevated off of the nerve before the overhanging bone can be removed. Adequate lateral dissection permits exposure for visualizing and removing the disc and complete decompression of the nerve root.

Spontaneous Healing of Interventricular Septal Defects

Due to Nonpenetrating Trauma

BENJIE GOLDFARB, M.D.* and YANG WANG, M.D.*

RECENTLY, ROSENTHAL, Parisi, and Nadas reported the first instance of spontaneous healing of an interventricular septal defect due to nonpenetrating trauma that was documented by serial cardiac catheterization.[1] The case studied was that of a ten-year-old girl who was followed for a period of nine and one half years after a chest wall injury. Over this interval, there was a sizeable decrease in left to right shunt together with improvement in congestive failure. We recently have followed a similar case over a three and one half year period.

Case Report

A 20-year-old white male was well until November 1963 when he was involved in an automobile accident in which he fractured his sternum. He was hospitalized by his private physician and discharged after five days of observation. Two weeks later he was readmitted to the hospital in pulmonary edema. In adidtion, there was cardiomegaly, and a heart murmur was heard for the first time. He was treated with digitalis and bedrest, and on February 7, 1964 he was referred to the University of Minnesota Hospitals for further treatment.

Physical examination revealed a muscular, healthy appearing, white male. The blood pressure was 110/60. There were prominent "a" waves visible on examination of the cervical venous pulsations. A prominent right ventricular heave, a systolic thrill in the fourth intercostal space to the left of the sternum, and a palpable pulmonary valve closure were present on palpation of the precordium. On auscultation a grade IV/VI harsh, pansystolic murmur, loudest in the fourth intercostal space was heard along the left sternal border. The second sound was widely split with the pulmonic component being considerably louder than the aortic component. There was a loud apical protodiastolic gallop and a faint apical diastolic rumble.

A roentgenogram of the chest demonstrated probable biventricular enlargement with prominent pulmonary vasculature suggestive of a left to right shunt (Figure 1).

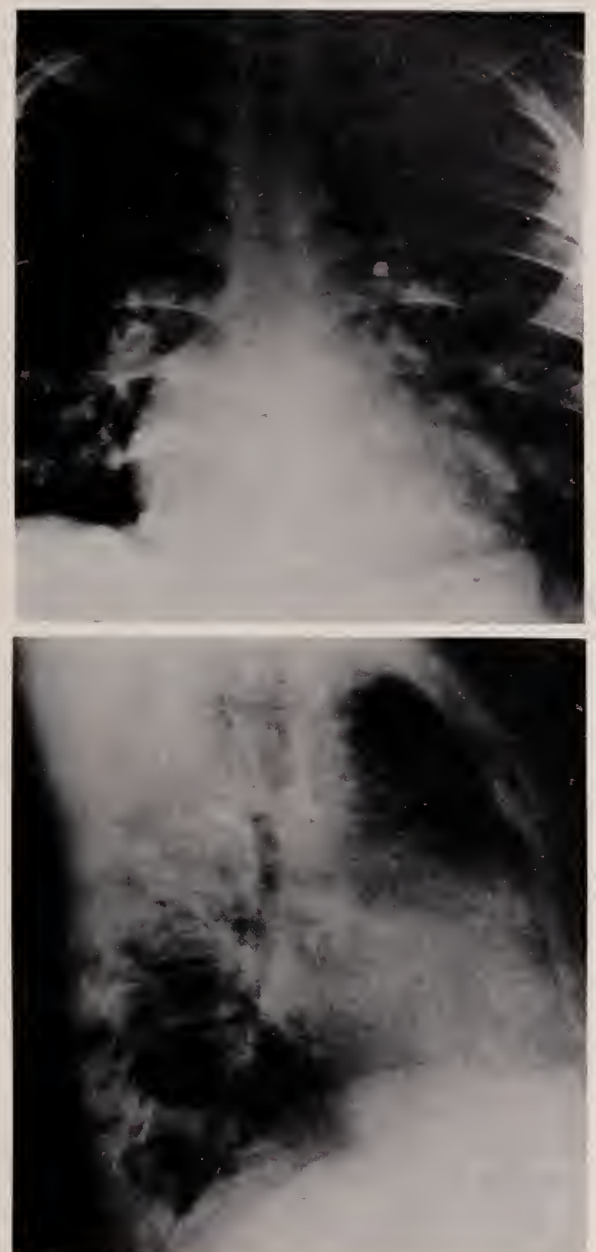

Fig. 1—Preoperative chest roentgenograms. Posterior-anterior and lateral views respectively, demonstrating probable biventricular enlargement and prominent pulmonary vasculature suggestive of left to right shunt.

*From the Cardiology Division, Department of Medicine, University of Minnesota Hospitals, Minneapolis, Minnesota.
Address for reprints: Yang Wang, M.D., Department of Medicine, University of Minnesota Hospitals, 412 Union Street, Minneapolis, Minnesota 55455.

The electrocardiogram showed left anterior hemiblock (Figure 2).

On February 11, 1964 cardiac catheterization was performed. The findings were those of biventricular failure, moderate pulmonary hypertension, and a 72% left to right shunt at the ventricular level (Table). A selective left ventriculogram further confirmed the presence of this shunt.

Fig. 2—Postoperative chest roentgenograms. Posterior-anterior and lateral views respectively, demonstrating decrease in cardiac size and decreased prominence of pulmonary vasculature.

On February 18, 1964 surgical repair was undertaken using total cardiopulmonary bypass. A right ventriculotomy was done with demonstration of eight defects of the muscular septum, ranging from 2 mm. to 2 cm. in diameter. These were closed with interrupted mattress sutures and tied over 1/16 inch teflon felt. It was noted that several defects in the region of the apex had margins of friable, soft, muscle which held stitches very poorly.

Postoperatively, the systolic murmur persisted. On chest roentgenogram there was slight decrease in cardiac

F_5 = frontal plane, distance between heavy lines = 1 millivolt; H_5 = horizontal plane, distance between heavy lines = 1 millivolt; S_{10} = left sagittal plane, distance between heavy lines = 2 millivolts; X = X axis; Y = Y axis; Z = Z axis.

TABLE
Cardiac Catheterization Findings

Date	Pulmonary Artery Pressure (mm Hg)	Right Ventricular Pressure (mm Hg)	Mean Right Atrial Pressure (mm Hg)	Mean Pulmonary Artery Wedge Pressure (mm Hg	Left to Right Shunt by Oximetry (%)	Left to Right Shunt by Indicator Dilution Curves (%)
2/11/64	70/30	70/10-20 (a wave)	13	25	69	72
3/10/64	40/20	40/0-12 (a wave)	9	12	72	71
11/5 /64	27/14	27/1-8 (a wave)	4		61	57
8/21/66	26/12	26/4-10 (a wave)	5	12	31	30

size and decreased prominence of the pulmonary vasculature (Figure 3). The electrocardiogram now demonstrated complete right bundle branch block and left anterior hemiblock.

On March 10, 1964 right heart catheterization was performed. The findings were borderline right ventricular failure at rest, a pulmonary artery pressure at the upper limits of normal, and a left to right shunt of 71% at the ventricular level (Table). The patient was treated with digoxin and a low sodium diet.

He was readmitted to the University of Minnesota Hospitals for further study on November 4, 1964. At this time there were no symptoms referable to the cardiovascular system. On physical examination the "a" wave was no longer prominent in the cervical venous pulsations. The systolic murmur was unchanged from preoperatively, and a faint apical mid-diastolic rumble persisted. The pulmonic component of the second sound was no longer prominent, and the protodiastolic gallop was no longer audible. The chest roentgenogram and electrocardiogram were unchanged.

On November 5, 1964 right heart catheterization revealed no evidence of cardiac failure at rest, a normal pulmonary artery pressure, and a 60% left to right shunt at the ventricular level (Table). Surgical intervention was refused by the patient.

During the subsequent two years he discontinued digoxin and was able to perform heavy labor as a construction worker without difficulty.

He was readmitted to the University of Minnesota Hospitals for re-evaluation on August 22, 1966. Right heart catheterization demonstrated normal pressures without evidence of failure at rest. There was only a 30% left to right shunt at the ventricular level (Table).

The patient was last seen on July 14, 1967 at which time physical findings were unchanged, and there were no symptoms referable to the cardiovascular system.

Discussion

Several previous investigators have suspected spontaneous closure of interventricular septal defects due to nonpenetrating trauma because of changes in physical findings or clinical course.[2,3,4] However, documentation of this phenomenon by serial cardiac catheterization has been achieved in only one other case.[1] This case of Rosenthal, Parisi, and Nadas was not operated upon, and, therefore, the number of defects could not be determined, although a single defect was suspected. In our case multiplicity of defects was proven at surgery.

Because the size of the left to right shunt was the same preoperatively and immediately postoperatively, it would appear that the surgical attempt at closure of the defects had little effect on the clinical course of this patient. A possible reason for failure of surgery could be the friable nature of the margins of the defects and their inability to retain sutures satisfactorily. In the future, perhaps a left ventricular approach and repair of defects from the left side might be more successful. In this way the pressure gradient between the two ventricles might prevent a patch from detaching from the margins of a defect, instead of causing detachment of a patch applied to the right ventricular aspect of the septum. Previous authors have utilized only a right ventricular approach.[5-10]

This case emphasizes the point that in carefully observed patients, early surgery is not always necessary and that medical management until the defect spontaneously heals may be the treatment of choice.

Acute Laryngeal Trauma

Its Early Management

LAWRENCE W. DeSANTO, M.D.* AND AUBREY K. BROWN, JR., M.D.†

A SYSTEMATIC APPROACH to the management of acute laryngeal trauma is available in the medical literature.[1-5] Although early treatment is the keynote to successful rehabilitation, a scarred and crippled larynx frequently is discovered weeks after an emergency tracheotomy has relieved the urgency of the situation and other injuries have been treated.

The purpose of this paper is to discuss laryngeal injuries and to emphasize the need for enactment of an early treatment program that will permit functional rehabilitation of the upper parts of the respiratory and digestive tracts.

Principles of Management

The principles of management of an injury to the upper airway are the same as those applicable to other regions of the body: (1) recognition, (2) definition of the injury, (3) careful debridement, (4) early restoration of anatomic relationships, (5) repair of disrupted mucosal surfaces, (6) planned immobilization and (7) prevention or treatment of infection. To achieve total rehabilitation, an adequate lumen with a cartilaginous framework, functional muscles and joints, and an intact nerve supply are necessary. At times, total rehabilitation may be impossible; but it represents a goal that can be approached by application of these principles.

Report of Cases

Case 1

After an automobile accident in which she was thrown into the dashboard and then through the windshield, a 24-year-old woman (married and pregnant for six months) was admitted to the emergency room. The patient was cyanotic, severely dyspneic, and convulsing. Subcutaneous emphysema extended from her chin to the middle of her thorax. After an emergency tracheotomy, appropriate specimens for laboratory studies were obtained, and roentgenograms were made. The patient was taken to the operating room where a right pneumothorax was drained, and multiple facial lacerations were repaired.

Two days later, she was seen by an otolaryngologist because she was having difficulty in talking when her tracheotomy tube was occluded and liquids were being aspirated. Indirect examination of the larynx revealed that both vocal cords were fixed in the midline position, with an opening (1 mm) of the posterior portion of the glottis. Lacerations or dislocations of the supraglottic region of the larynx were not observed. A lateral roentgenogram of the neck demonstrated narrowing of the air shadow in the region of the cricoid cartilage and upper part of the trachea (Figure 1-A). Also, minimal deformity of the body of the sixth cervical vertebra was noted. Tomograms of the larynx showed obliteration of the laryngeal air shadow by soft tissue, asymmetry of the subglottic region, and fullness in the left subglottic region (Figure 1-B).

Four days after the accident, general anesthesia was employed through the tracheotomy tube, and the midline position of the vocal cords was verified by direct laryngoscopy. A bronchoscope was introduced to the level of the cricoid cartilage, where total obliteration of the lumen with disrupted mucosa and bleeding was observed. The neck was explored by enlarging the tracheotomy, and both recurrent nerves were identified and dissected to their terminal branching at the cricothyroid membrane. At this point, continuity was disrupted, and the terminal branches of the nerves were lost. The first tracheal ring and the cricoid cartilage had separated. The cricoid cartilage was in three large pieces (Figure 1-C). These cricoid fractures were reapproximated with stainless steel wire (No. 28) placed through the perichondrium. In the lumen, the viable mucosa was reapproximated. A skin graft of split thickness was taken from the right side of the abdomen and sewed around a stent made of sponge rubber; and the stent was placed in the disrupted lumen (Figure 1-D). Then, the trachea was drawn to the reestablished cricoid cartilage to provide a solid lumen around the stent. Prior to insertion of the stent, a small tracheo-esophageal fistula of the posterior wall was detected and closed. The stent was wired in place through the thyroid cartilage and secured with a fishline suture attached to the tracheotomy tube.

After the operation, the patient tolerated nasogastric feedings well. Within 10 days, she was swallowing normally. Twelve days after the laryngeal repair, the lumen was exposed (using the suspension laryngoscope), and the stent and excessive skin were removed from the reestablished larynx. At this time, the diameter of the lumen appeared adequate, but the anterior wall con-

*Section of Otolaryngology and Rhinology, Mayo Clinic, Rochester, Minnesota.
†Scott-White Clinic, Temple, Texas.
See editorial, page 348.

tained granulation tissue. For this reason, a second stent made of sponge rubber and covered with a finger cot was inserted and secured by a wire placed through the thyroid cartilage. Two weeks later, fluctuant swelling was noted around the wire on the left side of the neck. This infection was drained, cultured, and attributed to *Staphylococcus*. A suspension laryngoscope was employed, and the stent was removed. Although a bronchoscope (7 mm) could be passed through the lumen, some granulation tissue still remained on the anterior wall, and a third stent was prepared from an endotracheal tube. It was reinserted into the lumen and wired into place through the skin above the tracheotomy tube. The drainage in the neck quickly subsided when sodium cephalothin (Keflin) (500 mg intramuscularly every six hours) was employed. The patient was able to talk through the lumen of the endotracheal tube stent, and the plugged tracheotomy cannula did not cause difficulty. The tracheotomy tube remained plugged when she was discharged 30 days after admission.

On Jan. 21, 1968, the patient delivered a full-term boy, weighing eight pounds, one ounce. Four weeks later, the tracheotomy tube and stent were removed. When she was last examined on February 1, 1968, her airway was adequate and her voice was weak but functional. Both vocal cords remained paralyzed in the paramedian position with a glottic opening of 4 to 5 mm. Revision of the scar tissue of the neck (Figure 1-E) was planned within six to nine months.

Comment

In the presence of severe injuries to other organ systems, the damaged larynx can be overlooked

Fig. 1 (Case 1). (A) Lateral view of soft tissue of neck, with *arrows* indicating loss of air shadow at cricoid cartilage. (B) Anteroposterior tomogram, with *arrows* indicating narrowed laryngeal lumen. (C) Operative view of fractured cricoid cartilage. Hook is behind posterior lamina of cricoid. (D) Sponge-rubber stent prepared for insertion into laryngeal lumen. Note split-thickness skin graft with raw surface outward, which is sewed around stent. (E) Patient four months after operation. Anterior portion of neck after decannulation of trachea.

after a tracheostomy is established. Functional rehabilitation demands early definition of the airway injury.

Case 2

A 58-year-old woman was seen in the emergency room after an automobile accident in which she was thrown into the windshield. The patient was conscious, and respiration was normal. Her most apparent injury was scalp and forehead lacerations, but a contusion was noted on the anterior portion of her neck. Subcutaneous emphysema was absent. The lacerations were repaired, and the patient was admitted for observation.

Within eight hours after the accident, progressive dyspnea and subcutaneous emphysema of the neck developed. Indirect examination of the larynx was inconclusive. A soft-tissue roentgenogram of the neck was suggestive of a cricoid cartilage fracture (Figure 2). After tracheostomy and the administration of general anesthesia, the larynx was exposed with the use of a Jackson laryngoscope. Cordal motion was normal. The subglottic region of the larynx was narrowed by edematous mucosa and dislocated cricoid cartilage fragments. The fractures were easily reduced by passage of the laryngoscope through the lumen of the subglottic region. A sponge-rubber stent in the lumen maintained reduction. A skin graft was not necessary. One stent was removed in 15 days, and the tracheostomy tube was removed two days later.

The patient has a near-normal voice and a normal airway.

Comment

A serious, life-threatening injury can be present with little external evidence. The slight contusion of the neck heralded a severe airway emergency. Some injuries can be quickly and easily repaired without open surgery.

Discussion

The larynx, pharynx, and trachea are vulnerable to laceration, incision, contusion, penetration, crush, dislocation, and disruption; and the potential causes of such trauma increase with advances in warfare, transportation, industrial equipment, and household appliances. Whereas acts of violence, athletic contests, suicide attempts, tracheotomy, and irradiation must be added to a list of civilian injuries, the automobile accident remains the principal cause of the damaged airway. Sudden propulsion into a dashboard or front seat or through the windshield, with contact of the hyperextended anterior portion of the neck, is the usual mechanism of injury.* Fractures of the thyroid cartilage occur most frequently, whereas those of the cricoid cartilage occur less often. Acute obstruction of the airway may result from fractured cartilage, hematoma, arytenoid dislocation, or recurrent nerve damage with the vocal cords paralyzed in the adducted position.

In the emergency room, the diagnosis of an injury to the upper airway begins with systematic evaluation of the larynx after the urgent problems of hemorrhage, compromise of the airway, and shock are treated. All serious injuries will influence the voice or respiration or both. An abnormal or absent voice may be due to laryngeal or cerebral damage, but the larynx must be evaluated before any voice change can be attributed to a head injury. Stridor, noisy inspiration, dyspnea, suprasternal or infrasternal retractions, and acute or chronic hypoxia also demand evaluation of the upper airway.

External examination of the larynx may reveal minimal evidence of the underlying damage. Severe injury can occur after the direct hammering of the laryngotracheal complex against the cervical vertebrae without breaking the skin. Palpation of the neck may demonstrate loss of the normal landmarks of the thyroid or cricoid cartilages, deformity, dislocation, abnormal motion, crepitation, or induration. Subcutaneous emphy-

Fig. 2 (Case 2). Lateral view of soft tissue of neck. There is a retropharyngeal soft-tissue mass with presence of air in the retropharyngeal space.

*This type of injury is preventable to a degree by the use of the seat-belt and shoulder-harness arrangement that is now available in automobiles.

sema is not indicative of the severity of the injury.

The orderly evaluation of a laryngeal injury includes roentgenograms of the neck. A lateral view will provide information concerning the position of the cartilages and any distortion of the air column. Anteroposterior views and tomograms during phonation and rest may show mobility of the vocal cords, as well as fractures and dislocation. Aspiration may indicate a tracheo-esophageal fistula, but this abnormality may be due also to an ineffective glottic sphincter. Roentgenologic use of a contrast medium is necessary to rule out the possibility of a fistula, and iodized oil (Lipiodol) or meglumine diatrizoate (Gastrografin) are preferable to barium because they produce less reaction in the lungs. These agents are less viscous; hence, a small fistula is more likely to be visible.

Examination of the larynx by the use of an indirect mirror may be possible and helpful in the cooperative, conscious patient with a controlled airway. This indirect visualization provides knowledge of glottic motion, mucosal tears, hematoma, dislocation, and distortion of the lumen. As soon as the patient's condition permits, direct laryngoscopy and bronchoscopy should be done to complete the evaluation. Direct examination within 48 to 72 hours may be therapeutic in that cricoarytenoid dislocations can be repositioned and depressed, and nondisplaced thyroid or cricoid cartilage can be *ironed out* with the instrument.

Lynch's[5] classification of three types of laryngeal trauma provides a useful framework for the application of surgical principles in the repair of injuries of the upper airway.

A Type 1 injury is a wound from without that does not involve cartilage and is without laceration or damage. Such an injury includes blunt trauma or open wounds of the anterior surface of the neck and external portion of the larynx or trachea, without fractured or displaced cartilage or mucosa. Usually, debridement and primary closure of the wound in the neck is adequate treatment. Tracheotomy often can be avoided by careful observation of the voice and respiration in anticipation of laryngeal edema or hematoma. Hyoid fractures without mucosal tears belong to this category of injury. Unless the fracture is displaced enough to narrow the airway, careful observation is all that is necessary. The prognosis for an adequate airway and voice is good.

A Type 2 injury is a wound with laceration or injury of the interior surface without displacement. Laryngeal edema and hematoma are serious hazards in the Type 2 injury with open or intact cervical skin. Careful observation and a low tracheostomy at the first sign of respiratory distress are imperative before a desperate state is reached. A large hematoma needs evacuation to prevent fibrosis and loss of cartilage from perichondritis. Evacuation can be accomplished through a standard laryngoscope. Suspension laryngoscopy allows more flexibility by affording two-handed manipulation within the larynx and repair of lacerations through the mouth. With time and voice rest, mild hematoma and discoloration will resolve without evacuation. The voice and airway generally will be satisfactory.

A Type 3 injury is a wound with laceration and displacement of cartilage. A Type 3 injury may be fatal before emergency treatment is available. If the patient survives, a tracheotomy probably will be in place before the injury is defined. Throughout repair, a tracheotomy through the second and third tracheal rings should be adequate; however, if the tracheotomy has been made higher, it should be lowered. Fractures can be approximated by direct wiring with stainless steel sutures, and mucosal lacerations should be sutured with absorbable material.

If mucosa is missing, a split-thickness skin graft that is held in place with a compressible intraluminal stent provides several benefits: (1) prevention of low-grade infection of cartilage by providing a living dressing; (2) prevention of granulations and excessive scarring with contracture; and (3) hastening of the healing process. A graft will shorten the time a stent is required in the lumen, in addition to being well tolerated and causing minimal difficulty after operation if a hair-free area is chosen as the donor site. A compressible stent (sponge rubber) is cut to size, and the skin graft with the raw surface turned outward is sewn around the stent. The stent and graft are set in place through the laryngeal wound and are secured with transfixion wire. Also, the stent should be held to the tracheotomy tube with a fishline suture that is passed the full length of the stent and back to the caudal end. In 10 to 14 days, the initial stent should be removed through the mouth—care being taken not to

avulse the portion of the skin graft that is adherent to the reconstructed laryngeal lumen.

The period of stenting must be based on the extent of the injury and the status of the lumen at the time the first stent is changed. A minimal stenting period of three weeks has provided satisfactory results; however, eight weeks or more may be required. The final result in a patient with a Type 3 injury is often less than perfect.

The goal of decannulation is obtained more often than that of a normal voice. If the vocal cords are paralyzed, further efforts toward glottic rehabilitation for voice improvement or enlarging the glottic airway should be delayed for six to 12 months to be certain that all possible function has returned. Paralysis of the bilateral abductor muscles in a patient with an inadequate airway can be improved by arytenoidectomy and lateral repositioning of one vocal cord. An abductor paralysis associated with glottic air loss and a weak voice often can be improved by injection of Teflon lateral to one vocal cord to approach glottic closure during phonation.

Summary

Traumatic injuries of the larynx and cervical trachea vary from minimal hematoma to complex fracture, dislocation, or separation. Optimal rehabilitation of the airway and voice will occur if the injury is recognized early and if a program of management consistent with basic surgical principles of wound repair is instituted. In a few patients, the severity of other injuries may be responsible for delayed treatment of the airway, but the therapeutic priorities and timing should be determined through consultation with a laryngologist.

In most patients, a good airway should be an approachable goal, but chances for a good voice are less favorable if injuries are severe. All members of the team involved in managing the accident victim, especially the residents and interns who staff the emergency room, should be aware of the hazards of an injury to the airway and the essentials of early treatment.

Myasthenia Gravis

GEORGE J. MOTSAY, M.D., K. VISUDH-AROM, M.D., LEONARD S. SCHULTZ, M.D.
AND RICHARD C. LILLEHEI, M.D., Ph.D.

Myasthenia gravis is a chronic disease characterized by a variable degree of muscle weakness following voluntary use. Most commonly involved are the extraocular and other muscles innervated by the cranial nerves. Characteristically, the illness has a tendency to exacerbations and spontaneous remissions. Although in most cases certain muscles have a continually reduced function, the outstanding feature of the weakness is its relationship to activity. The chief feature of a pathologically rapid exhaustion of muscle power, linked to an abnormal slower speed of recovery, defines myasthenia gravis as unlike any other neurological process.

In the majority of cases the clinical manifestations are gradual in onset, but the disease may be ushered in suddenly with a sensation of general weakness. Ptosis, unilateral or bilateral, due to weakness of the levator palpebrae and diplopia due to involvement of the extrinsic ocular muscles are the commonest early manifestations. The weakness in the ocular muscles may occur in almost all combinations of functional disturbance. The day-to-day variability in ocular phenomena is one of the most diagnostic features. Pupillary abnormalities are almost never present. Visual fields and acuity are not altered.

Myasthenia does not always manifest itself initially in the extraocular muscles, since certain patients may present with speech or swallowing difficulty or other muscle group deficits but the extraocular muscles are affected at some stage in almost every patient.

As the disease progresses other muscle groups are involved. The classic picture is presented by the patient with bilateral ptosis resulting in a sleepy appearance; orbicularis oculi weakness with inability to close the eyelids; facial diplegia, rendering the face expressionless and apathetic; weakness of the circumoral muscles giving rise to the myasthenia snarl; and weakness of the masseters resulting in the mouth being constantly open. The voice becomes hoarse, nasal and gradually less and less distinct and complete aphonia may develop. In the more severe cases, dyspnea is a distressing symptom resulting from involvement of the respiratory muscles.

Once the disease has appeared the course may follow several patterns. There may be gradual extension of the involved areas to a steady state of weakness or there may be rapid deterioration. In one series of 220 patients, 32 percent died of the disease from three months to 25 years after onset. Eighty-five percent of these deaths occurred within six years. Schwab[14,15,16] reports that 10 percent of the patients died within 10 years of the onset.

Upper respiratory infections, grippelike illnesses and emotional tension are associated with exacerbations of the disease. Worsening of the condition often occurs during the premenstrual or postpartum periods.

Etiology

In view of the frequency with which thymic abnormalities are present in myasthenia, and the postpartum and menstrual relationships, many observers have concluded that this disease is basically an endocrine disturbance. No consistent dysfunction of an endocrine nature has been demonstrated and treatment with various hormones, including cortisone and ACTH, has not been beneficial.

Evidence is increasing that the thymus has an immunologic function. Moreover, the occurrence of neonatal myasthenia in offspring of myasthenic mothers which spontaneously subsides about seven weeks after birth indicate that myasthenia gravis may be a unique type of autoimmune disease. This is supported by the following:

1. Wilson and associates have thymic extracts which act as neuromuscular blocking agents;
2. Muscle biopsy shows a collagenlike disease;
3. Patients with myasthenia gravis have elevated gamma globulins and one fraction has been shown to bind to muscle;
4. Serum from myasthenic patients will cause lysis of frog muscle cells;
5. Serum complement is high in exacerbations of myasthenia and low in remissions;

6. Myasthenia is associated with known autoimmune problems (rheumatoid arthritis, acrocyanosis and systemic lupus erythematosis).

With the development of suitable recording methods for motor nerve stimulation and muscle recording, evidence is accumulating that the defect in neuromuscular transmission in myasthenia is due to an alteration in the acetylcholine mechanism. This could result from:

1. failure of nerve impulse to release a normal quantum of acetylcholine;
2. an excessive concentration of cholinesterase at the neuromuscular junction; or
3. elevation of the excitatory threshold of the motor end plate.

Thus, although it is agreed that the myasthenic defect is one of diminished acetylcholine effect, its precise mechanism remains controversial.

Medical Management

Medical management relies mainly on the anticholinesterase compounds neostigmine, pyridostigmine, and ambenonium alone or in various combinations. The alkyl phosphates, diisopropylflourophosphate, ethylpyrophosphate, hexaethyltetraphosphate, and octamethylpyrophosphoramide, once used, have proved too hazardous for clinical use.

Surgery and History

Since myasthenia has provided such a satisfying meeting ground for the clinician, physiologist and pharmacologist, it would be well to examine the historical highlights of this disease. Rufus, the Ephesian, is credited with giving first reference to the thymus. Galen called it an organ of mystery and felt it served as a cushion between the sternum and great vessels. The first description of myasthenia gravis came in 1671 from Thomas Willis, and in 1879 and 1893, Erb and Goldfam provided us with their classical descriptions.

The disease process was named myasthenia gravis in 1895 by Jolly and in 1912 Sauerbruch performed the first thymectomy for myasthenia gravis, a treatment which was unfortunately forgotten for many years. The next important step came in 1920 when Loewi and Dale developed their chemical theory of junctional transmission and in 1934 Mary Walker, after hearing a lecture on anticholinesterase therapy for curare poisoning gave physostigmine to one of her myasthenia patients. Thus, began the medical therapy for this disease.

In 1935 Viets and Schwab described a diagnostic test for myasthenia using an anticholinesterase and in 1939 Alfred Blalock presented his notable account of removing a thymoma from a myasthenic who recovered without neuromuscular disease and thereupon revived Sauerbruch's operative procedure for myasthenic patients. In 1946 Keynes reported on 51 thymectomies for myasthenia. Since that time there has been a multiplicity of reports from large institutions with large series of patients condoning and condemning thymectomy for myasthenia gravis.

Westerberg et al. stated that thymectomy was not of great value or it would not be so difficult to determine whether or not it is useful. As late as 1962, Ferguson reported a series of 145 patients with a small number of operations. He concluded that "when one considers the natural tendency of myasthenic gravis to remit and relapse it is extremely difficult to assess the precise role of the thymus in the symptomatology of myasthenia and the potential value of thymectomy itself." Simpson, on the other hand, after analysing 404 cases feels thymectomy is indicated in almost every case of myasthenia.

That there should be some dispute concerning therapy for a disease with such protean manifestations as myasthenia is quite understandable. Furthermore, when comparisons are made among different reported series a uniform classification must be used in the tabulation of results. Also, one must compare patients of similar age range because operated groups generally include many young patients while the nonoperated groups contain more older patients.

Probably the most important criterion for comparison of thymectomy series is to differentiate patients with thymomas from those without. Most of the early reports from this country included thymomas. Myasthenia associated with a thymoma is a far more severe disease, than that associated with a thymus showing hyperplasia of the germinal centers or so-called "normal, but enlarged" thymus.

Simpson in 1958 reported on a group of myasthenic patients aged 16 to 35, without thymoma, and treated by thymectomy and anticholinesterases. His evaluation of the therapeutic result depended on a comparison of the pre- and postoperative state with respect to signs, symptoms, exercise tolerance and drug requirements. He classified the results as A, B, C, or D and care-

fully explained what each letter represented so that others could similarly classify their patients. He hoped that such a classification would lead to a unified body of data so that statistical confirmation of results could be done.

Simpson found that fewer women die of myasthenia gravis if their thymus is removed than would be expected if treated with neostigmine. Also, a higher proportion of operated patients were greatly improved. These differences are significant to the .05 level. The greatest improvement tended to occur in the youngest patients with the shortest preoperative courses. These differences, however, are not sufficiently marked to discount chance effects.

In females, preoperative severity of the myasthenia measured objectively by neostigmine requirements did not appear to be a significant factor in affecting the course of survivors; although those who died were those who tended to be on higher neostigmine doses. Similar trends were found in the male series, but none of the differences were of a magnitude to exclude chance. However, the fact that the course of males, after operation, was in the same direction as female suggests that males do benefit in the same way as females from thymectomy.

Simpson compared his results with those from the Mayo, Boston, and Baltimore series after he had reclassified their results into his A, B, C, or D system. He also omitted those patients with thymomas. By doing this he was able to show that there is general agreement on the mortality rate and extent of remission in these American series similar to his own. Although the American centers did not consider that males are significantly benefited by thymectomy, here again patients with thymoma were included in the thymectomized group.

With regard to age, the Mayo Clinic series agreed that the age of onset did not significantly affect the response to thymectomy. An unexpected finding from Simpson's results is that the deaths occurring despite thymectomy were in a group whose characteristic age of onset, age at operation and duration of symptoms were similar to those of the group deriving the most benefit from thymectomy. Of those who died, whether thymectomy carried out or not, it appears that the crucial period is from four to seven years after onset. These patients are most difficult to control with neostigmine. Simpson also stated that even though occasional relapses were noted it was common for improvement to be progressive for several years after operation. Despite all the data in Simpson's report, we still do not have all the criteria to allow us to predict the effect of thymectomy in the individual patient. Nonetheless, it is clear that thymectomy should be seriously considered in all cases in which myasthenia is not confined to the ocular muscles. When only the eyes are involved, Ferguson et al. have reported on 69 patients who for the most part did well on medical treatment.

Thymomas

In patients with thymomas, which comprise from 10 to 35 percent of myasthenic patients, depending on the series, the mortality rate is not lowered by thymectomy and regardless of the mode of treatment mortality is up to 80 percent in some series.

The mean age of onset for myasthenia with a known thymoma is about 40 years for males and females compared to 25 to 30 years for non-tumor patients. Keynes feels these tumor patients are harder to control medically and Simpson has shown that the neostigmine requirements in his group of thymomas was 25 to 50 percent higher than his non-tumor patients.

Both Boyd and Keynes stress that the margin between benignity and malignancy is very fine with thymomas and advocate aggressive surgical therapy for all thymomas thought to be resectable since histologic benign lesions often involve the pleura and pericardium. Keynes prefers preoperative radiation while Boyd uses postoperative radiation. Others use only radiation instead of thymectomy.

Preoperative Care

The exact dose of anticholinesterase required preoperatively should be determined accurately so that overdosage in the postoperative period is avoided. Deep breathing and coughing should be practiced before operation. Cigarette smoking should be stopped.

Postoperatively

A tracheostomy should be performed in the operating room in almost all patients. Care must be taken to avoid a cholinergic crisis from too much anticholinesterase with resultant excessive

pulmonary secretions, muscle weakness and respiratory insufficiency. Postoperatively, signs of cholinergic crisis are muscarinic effects associated with compensated respiratory function, whereas preoperatively muscle cramps, diarrhea, nausea, and vomiting preceed the respiratory difficulties. It is imperative that trained personnel observe these patients postoperatively to recognize the signs of respiratory insufficiency.

Summary

Myasthenia gravis is a chronic muscle disease of variable weakness characterized by rapid muscle exhaustion and slow recovery. Much evidence exists for an autoimmune etiology although other evidence points to a hormonal imbalance. Medical therapy consists of anticholinesterase administration while surgical therapy relies on thymectomy. Recent, more precise evaluation of patients indicates that males and females without thymoma respond to thymectomy. Myasthenic associated with thymoma is more severe and responds poorly to drugs and thymectomy.

Preoperative evaluation and preparation are essential for safe postoperative management. Care must be taken to avoid giving too much anticholinesterase because toxicity signs can be confused with signs of insufficient medication.

Special Article

Psychiatric Training in a Department of Obstetrics and Gynecology

IRVING BERNSTEIN, M.D.*

A PSYCHIATRIC teaching program in the Department of Obstetrics and Gynecology at the University of Minnesota has been in operation since 1951. The aim is to offer students and staff experience in the recognition and treatment of the psychosomatic problems that present to the practicing physician.

In an obstetrical-gynecological service the connection between feelings and complaints is easily demonstrated. The relationship is often evident between feelings of insecurity and dysmenorrhea,[1] feelings of rejection and nausea and vomiting of pregnancy,[2] inability to compete and hypochondriacal complaints,[3,4] anger and sexual incompatibility, depression and abdominal discomfort. Using obstetrical and gynecological patients for psychiatric teaching does not generate the anxiety in students that usually occurs upon their exposure to the psychiatric patients routinely presenting on an inpatient service in a medical school hospital. Hill states "Utilizing severely ill psychiatric patients to teach medical students is unwise."[5]

Instruction for medical students was accomplished through five to seven weekly one-hour seminars, participation in weekly grand rounds, and the provision of consultative service and psychiatric care on the obstetrical-gynecological service during an eight week clerkship.

To establish such an integrated program, a psychiatrist with an interest in teaching, who enjoys identification with the general practice of medicine, must be available. He should be able to handle both the negative and positive feelings about psychiatry which present in students and staff. Initially, the program was accepted with some reservation by John McKelvey, Chairman of the Department of Obstetrics and Gynecology. In the following years, over-acceptance and inability to satisfy requests for service became problems.

Psychiatry was shown to be similar to general medicine in that pathology was demonstrated, treatment affected and disposition made by a psychiatrist, usually without the assistance of ancillary services. Basic psychiatric skills were taught. All students, graduate or undergraduate, were expected to become adept in interviewing a patient in a manner that reduced anxiety and utilized the patient-doctor relationship to the utmost. The students were taught to be noncritical, noncensoring, and accepting of their patient's feelings, to accept resistance and set limits, and to give reassurance only when indicated.

The importance of establishment of a personality evaluation in every patient was emphasized. Students were taught the initial history should include information about the patient's past and current life situations, without the patient's feeling an irrelevant and intrusive psychiatric inquiry was being made. After the initial interview each patient was to be psychiatrically categorized as normal, neurotic, psychotic, psychopathic, or organic. The student was shown that the personality of the patient can greatly determine the effectiveness of the treatment of a disease process. This could be demonstrated vividly in the treatment of a pregnant diabetic, whether the patient was neurotic, psychotic, psychopathic or organic. Obsessive compulsive pregnant diabetics respond well to treatment; on the other hand, psychopathic pregnant diabetics respond poorly.

To emphasize the value of psychiatric expertise, symptoms had to be eradicated or alleviated. Effective management of nausea and vomiting of pregnancy, urinary retention following delivery, vulvar itching, impotence, infertility, frigidity, and generalized hypochondriasis impressed the staff and students, and encouraged them to become personally involved in treating patients with such symptoms.

Positive feelings toward psychiatry developed in the department staff and the majority of the students participating. Some of the students decided to become psychiatrists, and eventually did. A number of obstetricians reported a better understanding of their patients because of the

*Clinical Professor of Psychiatry and Clinical Professor of Obstetrics and Gynecology, University of Minnesota Medical School, Minneapolis. Also, Chief of Psychiatry, Mount Siani Hospital, Minneapolis.

psychiatric experience they obtained during their residency.

In 1969 the University of Minnesota Medical School instituted a dramatic change in its curriculum.[6] It was divided into three phases, A, B, and D. Phase A, consisting of three quarters, and Phase B, consisting of five quarters, constituted the core program. After completion of the core program, the student may graduate in either three or five quarters with an M.D. degree. Phase D is essentially elective.

It became possible to graduate from the Medical School with very little practical experience in psychiatry. In Phase A, a course in Behavioral Science is offered which consists of 60 hours, of which 30 hours is experimental psychology. All instruction is given by non-medical personnel—psychologists and sociologists. In Phase B, a 50-hour lecture course called *Behavior of Man* is offered under the direction of a psychiatrist. In 1971 an 18 hour course in Human Sexuality was added to the curriculum. This is the extent of the required psychiatric exposure at the University of Minnesota and thus some students will be able to complete medical school without examining and being involved with the treatment of a single identified psychiatric patient. Kaufman[7] deplores such deemphasizing of psychiatry in medical schools in a recent paper in the *American Journal of Psychiatry*.

With this curriculum modification, psychiatric teaching in the Department of Obstetrics and Gynecology had to change because much of the teaching became elective. Two courses are now offered. One consists of one to three students choosing to be assigned halftime or fulltime to the author in a preceptorship for a maximum of six weeks during Phase D. The other consists of a ten-hour lecture course called *Medical Aspects of Human Sexuality* which meets weekly during Phase B. The preceptor experience with the medical students has been stimulating for both students and teacher. The course in *Medical Aspects of Human Sexuality*, on the other hand, has been unsatisfactory for most of the students and the instructor, mainly because the students registered, thinking they had no responsibility to do anything for the course.

Most students who attended the lecture course and took the Phase D clinical elective came with the intention of learning the "tools of the trade," such as hypnosis, and did not want to be involved as much with obtaining scientific insights. These were the students having some interest in psychiatry. It is assumed the others were not as interested in psychiatry and thus, received less exposure to clinical psychiatry. In other words, those students who might be in most need of acquiring psychiatric skills were getting the least training.

It appears that the new curriculum in the University of Minnesota Medical School, with its lessened emphasis on the emotional aspects of illness, will result in less efficient care of both psychiatric and non-psychiatric patients and reduce the number of students choosing psychiatry as a specialty.

Meetings

Annual Spring Business and Scientific Meeting
Minnesota Society of Anesthesiologists
May 6, 1972—Sheraton Motor Inn
Bloomington, Minnesota
"Medical-Legal Aspects of Anesthesiology"

CALORIES / 1 Cup Prepared Soup*

Beef Broth	25	Vegetable	77
Consomme	33	Tomato	79
Chicken with Rice	49	Cream of Asparagus	80
Chicken Gumbo	55	Cream of Chicken	87
Chicken Noodle	62	Beef	99
Chicken Vegetable	68	Cream of Potato	105
Turkey Noodle	72	Cream of Mushroom	131
Vegetable Beef	75	Green Pea	131

In planning high or low calorie diets, Campbell's more than 50 different soups offer you a wide choice. And, most of Campbell's Soups contain a wide variety of ingredients that can serve as supplementary sources of many essential nutrients.

* From "Nutritive Composition of Campbell's Products" which gives values of important nutritive constituents of all Campbell's Products. For your copy, write to Campbell Soup Company, Dept. 536, Camden, New Jersey 08101.

There's a soup for almost every patient and diet ..for every meal and, it's made by Campbell

the 3 phases of Eve

All women are not equal in their endogenous hormonal output. And, while all oral contraceptives are fundamentally effective, they exhibit **differences in their activity levels and estrogen-progestogen ratios that affect different women differently**—in both short and long-term use. Some brands may be insufficient for the woman's needs or else may exceed them.

Searle offers a family of O.C. products that covers the range of women's needs to help you provide the right pill for the right woman at the right time.

Med. *22*:11-17, Jan. 1969.

the Ovulen phase

Most women* with a **balanced hormone profile and normal menses** do best on a middle-of-the-road pill that is neither estrogen dominant nor strongly progestogen dominant.

(*Typical clues—normal body build and breasts, feminine appearance, healthy skin and hair. Vaginal cytology slide—balanced "pink and blue.")

Some women having problems on other O.C.s might do well on Ovulen.

Ovulen has a distinctive hormonal balance that combines moderate estrogenic activity with a slight progestogen dominance. It has an excellent record of patient acceptance.

Ovulen®

Each white tablet contains: ethynodiol diacetate 1 mg./mestranol 0.1 mg.

SEARLE

For brief summary of prescribing information, see following page.

the Demulen phase

Many women* who secrete **more estrogen** than most do well on a pill with lower estrogen activity and an increased progestogen overbalance.

(*Typical clues—shorter, plumper, full-breasted, with glowing skin and no wrinkles. Vaginal cytology slide "pink.")

Some women with special conditions that may be aggravated by higher estrogen-activity products may do better on this ratio.

Demulen combines minimal estrogenic activity with a moderate ratio of progestogen overbalance. It is particularly well suited to the young when low-dose (activity) is preferred. Demulen offers little risk of the most potent progestogen side effects; early breakthrough bleeding is often transient.

Demulen®

Each white tablet contains: ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.
Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.
Both Ovulen and Demulen are available in 21- and 28-pill schedules.

the Enovid-E phase

Some women* who secrete **less estrogen** than most do best on a pill with a moderate estrogen overbalance.

(*Typical clues—oily complexion, acne, hirsutism, masculinity, flat chest. Vaginal cytology slide—"blue.")

Patients with estrogen deficiency may show:

premenopausal syndrome
early-cycle bleeding
scanty menses
intermittent depression
increased appetite
steady weight gain
vaginal candidiasis

Enovid-E not only provides increased estrogenic activity with low progestogen activity, but also contains the only progestogen that is not antiestrogenic. Therefore it offers less risk of high-dose progestogen side effects.

Enovid-E®

Each tablet contains: norethynodrel 2.5 mg./mestranol 0.1 mg.

Oral contraceptives are complex medications and, after reference to the prescribing information, should be prescribed with discriminating care.

for the 3 phases of Eve:

a family of O.C. products

Ovulen®

Each white tablet contains:
ethynodiol diacetate 1 mg./mestranol 0.1 mg.

Demulen®

Each white tablet contains:
ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.

Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.

Actions—Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note—Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication—Ovulen and Demulen are indicated for oral contraception.

Contraindications—Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings—The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain[1-3] leading to this conclusion, and one[4] in this country. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll[3] was about sevenfold, while Sartwell and associates[4] in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as nonusers. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations preexisting uterine fibromyomas may increase in size. Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. Any possible influence of prolonged Ovulen or Demulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Ovulen or Demulen therapy. The age of the patient constitutes no absolute limiting factor, although treatment with Ovulen or Demulen may mask the onset of the climacteric. The pathologist should be advised of Ovulen or Demulen therapy when relevant specimens are submitted. Susceptible women may experience an increase in blood pressure following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives—A statistically significant association has been demonstrated between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals and mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function: increased sulfobromophthalein retention and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T^3 uptake values; metyrapone test and pregnanediol determination.

The Patient with More than One Cancer

CANCER IS AN exceedingly common disease. As our population increases in longevity and hopefully the treatment of malignant disease becomes more successful, it is to be anticipated that an increasingly large proportion of luckless individuals will be stricken with two or more primary and independent malignant neoplasms.

In 1932 Warren and Gates[2] were able to collect only 1259 cases of multiple primary malignant neoplasms from the world literature. By 1966 this total had swelled to over 20,000. During a single decade of Mayo Clinic practice we counted 1909 patients with more than one histologically confirmed primary cancer including 50 cases with cancers primary to three different tissues, two cases with cancers primary to four different tissues, and one case with cancers primary to five different tissues.

As Doctor Spanos and associates* have indicated in earlier pages of this issue, there is a striking predilection to develop a second cancer in a tissue that has already given rise to neoplasia. This phenomenon is grossly evident in the very frequent multiplicity of cancers of the skin, the oral cavity, the large bowel, the urinary tract, and the vulva, vagina, and anus, as well as in the very common bilaterality of breast cancer. The tendency to multicentricity of epithelial malignant disease is perhaps best explained by the words of Willis: "In human as an experimental carcinogenesis the effective stimuli are applied, not to one cell or one small group of cells, but to a more or less extensive area of epithelial tissue. All of the epithelium in that area is acted upon similarly, though of course, usually not equally. Neoplasia will commence where stimuli have been maximal, but the neoplastic process will later be manifested by neighboring tissue that was subjected to the same original stimuli." From a practical standpoint carcinoma should be regarded as a disease of an entire tissue rather than a single tumefaction. In surgical treatment, the entire tissue should be excised if this can be accomplished without disabling functional or cosmetic impairment and without prohibitive surgical risk. If this cannot be done, the patient must then be impressed with the vital importance of frequent follow-up examinations.

With regard to multiple neoplasms of different tissues of origin, Doctor Spanos and his coworkers have judiciously refrained from joining into the statistical parlor games that are so frequently being played with multiple cancer data. In spite of the large number of retrospective studies replete with comparative age specific incidences, etc., it can be stated without fear of valid contradiction that there is no evidence that the patient who has developed cancer is any more likely, or indeed any less likely, to develop a second cancer in a different tissue than is the patient who has never had cancer at all.

Muscae Volitantes

MUSCAE VOLITANTES, flies flying or flies that fly, are the floating specks of various shapes and size that people see in their field of vision. A patient will say, "What is this tiny object which I see but can not look at, because when I look at it, it darts away?" Because these floaters seem to fly about, they are likened to flies. These "flies," flitting in one's field of vision, may be as annoying as the sticky walking flies which one encounters in warm countries such as the Middle East where flies will walk on the merchant's face in the bazaar and seem oblivious to the brushing hand of the busy bargainer.

Muscae volitantes are vitreous floaters which cast a shadow on the retina and move with each eye movement. The motion of the shadow cast by the floater has a quick component of one to two seconds and a slow return component of from 5 to 12 seconds, depending on the physical state of the vitreous. Vitreous floaters may be discovered suddenly by the patient and this discovery may be very alarming. When the patient realizes that this is not an insect or a hair or thread caught in his glasses frame but that this is something wrong with his eye, he may become quite concerned. In practically all instances these patients can be reassured and told that although annoying, the floater they see represents no serious eye pathology.

There is the occasional person, however, as pointed out by Robertson,* who does have a retinal tear which is related to the vitreous floater pathology. Along with the vitreous floater there frequently are light flashes, and these are a little more common when the vitreous floater is associated with a retinal tear than when there is no retinal tear. As pointed out by Robertson, retinal tears frequently lead to retinal detachment. For this reason all patients with vitreous floaters must be examined carefully, even though serious retinal pathology is found in only a very small percentage of cases.

Muscae volitantes are but one of several entopic phenomena associated with the ocular media. Any object in the ocular media situated anterior to the retina can be seen entopically if it has an optical density different from that of the optical media. Floating bodies near the fundus, especially if large, are easily seen and may be quite annoying. They are most easily seen when viewed against a white page or light sky. No special optical aid is needed to see this entopic phenomena. To observe opacities in the interior part of the eye, one must use an optical aid which in effect causes parallel rays of light to pass from the region of the opacity to the retina. The opacity in these parallel rays then casts a shadow on the retina which is seen by the patient. A simple method which is used to produce parallel rays of light passing from the front of the eye to the back of the eye is to place a pinhole .1 mm. in diameter or smaller in a piece of paper, and then place this pinhole at the anterior focal point of the eye (15.7 mm. anterior to the cornea). A bright light is viewed and a shadow of the opacity falls on the retina. This entopic field is bordered by the shadow of the pupillary border, and the size of the pupil and defects in the pupillary border can be studied. If the pinhole is moved closer to the cornea than the anterior focal point of the eye, the shadow of the opacity in the media is magnified. If the pinhole is moved farther from the eye than the anterior focal point, the shadow is minified. The most important entopic phenomena are (a) opacities in the tear layer, corneal surface, and cornea (b) lenticular opacities and (c) muscae volitantes.

The presence of visible particles in the eye has been noted in the very old medical literature. Dechales (1690) and de la Hire (1694) speculated about the nature of muscae volitantes of the vitreous body. Probably the most brilliant observer of the subjective phenomena of vision who ever lived was Johannes Evangelista Purkinje (1781-1865), professor of physiology at Breslou and later at Prague. Sir Stewart Duke-Elder points out that Purkinje's contributions came while he was working in the attic of his house, and ceased when he was presented with the first State Physiological Institute in the world in 1839. Duke-Elder remarks, "It is only rarely that the true spirit of science thrives in an atmosphere of luxury."

Urinary Tract Infections

THE PAPER BY John M. Matsen in the March 1972 issue* of MINNESOTA MEDICINE brings us a thorough review of diagnostic procedures and therapy for urinary tract infections as seen by an experienced clinical microbiologist. The importance of urinary infections is emphasized by the fact that by age 60 as many as 10% of women will have had at least one episode. There is also the very real danger that the infection may ascend from the urinary bladder to the kidney. The clinical diagnosis of lower urinary tract infections is quite simple, but the identification of pyelonephritis in bacteriuric patients is more difficult, often requiring pyelography and tests of renal tubular concentrating ability. Patients with recurrent urinary tract infections should also have a voiding cystourethrogram in order to detect any lesions obstructing the bladder neck with significant vesicoureteral reflux, which may require surgical relief.

The recognition of high grade bacteriuria has been made relatively easy in recent years by the quantitative culture of a midstream aliquot of urine obtained by cleancatch, a method which is particularly easy in males but also applicable to females after proper cleansing of the vulva. The urine specimen should be promptly divided into separate portions in clean containers for microscopy of centrifuged sediment and gram stain of unsedimented urine, as well as a sterile container for quantitative culture for aerobic bacteria. These tests are sensitive, economical and specific, if properly done. Identification of the common causative organism usually is quickly made if several selective agar media are used. Susceptibility to antibacterial drugs can be easily determined on most bacterial pathogens by the Kirby-Bauer disc method. The test is particularly helpful in selecting therapy for patients with recurrent bacteriuria.

Chemotherapy for bacterial cystitis should be specific for the causative organism and need only be continued for a few days. The clinical result should be followed by further quantitative urine cultures. One has available numerous effective therapeutic agents, perhaps the least costly is sulfasoxazole. The treatment of acute pyelonephritis is more difficult, because the patients are often quite ill, and the bacteriuria is frequently due to more resistant bacteria, especially in patients developing infections after instrumentation. The choice of chemotherapy must be made with the aid of susceptibility tests, renal function tests (serum creatinine) and appropriate history to elicit possible drug allergies.

The treatment of patients with recurrent bacteriuria and chronic pyelonephritis is often quite unsatisfactory. One may use methenamine salts with urine acidification to suppress bacteriuria over prolonged periods, but evidence is conflicting as to the ultimate efficacy of chemotherapy in preventing relapses in these cases.

Finally, the prostate gland has recently been receiving some well-deserved attention as a possible source of recurrent bacteriuria in adult men. Stamey and others have shown that the prostate is often poorly penetrated by antibiotics. The best penetration seems to be obtained with sulfasoxazole, erythromycin or one of the tetracyclines. Acute prostatitis usually responds more quickly to chemotherapy than does chronic prostatitis, which is often not associated with infection with the common aerobic bacterial pathogens.

Ischemic Electrocardiographic Changes with Reversion

To some degree, the practice of medicine is controlled by concepts of disease and habits of treatment which are the products of hearsay from one physician to another or in some instances based on data passed even from one generation to another. A striking example is the supposed benefits of prolonged bed rest in a variety of illnesses, benefits which, in the last decade, have not withstood a more critical examination.

It is a widely held concept that gallbladder disease is more common in patients with heart disease and that patients with heart disease and gallbladder disease are apt to derive striking benefit from cholecystectomy. There has been evidence, particularly from autopsy series and a variety of case reports, to support this concept. The evidence is reviewed at some length in an article by Dr. John Anderson published in the March issue of Minnesota Medicine.*

That there is some kind of specific relationship between biliary tract and coronary heart disease, is not, however, universally accepted. Forrester et al.[1] from the Peter Bent Brigham Hospital found no significant increase in the incidence of gallbladder disease among a group of patients with coronary artery disease diagnosed angiographically. Neither did they find that gallbladder diseases contributed to the appearance of angina pectoris or cholecystectomy relieved its occurrence. In a review of the literature up to 1969, Friedman[2] found evidence for any relationship at best "meagre." With regard to the ECG abnormalities, Birbaum and Braun[3] found the incidence in patients suffering from cholelithiasis no different from that in a control group.

The truth of the matter remains in doubt. More information is needed. There are obvious benefits to be obtained from cholecystectomy in patients with coronary artery and gallbladder disease. Not least of these is a relief from the diagnostic confusion as to whether, in any given instance, the patient is having a heart or a gallbladder attack. However, that such surgery contributes to the relief of angina, or somehow ameliorates progression of the heart disease is not certain. Recommendations for this particular operation should possibly receive no higher priority than would be given in any group of high risk patients.

University of Minnesota Urology Department

The urology department of the University of Minnesota has received a $225,000 grant from the National Institutes of Health. The three-year grant will be used to support a study of genitourinary neoplasms, especially cancer of the kidney.

Dr. Elwin Fraley, department chairman, received a $140,000 grant three years ago from the Royal A. and Olive W. Stone Memorial Fund of the Minnesota Medical Foundation to establish a cancer research program in the department of urology. Dr. Fraley explained that the NIH grant, the first such given to a urology department, would be used to combine basic and clinical research efforts.

The laboratory team includes Dr. Thomas Hakala, Dr. Arthur Elliot, Dr. Anthony Castro and Dr. Ricardo Gonzales.

Laryngeal Trauma

SEVERE TYPES of laryngeal injuries are occurring frequently. This is due mostly to automobile accidents, but a new cause is the snowmobile. In the car, the larynx is crushed between the steering wheel or dashboard and the hyperextended cervical spine which acts as a perfect anvil. With the increased use of snowmobiles comes an increasing number of mutilating injuries and deaths. Maxillofacial and laryngeal injuries are seen more frequently due to snowmobiles.

Although some minor soft tissue injuries can resolve spontaneously, the more severe injuries with fracture and disruption of contour almost always heal with a severe limitation of the airway and vocal function. It is difficult to differentiate between the minor soft tissue injuries and the more severe injuries without a direct laryngoscopic examination or even at times an open reduction of the larynx. It is critical as DeSanto and Brown* point out that this distinction is made early, because the results are vastly better with proper treatment at an early time. If a watch and wait attitude is developed, the larynx may heal in a way that can never be corrected adequately even with multiple procedures. The patient may need to wear a permanent tracheostomy and have very limited vocal function.

These types of injuries occur commonly in remote areas. Emergency measures including tracheotomy are performed, but because of the severity of other injuries, or inattention to the larynx, the laryngeal injury is overlooked. Subcutaneous emphysema, hoarseness, pain, dysphagia, airway obstruction, or irregularity of the laryngeal cartilages by palpation are clues that must be fully evaluated.

Treatment consists of reduction of fractures on injuries to restore normal anatomy and splinting over a stent or a tube much like an andotracheal tube that is left in place for two weeks or three months depending upon the severity of the injuries.

Curtin, Holinger, and Greeley[1] reported 82 cases of laryngeal fracture. All but two had cicatricial stenosis of the larynx by the time they were seen. Fitz-Hugh, Wallenborn, and McGovern,[2] however, reported 28 cases of which 25 were treated early. Of these patients, 16 had good airways and 14 good voices out of 24 completed cases.

Some of the patients of Curtin, Holinger, and Greeley were undoubtedly denied early treatment because of the severity of their other injuries. It is fair to speculate that many, however, were denied early treatment because of the fact that the attending medical personnel were unaware of the importance of early treatment.[3]

Letter to the Editor

Dear Editor:

I was interested in your recent article in MINNESOTA MEDICINE February 1972 edition—"How Do I Take Care Of My New Baby, Doctor"? by Dr. A. G. Miller.*

As a practicing dermatologist, I question just a little of Dr. Miller's advice regarding skin care. He mentions that hexachlorophene is a halogenated salicylanilide. This is untrue. Hexachlorophene is a chlorinated bisphenol, and though related, is not a member of the salicylanilide group. Furthermore, Ivory is suggested as a good soap for routine skin care of children on the grounds that is not as drying as the germicidal soaps. Though the germicidal soaps do tend to produce drying of the skin with prolonged use, Ivory soap is in fact one of the most drying soaps available, and even though "pure", it is probably not the most desirable soap for routine use. In general, superfatted soaps such as Basis, Oilatum, Petrophyllic, etc. are probably more ideal. Note is made by Dr. Miller of the possibility of photocontact dermatitis after the use of germicidal soaps. Though this is certainly a fact in adults, not one single case of photocontact dermatitis to the germicidal soaps has been reported in infancy.

"Nature's Still Life"

Dr. Donald C. Bell, internist, spends a great deal of time hiking with his family, and it is not unusual to find the Bell family spending their vacations in the beauty spots of the nation. The cover photograph was taken while the family was hiking in the Rocky Mountains National Park in north central Colorado. It was about mid-day when the family chanced upon this beautiful first sign of Spring.

Dr. Bell practices at the Fairview Hospital and the Metropolitan Medical Center in Minneapolis.

Meetings

Medical Seminar dealing with the adolescent patient, Saturday, April 15, 9 a.m. to 5 p.m. Fairview Hospital and St. Mary's, Minneapolis. $10 fee will include luncheon. Contact Dr. Dorothy Bernstein, Director of Adolescent Treatment Unit, Fairview Hospital. Open to all physicians. Students and residents are invited as guests at no fee but advance registration requested.

When a child is abandoned, somebody at least leaves it on a doorstep.

Once a man starts downhill, it doesn't take him long to reach bottom.

Four years ago, he wasn't much different from you.

Then somehow he lost his job. His wife left. His kids went off someplace. Life just fell apart.

Homeless, forgotten men like this are among the people in our town who need your help.

Poor people, sick people, disturbed people, old people are counting on you to help change their lives.

Give the United Way. Please.

If you don't do it, it won't get done.

The girth control pill

Tepanil® Ten-tab®

(continuous release form)

(diethylpropion hydrochloride, N.F.)

When girth gets out of control, TEPANIL can provide sound support for the weight control program you recommend. TEPANIL reduces the appetite—patients enjoy food but eat less. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation.

Contraindications: Concurrently with MAO inhibitors, in patients hypersensitive to this drug; in emotionally unstable patients susceptible to drug abuse.

Warning: Although generally safer than the amphetamines, use with great caution in patients with severe hypertension or severe cardiovascular disease. Do not use during first trimester of pregnancy unless potential benefits outweigh potential risks.

Adverse Reactions: Rarely severe enough to require discontinuation of therapy, unpleasant symptoms with diethylpropion hydrochloride have been reported to occur in relatively low incidence. As is characteristic of sympathomimetic agents, it may occasionally cause *CNS effects* such as insomnia, nervousness, dizziness, anxiety, and jitteriness. In contrast, CNS depression has been reported. In a few epileptics an increase in convulsive episodes has been reported. *Sympathomimetic cardiovascular effects* reported include ones such as tachycardia, precordial pain, arrhythmia, palpitation, and increased blood pressure. One published report described T-wave changes in the ECG of a healthy young male after ingestion of diethylpropion hydrochloride; this was an isolated experience, which has not been reported by others. *Allergic phenomena* reported include such conditions as rash, urticaria, ecchymosis, and erythema. *Gastraintestinal effects* such as diarrhea, constipation, nausea, vomiting, and abdominal discomfort have been reported. Specific reports on the hematopoietic system include two each of bone marrow depression, agranulocytosis, and leukopenia. A variety of miscellaneous adverse reactions have been reported by physicians. These include complaints such as dry mouth, headache, dyspnea, menstrual upset, hair loss, muscle pain, decreased libido, dysuria, and polyuria.

Convenience of two dosage forms: TEPANIL Ten-tab tablets. One 75 mg. tablet daily, swallowed whole, in midmorning (10 a.m.); TEPANIL. One 25 mg. tablet three times daily, one hour before meals. If desired, an additional tablet may be given in midevening to overcome night hunger. Use in children under 12 years of age is not recommended.

Painful night leg cramps...

unwelcome bedfellow for any patient– including those with arthritis, diabetes or PVD

- Prevents painful night leg cramps
- Permits restful sleep
- Provides simple convenient dosage — usually just one tablet at bedtime

Prescribing Informotion — Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nacturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriasclerasis and static foot deformities. **Controindications:** Quinamm is contraindicated in pregnancy because of its quinine content. **Precautions/Adverse Reactions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastraintestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

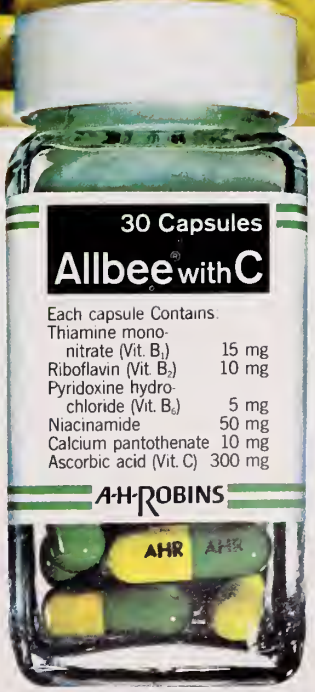
Quinamm

(quinine sulfate 260 mg., aminophylline 195 mg.)

Specific therapy for night leg cramps.



2 ways to provide a month's therapeutic supply of Vitamin C: 180 lemons or 30 Allbee® with C

As a source of ascorbic acid, the lemon really hits a high C (50 mg.). But your patient would still have to eat 180 lemons every month—6 a day—to get a therapeutic dose. And as the calypso singer puts it, "one hundred eighty lemons is impossible to eat." Fortunately, a bottle of 30 Allbee with C capsules (taken one capsule daily) supplies as much Vitamin C as all those lemons, plus full therapeutic amounts of the B-complex vitamins. For example, as much B_6 as two pounds of corn. Allbee with C is no lemon! This handy bottle of 30 capsules gives your patient a month's supply at a very reasonable cost. Also the economy size of 100. Available at pharmacies on your prescription or recommendation.

A. H. Robins Company, Richmond, Va. 23220

An Unusual Complication of Cystourethrography*

ALEXANDER S. CASS, M.D.† and ROGER VITKO, M.D.†

CYSTOURETHROGRAPHY HAS become an important procedure in the investigation of urinary tract infections in children and in the evaluation of upper urinary tract deterioration with myelomeningocele.

The following report shows that even a simple procedure can have complications.

Case Report

A 12-month-old male with a repaired lumbosacral myelomeningocele, had a cystogram (Figure 1) as part of a regular evaluation for the urinary tract complications of myelomeningocele.[1] The 8 Fr. soft plastic feeding tube, used as a catheter to introduce the dye into the bladder, could not be withdrawn from the urethra despite the use of reasonable traction. The child became markedly distressed and plain lateral radiography of the pelvis (Figure 2) revealed the tube to be doubled up in the urethra. Under general anesthesia the impacted doubled up tube was pushed back into the bladder and was then easily withdrawn through the urethra. The child voided normally when awake.

*Supported by the Medical Education & Research Account, Gillette Childrens Hospital.

†Urology Service, Gillette Childrens Hospital, St. Paul, Minn.

See page 324 for References 1-2.

Fig. 1—Cystogram showing the tube curved in the dome of the bladder, crossing itself at the bladder neck and its end engaged in the posterior urethra.

Fig. 2—Diagram showing tube doubled up in the urethra.

Discussion

Kjelberg reported two technical complications in 1,770 urethrocystographic examinations; an unduly soft catheter coiled up in the urethra requiring anesthesia for its removal and the tip of a many times sterilized catheter broke off in the bladder requiring operation for its removal.[2]

The cystogram radiograph (Figure 1) shows the tube curved in the dome of the bladder, crossing itself at the bladder neck and its end engaged in the posterior urethra. On withdrawal the tube remained doubled up and became impacted in the urethra in this position, with its lumen obstructed. An excessive length of the tube was introduced into the bladder and became bent with its end reentering the posterior urethra instead of coiling up in the bladder. This rare complication would have been avoided if the introduction of the tube into the bladder had stopped as soon as urine flowed through the catheter indicating that the end of the catheter had entered the cavity of the bladder.

Laboratory Letter

On Borderline Bilirubins

"A man's liver is his carburetor"
Anonymous

If a man's liver is his carburetor, then what he eats and drinks is his fuel mixture and the bilirubin he excretes is part of his exhaust fumes. Vary the mixture, and you vary the fume level.

A far-fetched metaphor? Not really. Consider two conditions that lead to borderline high bilirubins—alcohol ingestion and Gilbert's syndrome. The latter is a harmless familial disorder characterized by a persistent, but variable bilirubin rise often accompanied by vague gastrointestinal complaints.

If you flood your carburetor with alcohol, you're likely to foul your exhaust. Read our study of 500 alcoholics[1], and you'll find 198 of the 500, or nearly 40%, had high bilirubins. But the fumes were rarely pure bilirubin. Only eight patients had isolated high bilirubins; 190 had mixed in the exhaust other elevated abnormal tests—SGOT, alkaline phosphatase, uric acid, LDH, and total protein.

If you have only a borderline bilirubin, then, chances are small alcohol is causing your liver to sputter. The odds are probably greater you have a slightly defective carburetor—congenital hepatic dysfunction, or Gilbert's syndrome.

What is the incidence of this syndrome? Well, at Yale University Hospital, where liver profiles are routine, Levine and Klatskin reviewed 33,560 consecutive charts and found 601 patients with a total bilirubin of 1.5 mg% or greater with a direct fraction of less than 0.3 mg%[2]. Of these 601 patients, the authors classified 366, or one of the original 92, as having "unconjugated hyperbilirubinemia without overt hemolysis", another term for Gilbert's syndrome. This jibes with our experience. Of our last 1280 SMA-12/60 chemistry graphs, 14, or one of 91, had isolated total bilirubins of 1.5 mg% or greater.

So what does Gilbert's syndrome have to do with carburetor? As I mentioned you can think of the liver in the syndrome as a defective carburetor (actually it's probably a deficiency of hepatic glucuronyl transferase). The fuel mix and exhaust are important, too. If you limit the food intake in Gilbert's patients to less than 400 calories a day for 36 to 72 hours, the total bilirubin will abruptly rise two to three-fold, then fall back to its original level within 48 hours when you resume a normal diet[3]. Furthermore, the exhaust product in Gilbert's syndrome is usually pure bilirubin. Almost by definition, SGOT, LDH, and alkaline phosphatase are normal in this disorder.

The moral of the metaphor? If a borderline bilirubin causes you to suspect a congenitally defective carburetor, cut down the fuel and check the exhaust.

lonely than distrust?—George Eliot

Neurological Grand Rounds

Intracranial Abscess

PHYLLIS MELOFF, M.D.*

Localized suppurative lesions within the cranial cavity, which include epidural, subdural, occasionally subarachnoid and brain abscesses, have been recognized at least since 1773 when Richter reported finding pus posterior to an eroded frontal sinus in a 50-year-old man suffering from hemiparesis, aphasia and chronic sinusitis. Since the 1940s, antibiotics have supplemented surgical management of the disease. Yet, despite increasing knowledge of the disease process and improved therapy, difficulty with diagnosis persists, as does high morbidity and mortality. According to a recent review by Garfield[5] mortality is about 40 percent. Other authors[3,4] agree with this figure as an overall mortality rate but suggest that operative mortality, especially since the advent of penicillin therapy, is about 20 percent. However, Liske[7] compared pre-antibiotic and post-antibiotic mortality figures and found no appreciable difference; both were about 60 percent.

A study carried out between 1955-65 at the Minneapolis Veterans Administration Hospital by Gregory[2] indicated that the incidence of the disease did not change over this period. Others[4,5,7] confirm his results. A large urban general hospital may expect to see about five cases of intracranial abscess a year.

Incidence

Intracranial abscesses predominate in the first four decades of life with the highest incidence in the second decade.[3,7] A male preponderance of 2:1 is reported,[3,9] and Heineman[9] mentions an unexpected preponderance of whites, out of keeping with his center's high Negro population (Pittsburgh). Intracranial abscesses are related to infection in other parts of the body except for those which result from head trauma. The sites of original infection have changed little through the year.[3,9,6] Ear and mastoid infections are the most frequent source, followed roughly in order by paranasal sinus infections, metastatic infections from lung and pleura (including lung abscesses, bronchiectasis, emphysema), heart (endocarditis, frequently secondary to congenital heart disease), skin infections (usually of the face), infections following brain surgery and birth trauma. Head trauma and unknown sites each account for 10 percent of the cases.

Bacteriology

Bacteriological findings upon culture of pus obtained at surgery or autopsy from intracranial abscesses show streptococcus, pneumococcus or staphylococcus most often according to Brain[8] and the majority of other authors. Victor[6] notes that subacute bacterial endocarditis of the streptococcus viridans variety is rarely complicated by brain abscess, in contrast to acute bacterial endocarditis caused by staphylococcus aureus, beta hemolytic streptococcus and pneumococcus. The postulated reason for this is immunity of the central

*Neurology Service, Minneapolis Veterans Hospital.

nervous system (CNS) to chronic infection. This is in contrast to Heineman's[9] statement that the majority of abscesses are secondary to a focus of chronic suppuration which he believes accounts for the frequent finding of anaerobes such as bacteroides and streptococcus viridans. Authors reporting a high incidence of sterile cultures may be failing to perform careful anaerobic studies. Loeser[3] compared cases during periods of different therapeutic agents. He found more pneumococcus in the sulfa period from 1940-44, streptococcus viridans in the later 1940s (the penicillin period), and an increasing number of sterile cultures since introduction of broad-spectrum antibiotics. Liske[7] expressed a concern, not shared by others, that the use of antibiotics is creating resistant strains (e.g., streptococcus viridans) responsible for brain abscesses. A host of other organisms have been implicated with abscess formation including coliform bacilli, actinomyces and blastomyces, aspergillus, tuberculosis, cryptococcus, nocardia, coccidioides, candida, etc.

Pathogenesis

The pathogenesis of intracranial abscess is described by Victor[6] and Miller.[10] First, there may be *direct implantation* of organisms due to trauma. Second, there is the possibility of *direct extension* from a site of osteomyelitis (e.g., mastoid, frontal, sphenoidal) followed by local inflammation of dura with adherence to bone and subsequent penetration through meninges into underlying brain substance. Alternatively, this mechanism may give rise to subdural or epidural abscess or meningitis, or a combination of any of these; the factors involved in the choice of form not being understood. Third, and perhaps most frequent, is the process of extension of organisms *along tracts of intracranial veins* and sinuses. Thrombophlebitis of pial veins and dural sinuses block normal blood flow and lead to infarction of brain tissue, thus rendering it more suitable for growth of organisms. The spread along venous channels explains why abscesses are sometimes found far away from the original source of infection. Fourth, infective emboli or heart vegetations as well as septicemia may give rise to metastatic abscesses in an arterial distribution (usually the middle cerebral artery). Multiple abscesses are formed by this process in about 40 percent of cases.

Pathology

Pathologically a division is made by Gregory[2] into micro- and macroabscesses. Histologically, the former show occlusion of small vessels surrounded by clusters of bacteria, necrosis of vessel walls, perivascular infiltration of leukocytes with fibroblastic reaction or destruction of neurons. The latter comprise a gross focal collection of pus with or without a capsule.

Sequence

The sequence of events[6] in gross abscess includes the formation of an inflammatory exudate, mostly leukocytes surrounding blood vessels followed by necrosis of brain with the center of the lesion occupied by a mixture of organisms, necrotic brain and white blood cells, and surrounded by edematous parenchyma, macrophages, glial cells and many small leukocytes (cuffed veins). This is sometimes referred to as cerebritis. The intensity of reaction soon subsides, and a wall of granulation tissue forms around the pus. More chronically collagenous connective tissue replaces granulation tissue, but evidence of infection outside the capsule is

still found. In addition, the capsule is known to be of varying thickness. It is possible for encapsulated abscesses to continue invasion into white matter and become multilocular or rupture into the ventricles with catastrophic results.

Location

Abscesses can localize anywhere in the brain, but they predominate in the frontal and temporal lobes.[2,5] Parietal and subdural foci are also common and multiple foci vary from 5 to 48 percent in different studies.[4,5,7] In general, mastoid infections lead to abscesses in the middle cerebrum, temporal lobe or cerebellum (more commonly in children than adults by 3:2); sinus infections lead to abscesses in the anterior cerebrum, and metastatic abscesses often localize in the distribution of the middle cerebral artery. Basal ganglia, thalamus and brain stem are rare sites for gross abscesses, although microabscesses were not uncommon in these sites in Gregory's[2] study.

The incubation period for the disease in Loeser's[3] study was less than two months in over 50 percent, from two months to one year in 15 percent, and from six months to 20 years in 25 percent of cases.

Clinical Manifestations

Symptoms

Symptoms vary depending upon the location of the abscess. The most frequent symptom described is headache[2,6,10] often unilateral; followed in rough order of frequency by fever, drowsiness, confusion, personality change, focal seizures, nausea and vomiting, focal motor, sensory and speech disorders.

Signs

According to Loeser,[3] neurological signs on initial examination ranked in order of frequency as fellows: hemiparesis, hemiplegia, central facial palsy—60 percent; papilledema—50 percent; aphasia—25 percent; convulsions—20 percent; hemisensory deficit—18 percent. Cerebellar and Parkinsonian signs were far less frequent. Other physical signs included: ear infection and tender sinus—30 percent; heart murmur, cyanosis, clubbing—30 percent; temperature—40 percent (one-half had signs of meningitis); pulse 60—10 percent due to increased intracranial pressure.

Laboratory Tests

White blood count was elevated in 70 percent, sedimentation rate was increased in 80 percent. The spinal fluid showed 20 to 99 cells or less than five cells in the majority of cases. The protein was elevated. Sugar was not usually diminished unless suppurative meningitis coexisted. Organisms were absent except with concomitant meningitis.

Roentgenologic Studies

Xrays revealed a normal skull series in 50 percent. Others showed increased intracranial pressure. Sinus xrays revealed infection in 20 percent.

Contrast procedures were of localizing value as follows: ventriculogram localized the lesion in 50 to 84 percent; arteriogram localized the lesion in 10 to 73 percent; and pneumoencephalogram localized the lesion in 3 to 5 percent.

The arteriogram may be of value in distinguishing epidural and subdural

abscesses from each other and from brain abscesses. The former two initially resemble hematoma in early stages with downward displacement of cortical arteries, veins and sinuses. The brain scan, although not widely used in the studies heretofore reported, have proved of considerable localizing value.[2]

The electroencephalogram is valuable in localizing up to 60 percent of abscesses and characteristically shows focal delta activity in the involved area.

Differential Diagnosis

Intracranial abscesses usually run a rapid, progressive course but may be slow and mimic neoplasm. The differential diagnosis includes meningitis, cerebral thrombophlebitis, acute necrotizing hemorrhagic encephalopathy, primary and metastatic neoplasms, especially metastatic meningeal carcinomatosis, and massive ischemic infarction.[6,10] Some points in differential diagnosis include: high remittent fever in thrombophlebitis and subdural abscess, more frequent bradycardia with subdural abscess, focal signs more common in brain abscesses than in meningitis, with the reverse being true of meningeal signs, tenderness to palpation over affected area with extradural abscess, less frequent headaches with cerebral infarcts, slower progression of symptoms in tumors, and red cells in the cerebrospinal fluid with acute necrotizing hemorrhagic encephalopathy. A careful history is the most important diagnostic aid although present day antibiotic treatment for original sources of infection may delay the onset of symptoms of abscess from the initial infection, making diagnosis difficult.

Therapy

Therapy for intracranial abscesses is ultimately surgical with the exception of extradural abscess which may at times respond successfully to antibiotics alone.[10] Surgical therapy includes aspiration, drainage, packing and excision. Miller[10] pointed out that multiple abscesses may be missed on aspiration. On the other hand, excision carries the hazard of adding to the neurologic deficit as noted by Jooma and Pennybacker.[4] In general, excision is thought to carry a lesser mortality than aspiration, about 20 percent compared to 40 percent. Loeser[3] reports a 22 percent mortality with aspiration plus a combination of penicillin, sulfa and broadspectrum antibiotics as compared to 41 percent with aspiration and sulfa alone. Jooma[4] reports a 27 percent mortality with penicillin and 53 percent without penicillin. The site of abscess has little influence on mortality figures. Apart from danger to life, sequelae of abscesses include hemiparesis, aphasia, seizures (most commonly) and recurrence of abscess, which occurred in eight percent of Jooma's cases treated with aspiration or drainage.

Early Procedures

Garfield[5] suggests that the following course of management will lower mortality. As soon as a diagnosis of brain abscess is suspected, the patient should be transferred to a neurosurgical ward but lumbar puncture should not be performed because of the real risk of herniation owing to increased intracranial pressure.

Patients should be started on 4 million units of penicillin every six hours. Xrays of skull and chest and thorough otolaryngological exploration should be done. An electroencephalogram is of value if the patient's condition permits and time allows.

The State of Consciousness

Fully alert patients should continue on penicillin and have a brain scan within 48 hours. If the scan is negative, patients should be treated expectantly with antibiotics. Drowsy patients should receive penicillin and Mannitol (or Decadron) and have a brain scan within 24 hours. If a brain scan cannot be done and the site of obvious ear-nose-throat sepsis is found, appropriate burr-hole with aspiration should be performed. Thorotrast or pantopaque may be instilled into the abscess cavity so that the shrinkage may be followed radiographically. Angiography or a ventriculogram is indicated to identify the site of an acute non-encapsulated abscess. Unconscious patients should have penicillin and immediate Mannitol (or Decadron) and burr-hole with aspiration for obvious ear-nose-throat sepsis. A delay of up to three hours for brain scan is justifiable, but if it cannot be done in that time, a ventriculogram should be performed instead.

Conclusion

Garfield[5] emphasizes the haste required in diagnosis and treatment of this condition and places less emphasis on the specific surgical method as being decisive in determining the outcome.

G OR VK. JUST MAKE SURE IT'S PFIZERPEN.

When one out of 20 employees in America—including executives—has alcoholism, it's time for some plain talk about alcoholism. The alcoholic's family, friends and employer may mean well, but the silent treatment is no way to treat a disease. And alcoholism is a disease from which recovery is possible, rather than a moral weakness for which the alcoholic should be pitied—or fired. It's a disease which ranks with heart disease, cancer and severe mental disorders as a public health menace.

The National Council on Alcoholism has pioneered in setting up joint union-management alcoholism programs. In these programs, industry is achieving *recovery rates averaging 60 to 70 percent*. Management profits by retaining its experienced employees and regaining lost productivity—estimated at six billion dollars. Unions profit by increasing health and welfare protection for members and keeping them in the active work force.

If you think alcoholism is affecting your business, **talk it over with the Director of Labor Management Services, National Council on Alcoholism, 2 Park Avenue, New York, N.Y. 10016.**

National Council on Alcoholism inc.

140/90 is normal blood pressure...or is it?

An extensive study based on nearly 4 million life insurance policies suggests that a blood pressure reading of 140/90 requires close medical supervision.

Study Findings. Twelve years ago the Society of Actuaries reported on an extensive study based on the lives and deaths represented by almost 4 million life insurance policies. From this vast survey—"The Build and Blood Pressure Study"[1]—insurance experts concluded that:

- Blood pressure above 140/90 is accompanied by increased morbidity and requires close medical attention.
- Even small increments in either systolic or diastolic blood pressure progressively and steeply shorten life expectancy.

Other Studies. Studies conducted with large numbers of patients since that time have echoed the above findings. Two studies published in 1970—the VA Cooperative Study Group on "Effects of Treatment on Morbidity in Hypertension"[2] and the "Framingham Study"[3]—suggest that treatment of even mild hypertension may, over time, offer significant benefits to the patient.

Another Point of View. Although a growing body of studies suggests that treatment of mild hypertension is warranted, medical opinion is not unanimous. Some clinicians recommend that drug treatment for mild hypertension be reserved for patients with additional risk factors such as smoking, high cholesterol levels, heart or kidney involvement, or a family history of vascular disease. Dr. Walter M. Kirkendall stated this position in his recent paper "What's With Hypertension These Days?"[4] Discussing the management of hypertension in patients with a sustained diastolic pressure up to 100 mm Hg, he said: "Generally, I do not recommend antihypertensive therapy unless patient's blood pressure approaches the upper limit for the group and a number of adverse factors exist, such as male sex, family history of vascular disease, youth, evidence of heart or kidney involvement."

Drug Therapy for Hypertension. Although opinion varies on when to start drug therapy for mild hypertension, many physicians agree that treatment should start with a thiazide diuretic such as HydroDIURIL. For the adult patient, the usual starting dosage is 50 mg b.i.d. Dosage adjustments are recommended as the patient responds to treatment. The patient whose therapy begins with HydroDIURIL frequently can continue to benefit from it, because HydroDIURIL usually maintains its antihypertensive effect even when therapy is prolonged.

25- and 50-mg tablets

HydroDIURIL®

(Hydrochlorothiazide|MSD)

Therapy to Start With

Drug Therapy for Hypertension. Although opinion varies on when to start drug therapy for mild hypertension, many physicians agree that treatment should start with a thiazide diuretic such as HydroDIURIL. For the adult patient, the usual starting dosage is 50 mg b.i.d. Dosage adjustments are recommended as the patient responds to treatment. The patient whose therapy begins with HydroDIURIL frequently can continue to benefit from it, because HydroDIURIL usually maintains its antihypertensive effect even when therapy is prolonged.

CONTRAINDICATIONS: Anuria; increasing azotemia and oliguria during treatment of severe progressive renal disease. Known sensitivity to this compound. Nursing mothers; if use of drug is deemed essential, patient should stop nursing.

WARNINGS: May precipitate or increase azotemia. Use special caution in impaired renal function to avoid cumulative or toxic effects. Minor alterations of fluid and electrolyte balance may precipitate coma in hepatic cirrhosis.

When used with other antihypertensive drugs, careful observation for changes in blood pressure must be made, especially during initial therapy. Dosage of other antihypertensive agents, especially ganglion blockers, must be reduced by at least 50% because HydroDIURIL potentiates their action.

Stenosis and ulceration of the small bowel causing obstruction, hemorrhage, and perforation have been reported with the use of enteric-coated potassium tablets, either alone or with nonenteric-coated thiazides. Surgery was frequently required, and deaths have occurred. Such formulations should be used only when indicated and when dietary supplementation is impractical. Discontinue immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occurs.

Thiazides cross placenta and appear in cord blood. In women of childbearing age, potential benefits must be weighed against possible hazards to fetus, such as fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult.

The possibility of sensitivity reactions should be considered in patients with a history of allergy or bronchial asthma. The possibility of exacerbation or activation of systemic lupus erythematosus has been reported for sulfonamide derivatives, including thiazides.

PRECAUTIONS: Check for signs of fluid and electrolyte imbalance, particularly if vomiting is excessive or patient is receiving parenteral fluids. Warning signs, irrespective of cause, are dryness of mouth, thirst, weakness, lethargy, drowsiness, restlessness, muscle pains or cramps, muscular fatigue, hypotension, oliguria, tachycardia, and gastrointestinal disturbances. Hypokalemia may develop (especially with brisk diuresis) in severe cirrhosis; with concomitant steroid or ACTH therapy; or with inadequate electrolyte intake. Digitalis therapy may exaggerate metabolic effects of hypokalemia, especially with reference to myocardial activity. Hypokalemia may be avoided o treated by use of potassium chloride or giving food with a high potassium content. Similarly, any chlorid deficit may be corrected by use of ammonium chlorid (except in patients with hepatic disease) and largel prevented by a near normal salt intake. Hypochloremi alkalosis occurs infrequently and is rarely severe. I severely edematous patients with congestive failure o renal disease, a low salt syndrome may occur if dietar salt is unduly restricted, especially during hot weathe

Thiazides may increase responsiveness to tubocu rarine. The antihypertensive effect of the drug may b enhanced in the postsympathectomy patient. Arteri responsiveness to norepinephrine is decreased, neces sitating care in surgical patients. Discontinue drug 4 hours before elective surgery. Orthostatic hypotensio may occur and may be potentiated by alcohol, barbi urates, or narcotics.

Pathological changes in the parathyroid glands wit hypercalcemia and hypophosphatemia have been see in a few patients on prolonged thiazide therapy. Th effect of discontinuing thiazide therapy on serum ca cium and phosphorus levels may be helpful in asses ing the need for parathyroid surgery in such patient Parathyroidectomy has elicited subjective clinical im provement in most patients, but has no effect c hypertension. Thiazide therapy may be resumed aft surgery.

Use cautiously in hyperuricemic or gouty patient gout may be precipitated. May affect insulin requir ments in diabetics; may induce hyperglycemia ar glycosuria in latent diabetics.

ADVERSE REACTIONS: Rare reactions inclu thrombocytopenia, leukopenia, agranulocytosis, apla tic anemia, cholestasis, and pericholangiolitic hepatit Nausea, vomiting, diarrhea, dizziness, vertigo, pare thesias, transient blurred vision, sialadenitis, purpu rash, urticaria, photosensitivity, or other hypersen tivity reactions may occur. Cutaneous vasculitis p cipitated by thiazide diuretics has been reported elderly patients on repeated and continuing exposu to several drugs. Scattered reports have link thiazides to pancreatitis, xanthopsia, neonatal thro bocytopenia, and neonatal jaundice. When adve reactions are moderate or severe, the dosage thiazides should be reduced or therapy withdrav

Perinatal

The Perinatal Care Center

MARTHA J. BURKE-STRICKLAND, M.D. and DONALD W. FREEMAN, M.D.

WIDESPREAD INTEREST is beginning to develop in perinatal care centers whose broad purpose is to improve perinatal care.[1,2,3] These centers involve the combined efforts of physicians and other health workers concerned particularly with obstetrics, pediatrics and anesthesia. Ideal care of the sick newborn begins before his birth with recognition of a high-risk situation in pregnancy. Intensive care during the remainder of that pregnancy and during labor and delivery and the uninterrupted continuation of special care in the newborn intensive care unit should be followed by health-maintenance care until the needs of both the mother and the infant can be met by other community facilities. Perinatal centers are designed to provide such care.

The development of such a perinatal center at HCGH started when a high-risk problem obstetrics outpatient clinic began functioning at Hennepin County General Hospital (HCGH) four years ago. Amnioscopy and fetal blood sampling techniques for detecting fetal distress were introduced about the same time. In 1969, the obstetrical service began exploring electronic monitoring of the fetal heart rate and intrauterine pressures. Concomitantly the pediatric service began putting together a newborn intensive care unit (NICU). The follow-up high risk infant clinic was opened in 1970.

Mutual discussion and review at biweekly meetings of the obstetric, pediatric and often the anesthesia staffs have brought increasing awareness of problems as well as solutions to some of the problems. This interdepartmental cooperation has been the focal point in the translation of the perinatal care center concept into a functioning continuum of service at HCGH.

Since HCGH serves a population with an increased incidence of high-risk pregnancies and as a teaching hospital has the reservoir of skilled personnel necessary to staff such a program, it is appropriate that HCGH should be one of the pioneers of this approach in the State of Minnesota. Since these changes do carry a price tag and come at a time when all medical costs are under critical scrutiny, it is reasonable to ask: Does the program make any real difference?

Comparing earlier statistics of the program with later phases suggests that the entire program is beginning to have significant measurable results. For example the total perinatal mortality rate decreased from 45 per 1,000 live births in 1969, to 23.6 in 1971. The percentage of patients with high-risk situations remains high and has been generally without significant change in the three year period. Fourteen percent of the babies born at HCGH are in the low birth weight category (500-2,500 grams), premature rupture of membranes occurs in 16%, hypertensive toxemia in 8% and intravenous oxytocin is needed for induction of labor or treatment of abnormal labor patterns in 17%.

Since the pathogenesis of neonatal Respiratory Distress Syndrome (RDS) appears to be related to hypoxic stress of the fetus and the newborn, the incidence and survival of newborns with RDS

TABLE
Data From Hennepin County General Hospital Perinatal Care Program

	1969	1970	1971
Fetal Death Rate*	16.2	14.0	10.5
Newborn Death Rate*	29	16.2	13.2
Perinatal Death Rate*	45	30.5	23.6
Prematurity Rate	14.5%	15.2%	13 %
Premature Death Rate*	18.4%	11 %	9.2%
Incidence of RDS*	(36.5)†	36	21
Survival of RDS	(46 %)†	70 %	56 %

* Per 1,000 live births at HCGH.
† Close estimate; uniformity in recording data not established.

may be used as another indicator of the effectiveness of management of the newborn.[4] Monitoring the fetus during labor and delivery permits manipulative intervention on behalf of the fetus as well as anticipatory treatment of shock when present in the infant at birth. During the last half of 1971, such monitoring became feasible for nearly all the labors that needed it. Seventeen percent of all labors are now electronically monitored. The pediatric team is alerted whenever signs of stress are detected in the fetus and is on hand in the delivery room to assist in care of the baby. With no change in criteria for making the diagnosis, the incidence of RDS among babies born at HCGH dropped from 36 per 1,000 live births in 1969 and 1970, to 21 per 1,000 live births in 1971.

The survival rate of infants with RDS decreased to 56% in 1971, after a very satisfactory 70% survival in 1970. Analysis of contributing factors gives hope for a better future and a cogent argument for the idea that an intensive care unit must be properly staffed and equipped if it is to make a difference.

As the newborn intensive care service developed at HCGH, the demands rapidly exceeded the capacity of the unit. During the first few months of 1971, the unit operated in temporary makeshift quarters. An appalling death rate in the unit during January and February made it clear that it was no favor to anyone to operate in such a fashion. Time studies confirmed the staff-patient ratios needed to render different levels of care in the unit. It was agreed to follow established guidelines even if some babies born at HCGH had to be transferred to other special care units. This would permit the staff to give real intensive care. The difference in RDS mortality during the two periods of 1971 is striking. Eight of ten cases died during January and February with a survival of only 20%. The figures reversed for the rest of the year with a survival of 70%. The eight deaths of 27 cases in that period included one infant who was transferred and died in another unit.

To this point only numbers salvaged have been presented. Assessment of the quality of life thus preserved is more difficult. Accumulation of long-term data on many variables is needed for definitive answers; however, preliminary reports are encouraging. For example, though the percentage of babies delivered by cesarean section who come to the NICU has not changed significantly, the average length of stay in the unit has decreased from 15.5 days to eight days. Of 29 infants who required respirator assistance for survival and who have been followed for at least eight months after discharge from the unit, only five, or 17%, have severe neurological handicaps. This means that 24 infants who would not have survived at all in the traditional care setting have survived with intensive care as reasonably intact individuals who should be able to function effectively in society. In all 17 infants who have survived oxygen therapy with residual bronchopulmonary dysplasia, x-ray follow-up for six to 18 months showed that gradual architectural restoration of the lung is occurring. The incidence of recurrent pulmonary infections requiring rehospitalization for these infants has been reduced by instituting a home program of nebulization and physiotherapy.

An improved system for data collection and retrieval is underway for 1972. This should provide more of the long-term answers desired as well as help to focus attention on areas that need improvement. In the meantime, indications seem to be that coordinated intensive perinatal care does make a difference at HCGH.

Review

Laparoscopic Sterilization

STEPHEN L. LARSON, M.D.*

USE OF THE LAPAROSCOPE for female sterilization has gained favor in recent years. The procedure was first suggested by Anderson[1] and by Power and Barnes[2] about thirty years ago. However, Palmer[3] of France, Steptoe[4] of Britain and Frangenheim[5] of Germany first performed such sterilizations in the early 1960's. Within the last four years, many American investigators have found the procedure useful.

Technique

The procedure of laparoscopy is performed in the usual fashion.[3] Usually no preoperative enema, catheterization or shaving is required. The operation can be done on the day of admission to the hospital. In brief, the tubal sterilization is accomplished as follows. Under laparoscopic control, the isthmic area of the uterine tube is grasped with a tong, biopsy forceps or grasping forceps. When a moderate coagulation current is applied, the tube can be seen to blanch in a radial fashion for 1 to 2 cm. in either direction and into the mesosalpinx. The operator often will feel a popping sensation as the isthmic region is coagulated. Some authors[6,7,8,9] advocate that the tubes not be transected to prevent tubal fistulae. However, others describe division of the tube through the coagulated area, with or without removal of a segment for biopsy. This is accomplished with ease and with no bleeding. With rare exception, the patient may be discharged within 24 hours after surgery.

Outpatient sterilization using the laparoscope has been employed to reduce hospitalization and procedure costs. The patient is admitted the morning of surgery, after fasting. Wheeless[10] was able to discharge 73 of 75 patients at eight hours after surgery. There were no postoperative complications in this group. Steptoe frequently discharged his patients after nine hours.[11] Peterson and Behrman[12] believe that patients can be safely discharged eight hours after laparoscopy if the vital signs were stable. If bleeding occurs, it is found at operation or in the immediate postoperative period. Suction curettage for induced abortion, in combination with laparoscopic sterilization, may be done on an outpatient basis.[13]

Postoperative Hysterosalpingography

Opinions differ regarding the role of postoperative hysterosalpingograms. Liston et al.[7] found the procedure useful and discovered two failures and two tuboperitoneal fistulae among 78 patients having hysterograms. They, therefore, recommend tubal electrocoagulation without transection as the sterilization procedure of choice. Wheeless[14] used hysterosalpingography to identify the patients with fistula for possible reoperation. Peterson and Behrman[12] abandoned the procedure for fear that the hydrostatic pressure applied would open the medial stump on the transected tube and thereby favor future ectopic or uterine pregnancy. Steptoe[15] has also discarded this procedure because the only two pregnancies among 1350 patients followed salpingograms that produced fistulae. Other authors described cases in which flow of the radiopaque dye from the medial end of a transected tube was observed, but subsequent laparoscopy demonstrated tubal occlusion.[7,16] Jordan et al.[9] demonstrated that methylene blue injection at the time of operation was of no value, because postoperative fibrosis is necessary for the desired effect of tubal occlusion. Their hysterosalpingograms showed this process to be incomplete at six weeks. By 12 to 16 weeks after sterilization, fibrosis was complete. In summary, follow-up hysterosalpingography is useful to detect tuboperitoneal fistulae or technical failure (cautery of the round ligament or of the utero-ovarian ligament) but there probably is a substantial risk of the procedure forcing open the sealed medial end of the uterine tube.

Combined With Induced Abortion

In some instances therapeutic abortion has been performed at the time of laparoscopic sterilization. Steptoe and Imran[13] described 101 such cases with an average postoperative hospitaliza-

*Minneapolis, Minnesota.

tion of 2.4 days. Some, however, returned home nine hours after surgery. At the time of laparoscopy, they inspected the uterus for effective contractions and for possible perforation. They emphasized great care in handling the uterine tubes during pregnancy to avoid traumatic bleeding. One of these patients underwent laparotomy for bleeding, another developed a pelvic abscess and required antibiotics for a low grade fever. Steptoe's total series of combined operations has been increased to 189.[15] Fifty-six additional instances of the combined procedure have been noted in the literature.[7,8,12,17]

Postpartum

Keith et al.[18] have found sterilization by laparoscopy to be useful in the postpartum period. The procedure was done as late as the sixth postpartum day among 44 patients. Uterine trauma occurred in "several" patients from the instrumentation. In addition, three patients were explored (one for bleeding), one patient herniated omentum through the abdominal incision, and nine patients experienced anesthetic complications. Steptoe has used this technique in 61 patients without problem.[15] Siegler[19] has stated that this method is not the procedure of choice for postpartum tubal ligation, and other authors[20] believe that it does not compete with the standard technique of postpartum sterilization. The lack of reported cases of this variation of laparoscopic sterilization may indicate its lack of popularity.

Failures

Pregnancies that follow laparoscopic sterilization must be divided into operator failures and procedure failures of nine pregnancies reported after 760 sterilizations by Liston,[7] five patients were in the luteal phase of the cycle at the time of laparoscopy and were unknowingly pregnant. One of these patients maintained the pregnancy despite a curettage at laparoscopy. Two others had electrocoagulation of the round ligament and, in another patient, "the operator seemed to have omitted to deal with one appendage." The ninth patient was a true procedure failure with an ectopic pregnancy after tubal diathermy and division, verified by hysterosalpingogram and proved at laparotomy. Eight authors reported a total of 3,658 laparoscopic sterilizations with five true failures (Table). These failures may be compared to the overall failure rate of 1 in 140 procedures, calculated by Garb[21] from 30,000 tubal ligations reported in 46 articles. Among 5,477 Pomeroy procedures, he found that one in 250 had failed.

Restoration of fertility is theoretically possible after laparoscopic sterilization.[20] Donald[22] uses a scissor technique for tubal transection without biopsy and the utero-ovarian arterial anastomosis is not incised. The distal portion of the tube may be reimplanted at a later date. There are no reports of a successful reimplantation.

Complications

Complications of the procedure are infrequent. None have been reported among 108 procedures by three authors.[16,17,23] The larger series of sterilized patients have required laparotomy in about one of 200 procedures. Nine authors with fifty or more patients and with complications stated had a total of 3,702 procedures. Sixteen patients had laparotomy for bleeding that could not be stopped under laparoscopic control. In a preliminary report from Johns Hopkins[24] eight of 800 patients were explored, most of them for bleeding. Because the majority of the complications occurred with the first 200 patients, lack of experience may play an important role. The tearing or shearing action of the tong may con-

TABLE

TOTAL	3658	5	6	9

*Incomplete tubal transection found at laparotomy.

tribute to bleeding from the mesosalpinx,[12,25] if the operator does not use the cutting current effectively.

The following complications have been directly related to the sterilization. Salpingitis has been noted.[8] One patient was found to have a tubo-ovarian abscess four weeks after surgery.[14] Another patient required drainage of a pelvic abscess after therapeutic abortion and laparoscopic sterilization.[13] The serosa of the colon has been electrocoagulated on one occasion without complication.[12] Twice the small bowel has been coagulated, leading to resection in both instances.[9] Other reported complications related to the laparoscopy are perforation of the stomach[12] or the bowel,[9,20,24] postoperative pneumonia,[10] herniation of the omentum through the umbilical incision,[18] and anesthesia problems.[18] The overall percentage of significant problems, however, remains acceptably low. In the large combined experience of Palmer and Steptoe, it has been said that no significant complications have occurred.[23]

In our practice, 135 laparoscopies have been performed. Approximately 25% of these patients had previous abdominal surgery; on no occasion did this prohibit performance of the intended operation. Sixty-seven patients had laparoscopic sterilization, several of these patients requesting tubal severance at the same time as curettage for abnormal bleeding or laparoscopy for diagnosis of pelvic pain. There have been no instances of febrile morbidity, abscesses, hematomas, or pregnancy. One patient required immediate laparotomy to achieve hemostasis in the mesosalpinx. The patients generally remained in the hospital 24 hours after the procedure, and returned to full activity in two to seven days. Vaginal tubal sterilization recently has been reported to have complication rates of 9.6%[28] and 2.4%.[29] Our preliminary series would seem to compare favorably with these figures.

Summary

Improved methods of family limitation must be discovered to meet ever increasing demands by fertile couples. Male sterilization is a simple and effective procedure with low morbidity and has achieved popularity. For some couples, however, the woman must be the one to undergo a surgical procedure for termination of fertility. Laparoscopic sterilization is a rapid method associated with low morbidity and minimal hospitalization. Patients may make use of these advantages without sacrificing effectiveness.

In Memoriam

Lovely in death the beauteous ruin lay.

RALPH B. JOHNSON, M.D.

Dr. Ralph B. Johnson, Lanesboro physician, died September 4. Born in LaCrosse, Wisconsin, Dr. Johnson attended the Northwestern University Medical School.

He was a member of the Olmsted, Houston, Fillmore and Dodge County Medical Society, the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, Edna, and two children.

BURTON C. FORD, M.D.

Dr. Burton C. Ford, 80, Marshall physician died October 17. Born in Winona, Minnesota, Dr. Ford received his medical education at the University of Minnesota.

He was a member of the Lyon-Lincoln Medical Society, the Minnesota State Medical Association and the American Medical Association, and was a former member of the State Board of Nursing Examiners.

Dr. Ford is survived by his wife, Loretta, and four children.

JOSEPH C. MICHAEL, M.D.

Dr. Joseph C. Michael, 82, Minneapolis neurologist, died September 2. A native of Jordan, Dr. Michael was a graduate of the University of Minnesota Medical School and did postgraduate work in France and Austria.

He was a former clinical professor at the University of Minnesota and a former chief of staff of the neuro-psychiatric department at Hennepin County General Hospital. He was a member of the American Board of Psychiatry and Neurology, Hennepin County Medical Society and the American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association. Dr. Michael was also a former staff member of various local general and private hospitals.

Dr. Michael is survived by his wife, Blanche, and a son, Joseph, Jr.

NELS G. MORTENSEN, M.D.

Dr. Nels G. Mortensen, 87, died October 23. He had been a physician and surgeon in St. Paul for 35 years. His medical education was obtained at the University of Minnesota Medical School.

He had been president of the State Board of Health for 15 years, past Grand Chef de Gare of the Minnesota 40 & 8, a past president, 50 Club and Life member of the Minnesota State Medical Association, and a member of the American Medical Association and the Park Region Medical Society.

Dr. Mortensen is survived by his wife, Violet.

EARL J. BLACK, M.D.

Dr. Earl J. Black, 67, died February 10. Born in Bemidji, Dr. Black was a St. Paul area resident 39 years, and had been in private practice here following service with the Army in World War II.

He was a member of the American Medical Association and the Ramsey County Medical Society and an Associate Member of the Minnesota State Medical Association.

Dr. Black is survived by his wife, Ramona, a son, Anthony, and two daughters, Sara and Susan.

HELEN L. HABERER, M.D.

Dr. Helen L. Haberer, 65, head of the Department of Gynecology at the University of Minnesota Health Service, died February 1. She had been a member of the staff at the health service since 1952 and had directed the gynecology department since 1958.

She was born in Fergus Falls, Minnesota and received her medical degree from the University of Minnesota.

Dr. Haberer was a member of the American Medical Association, the Minnesota State Medical Association and the Hennepin County Medical Society.

SIMON G. SAX, M.D.

Dr. Simon G. Sax, 64, internist, died January 5. A native of Eveleth, he was a graduate of the University of Minnesota Medical School. He began his practice in Duluth in 1936 and had lived there since.

Dr. Sax was a member of the American Medical Association, Minnesota State Medical Association and the St. Louis County Medical Society. He was also a member of the Minnesota Academy of Science and the Minnesota Medical Foundation.

Dr. Sax is survived by his two brothers, Dr. Milton Sax and Jonathan G. Sax.

HARLAN A. ALEXANDER, M.D.

Dr. Harlan Alexander, 65, surgeon, died November 19. Born in Minneapolis, Dr. Alexander attended the University of Minnesota Medical School.

He was a member of the American Medical Association, Minnesota State Medical Association and the Hennepin County Medical Society.

Dr. Alexander is survived by his wife, Esther, and two sons, Doctors Harlan G. Alexander and David Alexander.

HENRY V. HANSON, M.D.

Dr. Henry V. Hanson, 82, of Green Valley, Arizona, died October 12. Born in Hutchinson, Minnesota, Dr. Hanson studied medicine at the University of Illinois, graduating in 1912. After serving in the military service, he practiced as an ENT specialist in Willmar. In 1923 he joined the staff of the Veterans' Bureau.

He was a diplomat of the American Academy of Ophthalmology and Otolaryngology, a former Assistant Clinical Professor of Otolaryngology at the University of Minnesota, a member of the American Medical Association and the Hennepin County Medical Society, and a 50 Club and Associate Member of the Minnesota State Medical Association.

Dr. Hanson is survived by his wife, Ethel, and a daughter, Evelynne.

ERNEST R. STERNER, M.D.

Dr. Ernest Sterner, 65, a surgeon practicing in St. Paul, died December 29. Born in Cambridge, Minnesota, his medical education was obtained at the University of Minnesota Medical School.

Dr. Sterner was a former Health Officer of Birchwood, former Ramsey County deputy coroner, and a member of the American Medical Association, Minnesota State Medical Association and the Ramsey County Medical Society.

He is survived by his wife, Virginia, and a daughter, Diana, two of his brothers, Dr. Donald Sterner and Dr. Otis Sterner, practice medicine in St. Paul.

DAVID J. VAIL, M.D.

Dr. David J. Vail, director of medical services for the Minnesota Department of Public Welfare for the last 11 years, died October 21. A native of Cincinnati, Ohio, Dr. Vail received his M.D. degree from Harvard University in 1948. A psychiatrist, Dr. Vail, as medical director, was in charge of the state mental health system, including 10 major institutions for the mentally ill and retarded and statewide networks of community mental health and day activity centers. One of his key accomplishments in Minnesota was initiation of an effort to remove "dehumanization" from state hospitals. He established humane practices committees at state institutions to review both major and minor complaints from patients.

Dr. Vail was a member of the American Medical Association, the Minnesota State Medical Association and the Ramsey County Medical Society.

He is survived by his wife, Joane, four sons, and three daughters.

REUBEN ERICKSON, M.D.

Dr. Reuben Erickson, 75, obstetrician and gynecologist, died December 31. Born in Scandia, Minnesota, Dr. Erickson obtained his degree from the University of Minnesota Medical School.

He was a member of the American Medical Association and the Hennepin County Medical Society and a Life Member of the Minnesota State Medical Association.

Dr. Erickson is survived by his wife, Hazel, daughter, Patricia, and son, Dr. Hartley John Erickson.

CHARLES MICHAEL JESSICO, M.D.

Dr. Charles Michael Jessico, 63, a physician specializing in neurology and psychiatry, died February 17. He had been associated with the Duluth Clinic for 26 years. His medical education was obtained at Loyola University, School of Medicine, in Chicago.

He was a member of the American Medical Association, the Minnesota State Medical Association, and the St. Louis County Medical Society.

Dr. Jessico is survived by his wife, Avanelle, and two sons, Charles and Ronald.

JOHN W. SCHUT, M.D.

Dr. John W. Schut, 51, Anoka physician and specialist in neurology, died February 17, of the disease he had spent nearly all of the latter part of his life studying. He was one of the founders of the National Ataxia Foundation, set up to combat the mysterious disease.

His medical degree was obtained from the Northwestern University Medical School, and he was a member of the American Medical Association, the East Central Medical Society, and an Associate Member of the Minnesota State Medical Association.

Dr. Schut is survived by his wife, Mary.

HENRY S. BLOCH, M.D.

Dr. Henry S. Bloch, 55, internist, died January 10. Born in Munich, Germany, Dr. Bloch's medical education, however, was obtained at the University of Minnesota Medical School.

He was a clinical instructor in the Department of Medicine, University of Minnesota and a member of the American Medical Association, Minnesota State Medical Association, and the Hennepin County Medical Society.

Dr. Bloch is survived by his wife, Maxene.

Mylanta®
24 million hours a day.

Through the day, every day,
ulcer patients take
one million doses of Mylanta
for relief of ulcer pain.

Mylanta®
LIQUID/TABLETS
aluminum and magnesium hydroxides plus simethicone

Good taste = patient acceptance
Relieves G.I. gas distress*
Non-constipating

*with the defoaming action of simethicone

a new outlook in chronic pain

of moderate to severe intensity

Though Talwin® can be compared to codeine in analgesic efficacy, it is not a narcotic. So patients receiving Talwin for prolonged periods face fewer of the consequences you've come to expect with narcotic analgesics. And that, in the long run, can mean a better outlook for your chronic-pain patient.

Talwin Tablets are:

- **Comparable to codeine in analgesic efficacy:** one 50 mg. Talwin Tablet appears equivalent in analgesic effect to 60 mg. (1 gr.) of codeine. Onset of significant analgesia usually occurs within 15 to 30 minutes. Analgesia is usually maintained for 3 hours or longer.
- **Tolerance not a problem:** tolerance to the analgesic effect of Talwin Tablets has not been reported, and no significant changes in clinical laboratory parameters attributable to the drug have been reported.
- **Dependence rarely a problem:** during three years of wide clinical use, only a few cases of dependence have been reported. In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.
- **Not subject to narcotic controls:** convenient to prescribe—day or night—even by phone.
- **Generally well tolerated by most patients:** infrequently cause decrease in blood pressure or tachycardia; rarely cause respiratory depression or urinary retention; seldom cause diarrhea or constipation. If dizziness, lightheadedness, nausea or vomiting are encountered, these effects tend to be self-limiting and to decrease after the first few doses. (See last page of this advertisement for a complete discussion of adverse reactions and a brief discussion of other Prescribing Information.)

50 mg. Tablets

Talwin®

brand of

pentazocine (as hydrochloride)

the long-range analgesic

a new outlook in chronic pain

of moderate to severe intensity

Contraindications: Talwin, brand of pentazocine (as hydrochloride), should not be administered to patients who are hypersensitive to it.

Warnings: *Head Injury and Increased Intracranial Pressure.* The respiratory depressant effects of Talwin and its potential for elevating cerebrospinal fluid pressure may be markedly exaggerated in the presence of head injury, other intracranial lesions, or a pre-existing increase in intracranial pressure. Furthermore, Talwin can produce effects which may obscure the clinical course of patients with head injuries. In such patients, Talwin must be used with extreme caution and only if its use is deemed essential.

Usage in Pregnancy. Safe use of Talwin during pregnancy (other than labor) has not been established. Animal reproduction studies have not demonstrated teratogenic or embryotoxic effects. However, Talwin should be administered to pregnant patients (other than labor) only when, in the judgment of the physician, the potential benefits outweigh the possible hazards. Patients receiving Talwin during labor have experienced no adverse effects other than those that occur with commonly used analgesics. Talwin should be used with caution in women delivering premature infants.

Drug Dependence. There have been instances of psychological and physical dependence on parenteral Talwin in patients with a history of drug abuse and, rarely, in patients without such a history. Abrupt discontinuance following the extended use of parenteral Talwin has resulted in withdrawal symptoms. There have been a few reports of dependence and of withdrawal symptoms with orally administered Talwin. Patients with a history of drug dependence should be under close supervision while receiving Talwin orally.

In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.

Acute CNS Manifestations. Patients receiving therapeutic doses of Talwin have experienced, in rare instances, hallucinations (usually visual), disorientation, and confusion which have cleared spontaneously within a period of hours. The mechanism of this reaction is not known. Such patients should be very closely observed and vital signs checked. If the drug is reinstituted it should be done with caution since the acute CNS manifestations may recur.

Usage in Children. Because clinical experience in children under 12 years of age is limited, administration of Talwin in this age group is not recommended.

Ambulatory Patients. Since sedation, dizziness, and occasional euphoria have been noted, ambulatory patients should be warned not to operate machinery, drive cars, or unnecessarily expose themselves to hazards.

Precautions: *Certain Respiratory Conditions.* Although respiratory depression has rarely been reported after oral administration of Talwin, the drug should be administered with caution to patients with respiratory depression from any cause, severe bronchial asthma and other obstructive respiratory conditions, or cyanosis.

Impaired Renal or Hepatic Function. Decreased metabolism of the drug by the liver in extensive liver disease may predispose to accentuation of side effects. Although laboratory tests have not indicated that Talwin causes or increases renal or hepatic impairment, the drug should be administered with caution to patients with such impairment.

Myocardial Infarction. As with all drugs, Talwin should be used with caution in patients with myocardial infarction who have nausea or vomiting.

Biliary Surgery. Until further experience is gained with the effects of Talwin on the sphincter of Oddi, the drug should be used with caution in patients about to undergo surgery of the biliary tract.

Patients Receiving Narcotics. Talwin is a mild narcotic antagonist. Some patients previously receiving narcotics have experienced mild withdrawal symptoms after receiving Talwin.

CNS Effect. Caution should be used when Talwin is administered to patients prone to seizures; seizures have occurred in a few such patients in association with the use of Talwin although no cause and effect relationship has been established.

Adverse Reactions: Reactions reported after oral administration of Talwin include *gastrointestinal:* nausea, vomiting; infrequently constipation; and rarely abdominal distress, anorexia, diarrhea. *CNS effects:* dizziness, lightheadedness, sedation, euphoria, headache; infrequently weakness, disturbed dreams, insomnia, syncope, visual blurring and focusing difficulty, hallucinations (see *Acute CNS Manifestations* under WARNINGS); and rarely tremor, irritability, excitement, tinnitus. *Autonomic:* sweating; infrequently flushing; and rarely chills. *Allergic:* infrequently rash; and rarely urticaria, edema of the face. *Cardiovascular:* infrequently decrease in blood pressure, tachycardia. *Other:* rarely respiratory depression, urinary retention.

Dosage and Administration: *Adults.* The usual initial adult dose is 1 tablet (50 mg.) every three or four hours. This may be increased to 2 tablets (100 mg.) when needed. Total daily dosage should not exceed 600 mg.

When antiinflammatory or antipyretic effects are desired in addition to analgesia, aspirin can be administered concomitantly with Talwin.

Children Under 12 Years of Age. Since clinical experience in children under 12 years of age is limited, administration of Talwin in this age group is not recommended.

Duration of Therapy. Patients with chronic pain who have received Talwin orally for prolonged periods have not experienced withdrawal symptoms even when administration was abruptly discontinued (see WARNINGS). No tolerance to the analgesic effect has been observed. Laboratory tests of blood and urine and of liver and kidney function have revealed no significant abnormalities after prolonged administration of Talwin.

Overdosage: *Manifestations.* Clinical experience with Talwin overdosage has been insufficient to define the signs of this condition.

Treatment. Oxygen, intravenous fluids, vasopressors, and other supportive measures should be employed as indicated. Assisted or controlled ventilation should also be considered. Although nalorphine and levallorphan are *not* effective antidotes for respiratory depression due to overdosage or unusual sensitivity to Talwin, parenteral naloxone (Narcan®, available through Endo Laboratories) is a specific and effective antagonist. If naloxone is not available, parenteral administration of the analeptic, methylphenidate (Ritalin®) may be of value if respiratory depression occurs.

Talwin is not subject to narcotic controls.

How Supplied: Tablets, peach color, scored. Each tablet contains Talwin (brand of pentazocine) as hydrochloride equivalent to 50 mg. base. Bottles of 100.

Winthrop Winthrop Laboratories, New York, N. Y. 10016 (1583

Minnesota State Medical Association

It's All Set for You in '72

119th Annual Meeting

ROCHESTER WILL be the host city for the 119th Annual Meeting of the Minnesota State Medical Association May 18, 19 and 20. Members of the Zumbro Valley Medical Society will be the hosts for the 1972 Upper Midwest's Great Medical Meeting.

In its continued effort to introduce innovations for the meeting, the Committee on Scientific Assembly has approved a program format which will include three concurrent morning sessions for Thursday and Friday. Each session will feature eight mini-sessions 10, 15 or 20 minutes in length.

Afternoon sessions for both days will each feature a series of five "in depth" concurrent panels and roundtables.

Morning sessions will begin at 9:00 A.M. in North Hall, South Hall and the Theater Section of Mayo Civic Auditorium.

The afternoon panels will begin at 2:00 P.M. and will also be held in the Mayo Civic Auditorium locations.

The meeting will feature outstanding scientific and technical exhibits. Recess breaks between sessions have been scheduled at 10:15 A.M. and 3:00 P.M. to give physicians the opportunity to view the exhibits.

Specialty Societies Participate

A number of specialty societies have scheduled annual meetings in conjunction with the 119th Annual Meeting, including the following: Minnesota Society of Clinical Pathologists—May 20; Minnesota Academy of Ophthalmology & Otolaryngology—May 19; Minnesota Chapter of American Academy of Pediatrics—May 19; Minnesota Physiatric Society—May 19; Minnesota Chapter of the American College of Surgeons—May 19 and the Minnesota Chapter of the Flying Physicians Association—May 20.

The Minnesota Chapter of the American College of Surgeons will again sponsor the Friday (May 19) morning program. The Committee on Alcoholism and Drug Abuse will sponsor a presentation titled "The Recognition and Management of the Dependent Person" May 18. The Committee on Environmental Health will sponsor a panel Friday, May 19.

"Something for Everyone"

There will be nearly 100 participants in the 48 mini-sessions, 16 panels and luncheons of the Scientific Program. The Committee on Scientific Assembly is pleased to announce a program which will include a wide range of pertinent and stimulating subjects. Included in the Thursday afternoon panels will be one titled "Meet the Medical School Deans." With the expansion of medical school facilities in Minnesota, this occasion will provide physicians the opportunity to learn more about what's in store for Minnesota. Participants include: H. Drew Miller, M.D., Chairman; Panel Members: Robert E. Carter, M.D., Ward S. Fowler, M.D., and Mead Cavert, M.D. Synopsis of some of the papers scheduled for presentation are listed at the end of this article.

Luncheon Speakers Named

Doctor Charles Edwards, Commissioner of Food and Drugs, Department of HEW, and Doctor Malcolm Moos, President of the University of Minnesota, will be guest luncheon speakers at this year's meeting. The annual banquet has been scheduled for Thursday, May 18, at the Kahler Hotel. Members who have completed fifty years in the practice of medicine in the State of Minnesota will be accepted into the membership of the Fifty Club of the Minnesota State Medical Association. Many of the more than fifty scientific and non-scientific committees of the Association have scheduled breakfast meetings in conjunction with the Anuual Meeting, and physicians are urged to attend and take an active role in the affairs of their respective committees.

Business Sessions Set

The Thursday-Friday scientific program marks a departure from the traditional beginning of the week dates in previous years. Prior to this beginning of the scientific program, the House of Delegates will convene for its opening session Wednesday, May 17, at 1:00 P.M. in the Kahler Hotel. Reference Committees will meet following the opening session of the House to consider resolutions, officers and councilors reports, reports of committee chairmen, etc. The second session of the House will convene Friday, May 19 at 2:00 P.M.

Minnesota Chapter of the Flying Physicians Association

Luncheon Meeting—Saturday, May 20, 12:00 Noon, Gold Room of the Holiday Inn Downtown, Tickets: $4.25. All physicians interested in flying are inivited to attend. Advance reservations requested. Contact: Alex Webb, Jr., M.D., 311 Terminal Building, Mpls.-St. Paul International Airport, or Frank J. Bonello, M.D., 1074 So. Robert Street, W. St. Paul.

Woman's Auxiliary

The Woman's Auxiliary will observe its 50th anniversary at its annual meeting held in conjunction with the annual meeting of the Association in Rochester. The tentative program is as follows: Thursday, May 18—Executive Board Meeting and Luncheon, Kahler Hotel. Afternoon Tea—Mayo Foundation House. Friday, May 19—Annual Meeting, Kahler Hotel—Luncheon, Rochester Golf Country Club. General arrangements are being made by Mrs. Philip E. Bernatz and Mrs. James A. Bastron, Rochester.

1972 Tentative Program Timetable

Wednesday, May 17

1:00 P.M.	House of Delegates First Session—Kahler Hotel
4:30 P.M.	Reference Committees—Kahler Hotel
6:00 P.M.	Delegates and Councilors Dinner—Kahler Hotel
8:00 P.M.	Reference Committees Reconvene—Kahler Hotel

Thursday, May 18

7:30 A.M.	Committee Breakfasts—Kahler Hotel
8:00 A.M.	Registration—Mayo Civic Auditorium
9:00 A.M.	Scientific Session Begins—Mayo Civic Auditorium
12:15 P.M.	Luncheon—Kahler Hotel
2:00 P.M.	Scientific Sessions Continue-Afternoon Panels—Mayo Civic Auditorium and Art Center
6:00 P.M.	President's Reception—Kahler Hotel
7:00 P.M.	Annual Banquet—Kahler Hotel

Friday, May 19

7:30 A.M.	Committee Breakfasts—Kahler Hotel
8:00 A.M.	Registration—Mayo Civic Auditorium
9:00 A.M.	Scientific Session—Mayo Civic Auditorium
12:15 P.M.	Luncheon—Kahler Hotel
2:00 P.M.	Scientific Sessions Continue-Afternoon Panels—Mayo Civic Auditorium and Art Center
2:00 P.M.	House of Delegates Second Session—Kahler Hotel

Saturday, May 20

Specialty Group Meetings—
Specialty groups will be holding their annual meetings in conjunction with the Association Annual Meeting, Friday and Saturday.

Scientific Program

1972 Annual Meeting Minnesota State Medical Association

Thursday

9:00- 9:15 A.M. Laparoscopy—Jack E. Wall, M.D.

9:00- 9:15 Vesicoureteral Reflux—Panayotis P. Kelalis, M.D.

Retrograde flow of urine to the kidneys is closely linked to urinary infection. The incidence of vesicoureteral reflux is high in the first five years of life and then decreases sharply. Therefore, reflux is not a permanent phenomenon in all instances, and in many cases it may simply represent delayed maturation of the ureterovesical angle.

9:00- 9:15 Exercise as Treatment in Coronary Heart Disease—James I. Thompson, M.D.

Exercise may result in a beneficial effect on the natural history of ischemic heart disease. The incidence of myocardial infarction recurrence and death, appears to be reduced. An exercise program is also helpful in improving exercise tolerance, and may be of psychological benefit. One-third of the patients are capable of training at exercise levels greater than walking and self care. An individual program can be prescribed to limit the level of exertion, below that used for exercise testing. Steady state exercises as walking or bicycling are best. The prescribed exercise is carried out for thirty minutes, at least three times a week. Progression of exercise level may be possible, after a stress test re-evaluation.

9:20- 9:35 Surgical Emergencies in the Newborn—Bernard J. Spencer, M.D.

9:20- 9:35 Emergency Medical Care From Accident Site to Hospital—Claude R. Hitchcock, M.D.

9:20- 9:35 Polychemotherapy of Lymphoma—Irving J. Lerner, M.D.

Current multidrug therapy differs from the previous approach in two major ways: (1) an effort is made to select drugs which have in common known antitumor effect against the malignancy to be treated, but differ in the forms of their toxicity, and (2) the drugs are administered in an intermittent or "pulsating" rather than continuous fashion.

9:40- 9:55 Fetal Monitoring—David L. Hill, M.D.

9:40- 9:55 Coronary Artery Surgery—Demetre M. Nicoloff, M.D.

Myocardial infarction with its immediate mortality and subsequent morbidity constitute a major medical problem for the young and middle-aged male in the United States. Prodromal symptoms that often precede infarction are angina of recent onset or an increase in the severity and frequency of occurrence of angina. With the coronary arteriography and aortocoronary saphenous vein bypass, a new approach has been made available to treat preinfarction angina or angina unresponsive to medical therapy. The procedure offers an immediate and possibly, a lasting, increase in myocardial blood flow.

9:40- 9:55 Use of L-Dopa in Parkinson's Disease—Lawrence A. Farber, M.D.

10:00-10:10 Hyperbilirubinemia of the Newborn—Charles W. Jarvis, M.D.

10:00-10:10 Hemorrhoids: Surgery vs No Surgery—William T. Smith, M.D.

These past twenty-five years the most recommended treatment for hemorrhoids is surgery. This involves a hemorrhoidectomy that removes all varicosities, both internal and external, down to the sphincter mechanism and the circular muscle of the rectum. If residual hemorrhoids remains, ordinarily they will hypertrophy and become symptomatic. If hemorrhoids are properly removed, recurrence is minimal. Whenever injection treatment or ligation is used, the external hemorrhoids still have to be dealt with. These may be excised one at a time in the office using a local anesthetic and may require several patient visits. The best treatment offered to the low risk surgical patient is a one stage surgical excision of all the internal and external hemorrhoids using one of several standard techniques which destroys all anal-dermal and submucosal varicosities. One suggestion that has been made is that perhaps the entire problem of hemorrhoids could be resolved if man returned to quadrupedism.

Thursday (continued)

10:00-10:10 *Can Gallstones be Dissolved Medically?—Johnson L. Thistle, M.D.*

Most gallstones are composed predominantly of cholesterol. This lipid is normally excreted in bile, an aqueous solution, and is solubilized by incorporation into aggregates of bile acid molecules called "micelles." The capacity of these micelles to dissolve cholesterol is limited but is greatly increased by inclusion of the phospholipid, lecithin. Preliminary obervations have demonstrated disappearance of gallstones in one patient and marked decrease in stone size in three others after 6 to 22 months of treatment.

10:45-11:00 *Occular Complications of Commonly Used Topical and Systemic Medications—Dennis M. Robertson, M.D.*

Physicians must be alert to possible complication of commonly used medications.

10:45-11:00 *Surgical Treatment of Thyroid Nodules—Oliver H. Beahrs, M.D.*

A thyroid gland, diffusely firm and nodular, suspected of being Hashimoto's Thyroiditis, may be biopsied by a Silverman needle. If the diagnosis is correct, treatment is thyroid replacement therapy. Fibrous (Riedel's) thyroiditis may be indistinguishable from cancer and must be explored. The incidence of cancer in nodular goiters surgically removed is about 12-15%.

10:45-11:00 *Ambulatory Emphysema—Frank M. MacDonald, M.D.*

11:05-11:20 *Management of Malignant Melanoma—John C. Ivins, M.D.*

Cutaneous melanoma is a major malignancy for which there is no satisfactory therapy. It has a deserved reputation for being the most biologically erratic cancer with which we have to contend. For this reason, retrospective studies reporting three, five, and even ten year "cures" do not mean much in terms of deciding what constitutes adequate treatment. There are many reported instances of spontaneous regression of proven melanoma. There are even more instances of widespread metastases involvement without a known primary source, and many records relate the first appearance of metastases fifteen or more years after excision of the primary lesion. One of the urgent problems to be solved is the relationship of the regional lymph nodes to the course of the disease. The value of lymphadenectomy can probably be resolved only by prospective study, subjecting comparable patients to different treatment programs.

11:05-11:20 *Diagnosis of Diffuse Pulmonary Disease with Emphasis on Transbronchial Lung Biopsy—Howard A. Andersen, M.D.*

11:05-11:20 *The Current Treatment of Gout—Roger S. Colton, M.D.*

Effective agents for pain relief and reduction of inflammatory response includes Colchicine, Butazolidin, and Indocin. These drugs may be used as well in an attempt to prevent recurrent acute attacks. Equally as important is immobilization and complete rest of the joint or joints involved. Hot and/or cold packs, whichever gives symptomatic relief, and narcotics as needed initially are helpful adjuncts. Reduction of total body urate is done by uricosuric agents such as Probenecid (Benemid), Sulfinpyrazone (Anturane), or high doses of salicylates; Xanthine oxidase inhibitors (Zyloprin) also lower serum uric acid by inhibiting the metabolic formation of uric acid.

11:25-11:40 *Management of Asthma—James P. Lillehei, M.D.*

11:25-11:40 *Surgical Treatment of Early Lung Cancer—Josiah Fuller, M.D.*

"Early Lung Cancer" does not describe a time period but refers to the stage of the disease and is an important factor in determining the extent of surgical therapy. The more differentiated squamous and adenocarcinomas respond better to surgical therapy than the undifferentiated bronchogenic carcinomas. Small cell bronchogenic carcinoma is rarely resectable. Surgical treatment should be the minimal resection commensurate with complete removal of all cancer. When the circumstances indicate, aggressive surgical therapy including mediastinal lymph node dissection and chest wall resection should be carried out. The five year survival rate for surgically resected bronchogenic carcinomas compares favorably with that of many other internal cancers. The number of major thoracotomies for inoperable bronchogenic carcinomas should be kept to a minimum. Anterior mediastinotomy is a simple and useful procedure for determining operability of lung cancer.

Thursday (continued)

11:25-11:40 *Recurring Urinary Tract Infection in Women—Lynwood H. Smith, Jr., M.D.*

11:45-11:55 *Upper Airway Problems in Anesthesia—Joseph J. Buckley, M.D.*

11:45-11:55 *The Aggressive Approach to Asymptomatic Cholelithiasis—Edward S. Judd, M.D.*

The extreme medical view holds that surgery for "silent" gallstones cannot be defended. The extreme surgical view urges cholecystectomy for every case of gallstones. We advise careful consideration of the operative risk of early elective surgery, versus the risk of later elective surgery and even emergency surgery for increasing symptoms. Autopsy studies reveal that 23 percent of males and 46 percent of females between the ages of 70 and 79 years have gallstones. Retrospective survey proves symptoms existed in 40 percent of the patients. A study here concerning 112 patients who were found to have incidental gallstones, reveals 25 percent developed dyspepsia and 20 percent developed colic. Forty-five percent developed significant symptoms of some kind. In another study of 34 "silent gallstone" cases, one out of five developed serious complications later. For younger patients we advocate prophylactic cholecystectomy. For the aged patient, we must individualize considering the life expectancy, the greater operative risk, and the competing risks.

11:45-11:55 *The Irritable Colon Syndrome—William D. Blackwood, M.D.*

The vulnerability of the gastrointestinal tract to adverse life situations is reflected in the frequency with which the irritable colon syndrome is seen. The common symptoms of bloating, pressure, pain, flatulence and alternating diarrhea and constipation with relief by emptying the colon appear to be related to abnormal motility and exaggerated normal physiologic activity. Motility studies have clarified some of the mechanisms of symptom production.

Friday

9:00- 9:15 A.M. *New Antibiotics—Robert P. Gruninger, M.D.*

9:00- 9:15 *Current Treatment of Gonorrhea—Arnold L. Schroeter, M.D.*

Controlling the gonorrhea epidemic in the United States will depend on adequate antibiotic treatment of the infected patient. Despite partial antibiotic gonococcal resistance, procaine penicillin G is still the treatment of choice. Although many partially antibiotic-resistant gonococcal strains have been imported from the Orient, most of our resistant strains have been developed in the United States by inadequate treatment schedules.

9:00- 9:15 *Neurosurgery: New Methods for Pain Control—Donlin M. Long, M.D.*

9:20- 9:35 *Chemotherapy of TB—David T. Carr, M.D.*

The chemotherapy of tuberculosis is truly one of the miracles of modern medicine. Presently available drugs are so effective that cure of the disease is not only to be expected but should be demanded. The death rate attributed to this disease should fall to zero if every case were diagnosed before the patient was moribund, the proper regimens of drug prescribed, and the drugs taken faithfully by the patient.

9:20- 9:35 *Evaluation of Borderline Hypo- and Hyperthyroidism—Alvin L. Schultz, M.D.*

I^{131} uptake has been suppressed by the addition of iodide to commercial breads. The mean value at 24 hours in euthyroid persons has been reduced to 13 to 15% and the upper limit of normal is probably no more than 30%. Values above 25% should be considered suspicious of hyperthyroidism. Thyroid I^{131} uptake has become of little value in the diagnosis of hypothyroidism because of the lowered normal values. Serum protein-bound iodine is being replaced by the measurement of serum thyroxine by saturation analysis (Murphy-Pattee), a much more sensitive and reliable method for the diagnosis of both mild hypo- and hyperthyroidism. Measurement of serum free thyroxine and free triiodothyronine are now possible and may be the most sensitive means for the diagnosis of mild hyperthyroidism. Mild hypothyroidism has always been difficult to diagnose on clinical or laboratory grounds. The

Friday (continued)

availability of a reliable measurement of serum thyrotropin (TSH) by radioimmunoassay is proving to be the most sensitive and effective way to diagnose early and mild primary hypothyroidism. TSH levels become elevated very early in the course of primary hypothyroidism usually before clear-cut clinical signs are apparent. The recognition that hyperthyroidism can be produced by elevation of triiodothyronine without an associated increase in serum thyroxine explains some of the cases which in the past have been confusing to the clinician.

9:20- 9:35 *Plastic Surgery: Snowmobile Injuries—Conrad I. Karleen, M.D.*

9:40- 9:55 *Urinary Tract Infection in Children—Warren J. Brooker, M.D.*

Urinary tract infection frequently causes childhood illness. It is among the most common sources of fever in children. Complete urologic evaluation including cystogram, IVP, and endoscopy is indicated in all boys with infection. Girls with repeated or persistent pyuria, all cases in which the cultured organism—proteus or pseudomonas—suggests chronicity, and all children with hematuria or "sterile" pyuria also require investigation. *Relative* indications are "failure to thrive", anema, azotemia, hypertension, auricular, or genital anomalies, and suggestive family history. Pyelonephritis is an incomplete diagnosis inasmuch as there is "always" an associated anatomic or physiologic defect which must be corrected to effect a cure. Treatment must include a systemically effective drug during the septic state, surgical correction of anatomic defects and suppressive drug therapy for a prolonged period during recovery.

9:40- 9:55 *Ear, Nose, Throat: Trauma to the Larynx—Jerome A. Hilger, M.D.*

9:40- 9:55 *Recent Advances in Cancer Treatment—Radiation Therapy—Seymour H. Levitt, M.D.*

10:00-10:10 *Alternate Day Corticosteroid Treatment—Richard G. VanDellen, M.D.*

Despite complications of steroid drugs, they remain effective and necessary therapy for some patients with asthma, pemphigus, nephritis, rheumatoid arthritis, and other diseases. Prednisone administered by a single morning dose on alternate days does not suppress the adrenal-pituitary axis. A single dose of steroids given on alternate days causes fewer side-effects than comparable doses given daily. Prednisone, prednisolone, or methylprednisolone should be used on alternate days but not triamcinoline or dexamethasone, both of which have a longer suppressive effect on the pituitary-adrenal axis. Hydrocortisone and cortisone have not been used because of sodium retention. Alternate-day steroid therapy is effective in patients with asthma. After first controlling the asthma with daily doses of steroids, alternate-day therapy is instituted. Forty mg of Prednisone by mouth in one dose to be taken in the morning every other day. Decreased 5 to 10 mg every fourth to sixth dose is typical although 80 to 120 mg every other day have been used with minimal side effects. Preliminary evidence suggests that diseases such as lupus erythematosus, nephritis, and pemphigus also may be controlled by steroids taken every other day.

10:00-10:10 *Urographic Techniques in the Diagnosis of Renal Masses—Elwin E. Fraley, M.D.*

10:00-10:10 *General Surgery: Hyperalimentation, Intravenous—Robert L. Telander, M.D.*

10:45-11:00 *The Diagnosis and Treatment of Nocturnal Enuresis—Daniel C. Merrill, M.D.*

The bladder function of 39 enuretic children was evaluated with air cystometry. Approximately 50 percent of these children had normal bladder function for age. The remaining had reduced bladder capacities. Bedwetters with normal bladder function usually were deep sleepers while enuretics with small bladder capacities had normal sleep patterns. Deep sleepers with normal bladder function were treated with conditioned response therapy. Children with small bladder capacities were treated with holding exercises and Tincture of Belladonna. Eighty percent of the entire group were cured (21 consecutive dry nights). Twenty percent relapsed, this group usually responded to a second short period of conditioned response therapy.

Friday (continued)

10:45-11:00 *Serum Multiple Analysis Patterns in Diagnosis of Disease—Richard L. Reece, M.D.*

New technology, (multichannel chemical analyzers, multitest hematology instruments, and computers) makes pattern recognition of disease inevitable. You can now do many tests inexpensively, rapidly, and accurately on one sample. Given many results together, you begin to perceive patterns: clusters of abnormals that occur in disease states, in non-fasting specimens, or after certain drugs. You see results in perspective rather than in isolation. You see patterns.

10:45-11:00 *Gynecology: Vaginal Hysterectomy in Younger Women for Sterilization—Tiffany J. Williams, M.D.*

11:05-11:20 *"Brittle" Juvenile Diabetics Often Are Victims of Unrecognized Compensatory Hyperglycemia—the Somogyi Effect—Henry S. Sauls, M.D.*

About 3% of insulin dependent diabetics are difficult to regulate. Management problems have been induced by over-treatment with insulin in about 15% of juvenile diabetics attending classes at the Diabetes Education Center.

11:05-11:20 *Treatment of Hyperlipidemia—John L. Jnergens, M.D.*

11:05-11:20 *General Surgery: Bile Acid Metabolism: Surgical Significance—Alan F. Hofmann, M.D.*

The surgical significance of bile acids is as follows: (1) virtually all patients with resection or bypass of the terminal ileum have bile acid malabsorption and a compensatory increase in synthesis; the increased passage of bile acids into the colon causes a watery diarrhea which responds to cholestyramine. (2) In patients with large resections of the ileum, interruption of the enterohepatic secretion of bile acids causes fat maldigestion and fat malabsorption. Removal of fat from the diet (made possible by equicaloric replacement with medium chain triglyceride) may improve diarrhea. (3) A new syndrome of hyperoxaluria associated with nephrolithiasis has been noted in patients with ileal resection. This appears to be related to increased conjugation of bile acids with glycine and may respond to oral taurine therapy. (4) Cholesterol cholelithiasis is associated with a diminished bile acid pool. (5) In patients with stagnant intestinal loops, bacterial overgrowth causes increased bile acid deconjugation leading to decreased concentration of conjugated bile acids.

11:25-11:40 *Current Concepts in the Treatment of Osteoporosis—David L. Hoffman, M.D.*

Involutional (postmenopausal or senile) osteoporosis is still of unknown cause, although it appears that age, sex, race, calcium intake and absorption, gonadal function, and skeletal stress all play a role in its development. Treatment has been largely empirical with a strong placebo effect suspected with almost all modes of therapy.

11:25-11:40 *Choice of Treatment in Patients with Hypertension—Louis A. Tobian, M.D.*

11:25-11:55 *Orthopedics: Total Hip and Other Joint Replacement—Mark B. Coventry, M.D.*

11:45-11:55 *Cutaneous Clues to Systemic Malignancy—Harold O. Perry, M.D.*

One must identify the skin reaction as specifically as possible. This might require the use of skin biopsy or immunofluorescent techniques. Some patients with cutaneous alterations based on hereditary patterns who have developed malignant disease have altered immunologic competence on appropriate laboratory testing. Cases illustrating cutaneous lesions indicative of systemic malignant disease wll be presented.

11:45-11:55 *Clinical Assessment of "Bleeders"—William R. Swaim, M.D.*

Bleeding is due to defects in blood vessels, platelets or plasma coagulation. The nature of the bleeding is helpful in diagnosis. Platelet and/or vascular abnormalities are associated with superficial bleeding such as petechiae, epistaxis, menorrhagia, and gingival bleeding. Patients with plasma coagulation abnormalites more commonly have deep bleeding such as hemarthroses and muscle hematomas. If disseminated intravascular coagulation is considered then additional tests that may be helpful include a thrombin time, fibrinogen and fibrin split product assessment, detection of fibrinonomer by the serially diluted protamine sulfate test, fibrinogen quantitation and if available a factor V assay.

Thursday Afternoon — Panels

2:00- 5:00 P.M. *The Recognition and Management of the Dependent Person—Subcommittee on Alcoholism and Drug Abuse of the Committee on Mental Health, Minnesota State Medical Association—Myron R. Wilson, Jr., M.D. Program Chairman*

The Subcommittee of Drug Abuse and Alcoholism will focus on the person, not the problem, in the scientific presentation at the Annual Meeing this May. The forum will include a general discussion of dependency in persons, and specific clinical situations will describe the means by which physicians can detect manifestations, recognize symptoms, and treat the person, who is suffering from dependent related problems.

2:00- 3:00 *Surgical Treatment of Dumping Syndrome—Martin A. Adson, M.D., Chairman; Panel Members—Henry Sosin, M.D., Michael M. Eisenberg, M.D., William D. Blackwood, M.D.*

2:00- 3:00 *Arrhythmias, Blocks, Pacemakers—Yang Wang, M.D., Chairman; Panel Members—Edward A. Ryan, M.D., A. McDonnell Richards, M.D., John P. Stokes, M.D.*

A brief ten-minute talk by each of the panel members as planned and then a panel discussion during which questions will be welcomed from the audience will be held.

2:00- 3:00 *Meet the Medical School Deans—H. Drew Miller, M.D., Chairman; Panel Members—Robert E. Carter, M.D., Ward S. Fowler, M.D., Mead Cavert, M.D.*

2:00- 3:00 *Transient Cerebro-Ischemic Attacks—Clark H. Millikan, M.D., Chairman; Panel Members—Arthur C. Klassen, M.D., Robert G. Siekert, M.D., Thoralf M. Sundt, Jr., M.D., Jack P. Whisnant, M.D.*

Transient cerebral-ischemic attacks are the most significant events warning that a stroke can happen. This panel will describe the importance of the attacks and how the diagnosis is established.

3:45- 5:00 *Surgical Management of Biliary Tract Problems—Donald C. McIlrath, M.D., Chairman; Panel Members—John P. Delaney, M.D., James J. Monge, M.D., Frederick M. Owens, Jr., M.D.*

Common problems encountered in surgery of the biliary tract will be considered with particular emphasis on the practical aspects of evaluation and treatment. Case histories illustrating the preoperative and operative problems will form the basis for discussion.

3:45- 5:00 *Hepatitis Associated (Australia) Antigen—Jeffrey McCullough, M.D., Chairman; Panel Members—John M. Matsen, M.D., Herbert F. Polesky, M.D., Howard F. Taswell, M.D., Johnson L. Thistle, M.D.*

3:45- 5:00 *Psychiatric Aspects of Pain—Maurice J. Martin, M.D., Chairman; Panel Members—Loran F. Pilling, M.D., Neil Yorkston, M.D., Lawrence R. Gowan, Jr., M.D.*

The problem of pain will be discussed by a panel of psychiatrists from various portions of Minnesota who are exposed to various types of practice. Various aspects of the problem including evaluation, diagnosis and therapy will be discussed. It will be emphasized that emotional aspects of pain contribute signifcantly to the perception of pain and consequently to its appropriate management. If the physician understands the emotional components and the meaning of pain to the patient, he will be in a better position to treat the patient and his symptom.

3:45- 5:00 *Mesenteric Vascular Disease—Mesenteric Arteriography—Owings W. Kincaid, M.D., Chairman; Panel Members—Kurt Amplatz, M.D., Thomas E. Johnson, M.D., Douglas B. McGill, M.D., Philip E. Bernatz, M.D.*

Vascular lesions of the mesenteric vessels, some of which may result in bowel ischemia or infarction, will be considered from the standpoint of symptomatology, radiographic and arteriographic diagnosis, and surgical treatment.

Friday Afternoon—Panels

2:00 -5:00 *Environmental Health—MSMA Committee on Environmental Health. Guest Speakers—Robert D. Moseley, Jr., M.D., William R. Fifer, M.D., Hymie Gordon, M.D., Mr. George S. Michaelson.*

The Committee on Environmental Health will focus its discussion on five environmental health topics: With its guest speakers, they will cover: (1) environmental health problems in medical practice and the hospital, (2) solid wastes and disposal, (3) radioactive sources, (4) contamination and infection and (5) the physician and population control.

2:00- 3:00 *Oral Hypoglycemic Agents—Frederick C. Goetz, M.D., Chairman: Panel Members, E. B. Cohen, M.D., Clifford Gastineau, M.D.*

The panelists will present an outline of their current practice in the use of oral hypoglycemic agents in the adult type of diabetes.

2:00- 3:00 *Massively Injured Patient—John F. Perry, Jr., M.D., Chairman; Panel Members—James H. House, M.D., Donald L. Erickson, M.D., Claude R. Hitchcock, M.D., Alexander S. Cass, M.D.*

The format of the panel discussion will be to present case histories and x-rays of patients with massive injuries. These will be chosen to illustrate surgical, orthopedic, neurosurgical and urological problems encountered in this situation. Emphasis will be primarily upon diagnostic procedures and initial treatment to be employed in the massively injured patient. Priorities for treatment of individual injuries in the multiple injury situation will be discussed also.

2:00- 3:00 *Epilepsy in Children—Robert V. Groover, M.D., Chairman; Panel Members—Kenneth F. Swaiman, M.D., Jerrold Milstein, M.D.*

This hour will be devoted to a discussion of the clinical classification, differentiation, and management of seizures in infants and children by the panel members. Particular emphasis will be placed upon neonatal seizures, "febrile seizures", clinical features of various seizure types, and the differential points between generalized and focal seizures.

2:00- 3:00 *Carcinoma of the Ovary—Konald A. Prem, M.D., Chairman; Panel Members—Leon L. Adcock, M.D., George Malkasian, Jr., M.D., Thomas K. Jones, M.D.*

Dr. Adcock will speak on Surgical Management, Dr. Malkasian on Chemotherapy and Dr. Jones on Radiotherapy of Carcinoma of the Ovary. Each presentation will be approximately 10-15 minutes. A few minutes at the end will be devoted to questions from the audience.

3:45- 5:00 *Diagnosis and Management of the Patient with an Ischemic Extremity—James R. Pluth, M.D., Chairman; Panel Members—Edward A. Ryan, M.D., Joseph C. Kiser, M.D., Jui-Sung Hung, M.D.*

Surgical aspects of acute arterial injury and thrombosis will be presented in addition to the choice of procedures for providing revascularization of the chronic ischemic limb.

3:45- 5:00 *The Family Physician—Our Most Important Link in Early Identification of Vision and Hearing Problems—Panel Members—Robert J. Fink, M.D., James B. McBean, M.D., Robert T. Kelly, M.D., Mr. Allan Tingley, Mrs. J. E. Anderson.*

The importance of early detection of vision and hearing handicaps will be discussed, including the necessity of thorough examination by the family physician of patients to uncover such deficiencies.

Friday Afternoon—Panels (continued)

3:45- 5:00 *New Concept in the Care and Management of the Cerebral Palsied—Sponsored by United Cerebral Palsy of Minnesota—Speakers—Leon Sternfield, M.D., V. Richard Zarling, M.D.*

The research and training aspects of the Foundation with particular reference to how these might apply in Minnesota. The developments that are occurring, mobilizing the most severely and multiply handicapped in some of our institutions with particular reference to the work at Faribault State School in Minnesota. The presentations would be conducted on an "interview" type basis. This would involve essentially, three or four persons to be interviewed.

3:45- 5:00 *Medical Audit—James M. Schless, M.D., Chairman; Panel Members—William R. Fifer, M.D., Robert E. Hansen, M.D., Lorenzo D. Trajano, M.D., Laurence A. Savett, M.D., Richard E. YaDeau, M.D.*

The delivery of good medical care is a goal of all physicians. Maintaining quality in the face of rapid changes in biomedical knowledge and changing patterns and expectations of health care delivery must concern all practicing physicians. Objective methods of determining quality of care actually being delivered at the local level (hospital or office) are available to physicians through the educational audit and are greatly enhanced through use of the problem-oriented record. Objective evaluation in terms of changed patterns of patient care can be obtained by periodic recheck. A pilot program has been conducted in Minnesota in five community hospitals during the past year.

Gowers' Syndrome

This syndrome consists mainly of sensory and subjective attacks to which Gowers unfortunately and erroneously applied the adjective "vagal." The attacks occurred primarily in women, whose family history was tinged with migraine, epilepsy, or insanity.

Attacks were characterized by paresthesias, dyspnea, sometimes intense, precordial discomfort in the form of pain or palpitation, and a feeling of apprehension and dread. At times the pulse was small and almost imperceptible. Facial pallor, cramplike spasm, and even rigors were present. Gowers considered the etiology to be "a disturbance of the vasomotor center." The only significance of this syndrome is that it contributed to the differentiation and clarification of the clinical concept of the vasovagal syndrome. Gowers' syndrome has no counterpart in today's diagnostic terminology.

Durham, Robert H.—Encyclopedia of Medical Syndrome
Hoeber Medical Division, Harper and Row, New York

Book Reviews

ORGANIZATION AND ADMINISTRATION OF HEALTH CARE. Richard L. Durbin and W. Herbert Springall. The C. V. Mosby Company, St. Louis, 1969, 248 pages.

This book presents a comprehensive overview of all facets of hospital organization, management and administration. Part I develops the theoretical foundations of administrative science, including among others a discussion of the Hawthorne experiments. Part II deals with both the optimal organizational scheme of a hospital and the practical problems of reorganization. In Part III economic problems of resource allocation are analyzed. Part IV deals with various questions of implementation. Of special interest are the industrial engineering techniques discussed briefly such as workload and work flow studies, and a proposed classification system. Even the subtle subject of quality control is presented in a very readable way. Part V finally develops ideas for organizational development beyond traditional ways that merit close attention.

The exposition is lucid and stimulating throughout. Diagrams and examples and case material are used felicitously. The section on business and finance contains detailed illustrative worksheets and budgets. This book should prove a valuable aid to hospital administrators. But it can be recommended also to doctors as a fascinating and reliable guide to improved understanding of the complexities that beset modern hospital management. However, no panacea for solving the perennial problem of rising costs should be expected.

Martin Beckmann, Ph.D.
Brown University

ARTHRITIS AND PHYSICAL MEDICINE. Author: Sydney Licht, M.D. Publisher: Elizabeth Licht, East New Haven, Connecticut.

This monograph encompasses manuscripts by 21 authors, all of whom have the problems of arthritis. It is reasonably comprehensive for a disease in which the etiology and specific treatment continue to remain somewhat of a mystery.

It should serve as a good source of reference for its contents and in its bibliography. I find it well illustrated with suitable line drawings, photographs and X-rays.

Carl O. Rice, M.D.
Minneapolis, Minnesota

ADVANCED GASTROINTESTINAL CANCER—CLINICAL MANAGEMENT AND CHEMOTHERAPY. By Charles G. Moertel and Richard J. Reitemeier. Harper & Row, New York.

This book is divided into two parts with 208 pages of text and 8 pages of a useful and functional index.

The first section is devoted to Clinical Management of Advanced Gastrointestinal Cancer and presents a review of various symptoms produced by the disease; problems of edema and ascites, nausea and vomiting, and the relief of pain are covered by the primary authors. Additional sections are contributed by Dr. Martin A. Adson, who reviews the role of the surgeon in palliative management, and by Donald S. Childs, Jr., on the radiation therapist and his role in palliative management. Dr. Uihlein writes on the function of the neurosurgeon, and Dr. Allen B. Gould on the role of the anesthesiologist. The philosophy of terminal care, the symptomatic relief of the numerous problems such as anemia, biliary obstruction, partial bowel obstruction, nutritional deprivation are included and some useful suggestions made. Finally, surgical and other palliative therapy is evaluated on the basis of changes or improvements in the natural history of the disease itself.

The second part of the text is devoted to Chemo-Therapy of Advanced Gastrointestinal Cancer and it begins with an evaluation of the greatest problem to the practicing physician, namely, the selection of patients for chemotherapy. The criteria for evaluation of results are presented in a forthright, scientific manner, followed by the specifics directed at each of the various types of drugs in current use. It is noteworthy that 45 pages are devoted to five fecal urobilinogen and 50 pages to all the other chemical substances combined. One helpful section reviews regional perfusion and another, chemotherapy combined with x-ray.

This volume makes a very worthwhile text for treatment and decision regarding referral of patients with advanced gastrointestinal cancer.

J. H. Strickler, M.D.
Minneapolis, Minnesota

ESSENTIALS OF CLINICAL ENDOCRINOLOGY by Norman G. Schneeberg; The C. V. Mosby Company, St. Louis, 1970, $22.50, 440 pages.

A well qualified author and eight contributing authors have efficiently dealt with all of the major endocrine problems as adequately as it is possible to do. The complexities of the numerous chemochemicals that are involved in endocrinology and the biogenesis of many of these have been compounded by the extensive use of the abbreviation system. Fortunately an appendix of these has been included; but for the usual reader a complete spelling of each of these abbreviations would, in all probability, provide a smoother flow of thought than is possible for one who must keep clearly in mind the meaning of a dozen or so acronyms for each chapter, and a new set for the next chapter.

The book is beautifully bound, adequately illustrated, nicely indexed and a credit to the author. For the endocrinologist it is an up-to-date masterpiece. For the practicing physician it is an excellent reference.

Pre-Sate®
(chlorphentermine HCl)

CAUTION: Federal law prohibits dispensing without prescription.

Indications: Pre-Sate (chlorphentermine hydrochloride) is indicated in exogenous obesity, as a short term (*i.e.*, several weeks) adjunct in a regimen of weight reduction based upon caloric restriction.

Contraindications: Glaucoma, hyperthyroidism, pheochromocytoma, hypersensitivity to sympathomimetic amines, and agitated states. Pre-Sate (chlorphentermine hydrochloride) is also contraindicated in patients with a history of drug abuse or symptomatic cardiovascular disease of the following types: advanced arteriosclerosis, severe coronary artery disease, moderate to severe hypertension, or cardiac conduction abnormalities with danger of arrhythmias. The drug is also contraindicated during or within 14 days following administration of monamine oxidase inhibitors, since hypertensive crises may result.

Warnings: When weight loss is unsatisfactory the recommended dosage should not be increased in an attempt to obtain increased anorexigenic effect; discontinue the drug. Tolerance to the anorectic effect may develop. Drowsiness or stimulation may occur and may impair ability to engage in potentially hazardous activities such as operating machinery, driving a motor vehicle, or performing tasks requiring precision work or critical judgment. Therefore, such patients should be cautioned accordingly. Caution must be exercised if Pre-Sate (chlorphentermine hydrochloride) is used concomitantly with other central nervous system stimulants. There have been reports of pulmonary hypertension in patients who received related drugs.

Drug Dependence: Drugs of this type have a potential for abuse. Patients have been known to increase the intake of drugs of this type to many times the dosages recommended. In long-term controlled studies with high dosages of Pre-Sate, abrupt cessation did not result in symptoms of withdrawal.

Usage In Pregnancy: The safety of Pre-Sate (chlorphentermine hydrochloride) in human pregnancy has not yet been clearly established. The use of anorectic agents by women who are or who may become pregnant, and especially those in the first trimester of pregnancy, requires that the potential benefit be weighed against the possible hazard to mother and child. Use of the drug during lactation is not recommended. Mammalian reproductive and teratogenic studies with high multiples of the human dose have been negative.

Usage In Children: Not recommended for use in children under 12 years of age.

Precautions: In patients with diabetes mellitus there may be alteration of insulin requirements due to dietary restrictions and weight loss. Pre-Sate (chlorphentermine hydrochloride) should be used with caution when obesity complicates the management of patients with mild to moderate cardiovascular disease or diabetes mellitus, and only when dietary restriction alone has been unsuccessful in achieving desired weight reduction. In prescribing this drug for obese patients in whom it is undesirable to introduce CNS stimulation or pressor effect, the physician should be alert to the individual who may be overly sensitive to this drug. Psychologic disturbances have been reported in patients who concomitantly receive an anorexic agent and a restrictive dietary regimen.

Adverse Reactions: Central Nervous System: When CNS side effects occur, they are most often manifested as drowsiness or sedation or overstimulation and restlessness. Insomnia, dizziness, headache, euphoria, dysphoria, and tremor may also occur. Psychotic episodes, although rare, have been noted even at recommended doses. **Cardiovascular:** tachycardia, palpitation, elevation of blood pressure. **Gastrointestinal:** nausea and vomiting, diarrhea, unpleasant taste, constipation. **Endocrine:** changes in libido, impotence. **Autonomic:** dryness of mouth, sweating, mydriasis. **Allergic:** urticaria. **Genitourinary:** diuresis and, rarely, difficulty in initiating micturition. **Others:** Paresthesias, sural spasms.

Dosage and Administration: The recommended adult daily dose of Pre-Sate (chlorphentermine hydrochloride) is one tablet (equivalent to 65 mg chlorphentermine base) taken after the first meal of the day. Use in children under 12 not recommended.

Overdosage: Manifestations: Restlessness, confusion, assaultiveness, hallucinations, panic states, and hyperpyrexia may be manifestations of acute intoxication with anorectic agents. Fatigue and depression usually follow the central stimulation. Cardiovascular effects include arrhythmias, hypertension, or hypotension and circulatory collapse. Gastrointestinal symptoms include nausea, vomiting, diarrhea, and abdominal cramps. Fatal poisoning usually terminates in convulsions and coma.

Management: Management of acute intoxication with sympathomimetic amines is largely symptomatic and supportive and often includes sedation with a barbiturate. If hypertension is marked, the use of a nitrate or rapidly acting alpha-receptor blocking agent should be considered. Experience with hemodialysis or peritoneal dialysis is inadequate to permit recommendations in this regard.

How Supplied: Each Pre-Sate (chlorphentermine hydrochloride) tablet contains the equivalent of 65 mg chlorphentermine base; bottles of 100 and 1000 tablets.

Full information available on request.

WARNER-CHILCOTT
Division, Warner-Lambert Company
Morris Plains, New Jersey 07950

for the practical generation

Pre-Sate®

(chlorphentermine HCl)

the trend is toward our kind of anorectic

Not a controlled drug under the Comprehensive Drug Abuse Prevention and Control Act

- low potential for abuse
- less CNS stimulation than with d-amphetamine or phenmetrazine

Effective anorectic adjunct to your program of caloric restriction and diet re-education

- weight loss comparable to d-amphetamine and phenmetrazine, superior to placebo
- convenient one-a-day dosage

GP-21-B/W

Pre-Sate® (chlorphentermine HCl)...the increasingly practical appetite suppressant

When you select this familiar antibiotic for IV infusion you have available a broad dosage range that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

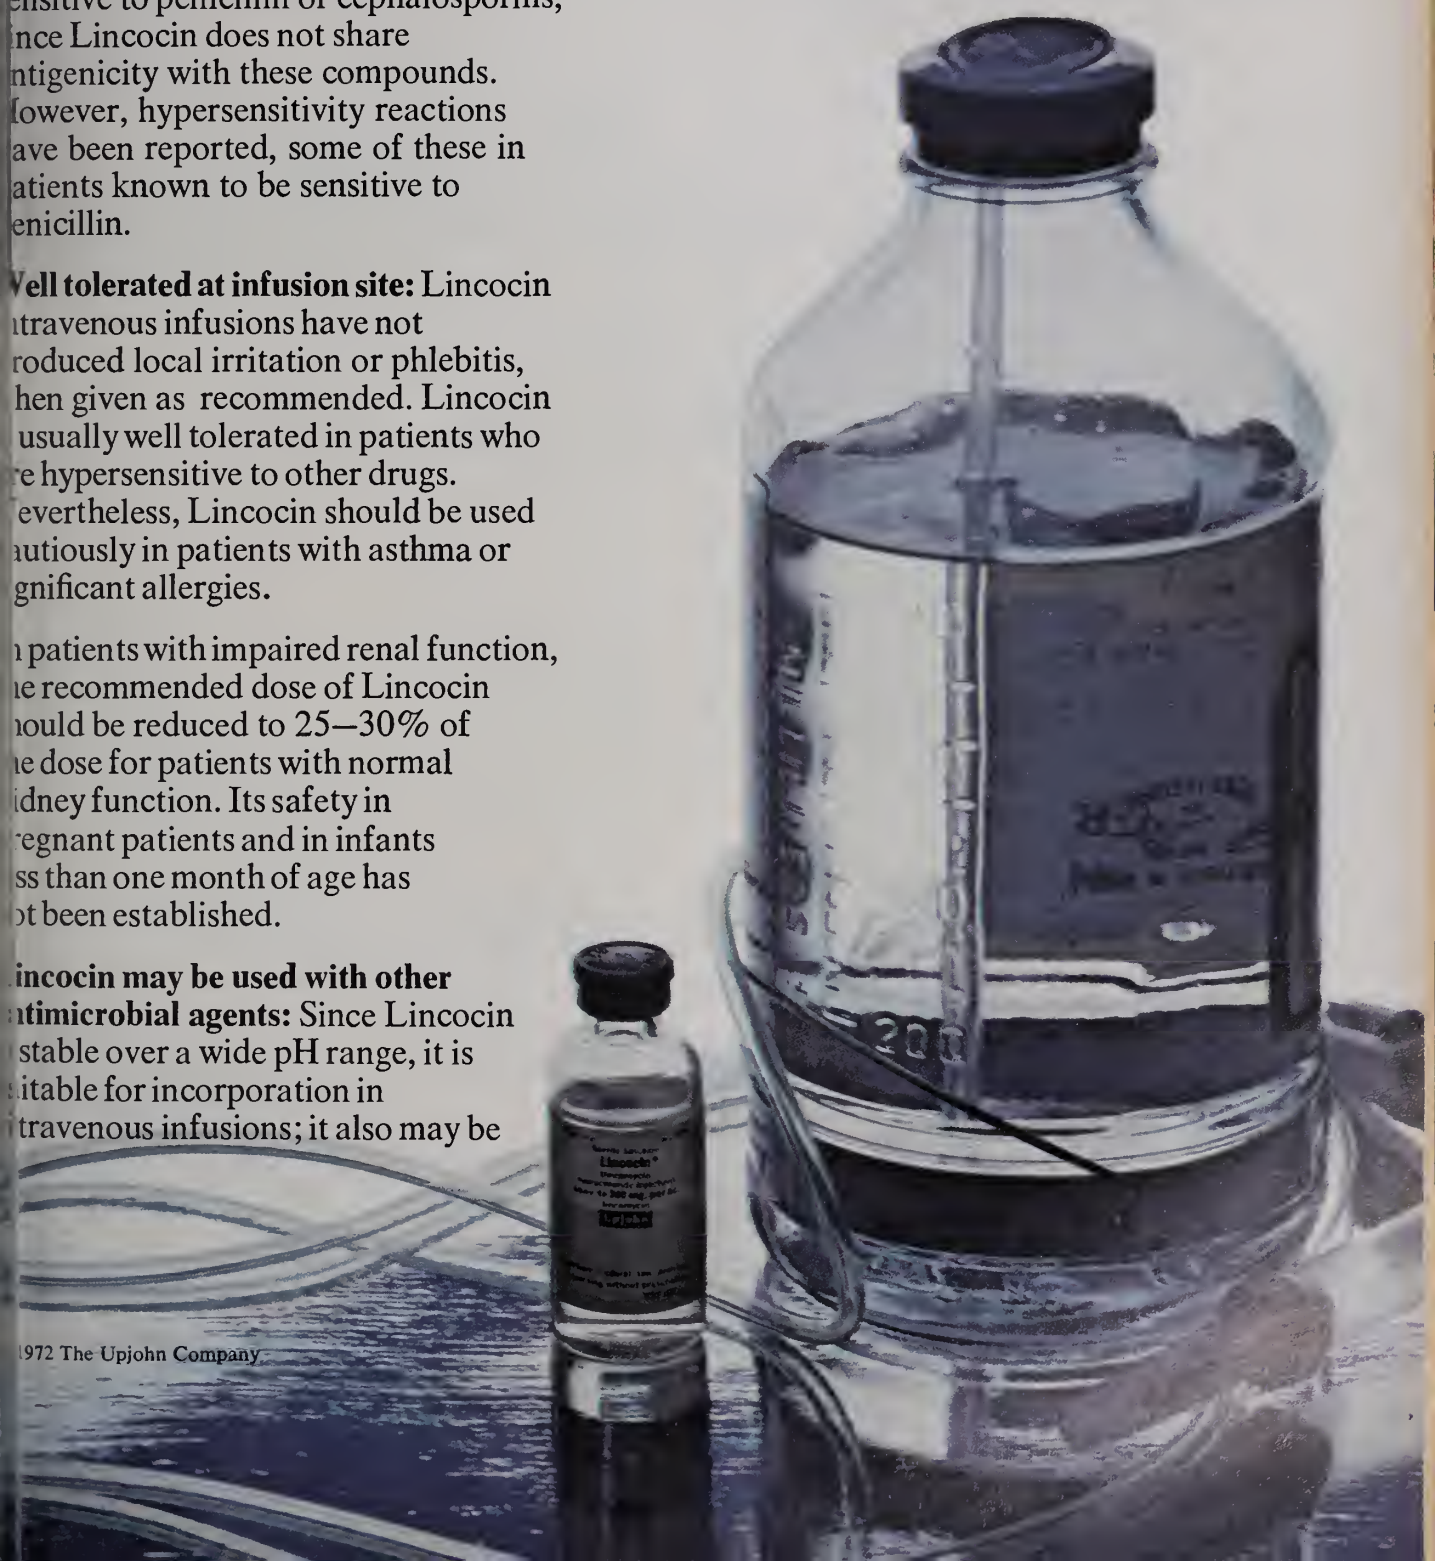
In usual IV doses, Lincocin (lincomyci hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water. But when 4 grams or more per day is given, Lincocin should be diluted in nc less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

nfections caused by susceptible strains
f pneumococci, streptococci, and
taphylococci, including penicillin-
esistant strains. Staphylococcal strains
esistant to Lincocin (lincomycin
ydrochloride, Upjohn) have been
ecovered. Before initiating therapy,
ulture and susceptibility studies should
e performed. Lincocin has proved
aluable in treating patients hyper-
ensitive to penicillin or cephalosporins,
nce Lincocin does not share
ntigenicity with these compounds.
lowever, hypersensitivity reactions
ave been reported, some of these in
atients known to be sensitive to
enicillin.

Vell tolerated at infusion site: Lincocin
travenous infusions have not
roduced local irritation or phlebitis,
hen given as recommended. Lincocin
usually well tolerated in patients who
e hypersensitive to other drugs.
evertheless, Lincocin should be used
autiously in patients with asthma or
gnificant allergies.

patients with impaired renal function,
ie recommended dose of Lincocin
ould be reduced to 25–30% of
ie dose for patients with normal
idney function. Its safety in
egnant patients and in infants
ss than one month of age has
ot been established.



incocin may be used with other
ntimicrobial agents: Since Lincocin
stable over a wide pH range, it is
itable for incorporation in
travenous infusions; it also may be
administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

1972 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn)

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) *is* indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatm*Skin and mucous membranes*—Skin rash urticaria, vaginitis, and rare instances of foliative and vesiculobullous dermatitis h been reported. *Liver*—Although no direct lationship to liver dysfunction is establish jaundice and abnormal liver function t (particularly serum transaminase) have b observed in a few instances. *Cardiovascu* —Instances of hypotension following pa teral administration have been report particularly after too rapid IV adminis tion. Rare instances of cardiopulmonary rest have been reported after too rapid administration. If 4.0 grams or more adm istered IV, dilute in 500 ml of fluid administer no faster than 100 ml per h *Special senses*—Tinnitus and vertigo h been reported occasionally. *Local react* —Excellent local tolerance demonstrate intramuscularly administered Linco (lincomycin hydrochloride). Fracture Conference

Nonunions of the Humeral Shaft*

Darrell E. Fisher, M.D.:

Previously, fractures of the humeral shaft were discussed in relation to multiple injury, infection, and radial-nerve involvement. The present discussion will consider such fractures only in relation to the problems of nonunion itself. Prior to 1940, humeral-shaft fractures accounted for the greatest number of nonunions in long bones. In 1940 Caldwell reported the use of the hanging cast in this fracture, which he had used since 1933. This technique revolutionized previous cast techniques; nonunion of the humerus no longer was as difficult a problem. Stewart and Hundley[1] from the Campbell Clinic reported on 223 humeral-shaft fractures, including all types of fractures and associated injuries, and found only five with nonunion. In these cases, nonunion was considered to be due to distraction by hanging casts that were too heavy. They recommended appropriate hanging casts for all humeral fractures regardless of their level.

Nonunion of any long bone can be a problem, not only in definition and diagnosis but also in treatment. Nonunion is essentially a halt in the normal process of repair in fracture healing. It is often considered in relation to time alone; whereas, in fact, it is a pathologic change. Frequently, a delayed union is considered a nonunion, when actually the processes of healing are proceeding by x-ray and clinical assessment, even though more slowly than usual. Nonunion may become apparent at any time (Table 1). Clinical

TABLE 1

Symptoms and Signs of Nonunion in Femoral-Shaft Fractures

Clinical	X-ray	Histologic
Pain	Defect in continuity	Interposed fibrosis
Edema	Sclerosis of bone ends	No trabecular bridge
Local temperature	"Rounding"	Necrotic bone ends
Motion or crepitus	"Mushrooming"	Pseudarthrosis
Conduction of vibration	"Tapering"	
	Medullary occlusion	
	Stress test motion	
	Serial films	

TABLE 2

Factors Related to Fracture Union and Nonunion

Treatment Factors	Inherent Factors
Reduction	Site (cortical or cancellous)
Immobilization	Type (oblique, spiral, transverse)
Distraction	Comminution or bone loss (or both)
Compression	Compounding
Surgical intervention	Infection
	Interposition of soft tissue
	Blood supply
	Local pathologic changes
	Age of patient
	General condition

examination often indicates nonunion, but roentgenography is the usual means of diagnosis. Of course, histologic material will confirm the diagnosis. All degrees of union are seen; and in delayed union the patient is frequently treated before frank nonunion develops. Numerous factors determine whether or not fractures unite (Table 2). There is obvious connection between the treatment factors and the inherent factors.

The time of clinical and x-ray union in the humerus was illustrated in a series of 87 patients. In 10 weeks, 75% of the patients had clinical union and most had x-ray union. Several groups have studied the causative factors of nonunion in fractures of the shaft. In a series of 2,700 shaft fractures of all kinds at the Research Hospital in Illinois,[2] the most common factors in 127 nonunions were inadequate initial reduction, interposition of soft tissue, distraction, and improper surgery. Mnaymneh, Smith-Petersen, and Aufranc[3] analyzed 47 humeral-shaft nonunions at Massachusetts General Hospital. The order of frequency of fractures affected was: (1) those in the middle third of the shaft, (2) those that were either compounded or comminuted (or both), and (3) those that had had primary open reduction. They believed that all three of these fracture types were related to blood supply.

In this respect, Laing[4] did a definitive study on the blood supply to the adult humerus, using injections of barium sulfate in adult cadavers (ages 30 to 80 years). In this group of 30 cadavers he found that a single artery supplied the nutrient vessel in 28 and that two or more smaller arteries supplied the bone nutrient vessels in the other two. The nutrient artery was a direct branch of the brachial artery in more than 20 cases and entered the medial and anterior portion of the shaft at the junction of the middle and lower thirds in nearly all cases. This work emphasizes the dangers of ischemia after fracture in the middle and distal thirds not only during the fracture itself but also during any surgery performed in this region. Laing concluded that blood supply is the single most critical factor in relation to nonunion of the humerus.

In 1935, Ghormley and Mroz[5] reported the results in 341 cases of humeral-shaft fracture seen at the Mayo Clinic from 1926 to 1930, prior to the time of the use of the hanging cast. Fractures at all levels were represented. They believed that the most common causes of nonunion were inadequate fixation and too brief periods of immobilization. They found that the humeral shaft was the most difficult of all long bones to hold and to fix initially. Watson-Jones[6] believes that inadequate type or length of immobilization is the cause of all nonunions. I am not so sure we would agree with him.

Case 1

Dr. Fisher:

A 50-year-old nurse, on March 25, 1968, fell down three steps and suffered a slightly comminuted spiral fracture of the right humerus. There was no other attendant injury. She was treated with a hanging cast for 10 weeks and nonunion was diagnosed from clinical and x-ray evidence.

In July 1968, she came to the Mayo Clinic, at which time she had pain and crepitation, and x-ray evidence of nonunion (Figure 1*A*). On July 16, 1968, through an S-curved incision, the pseudarthrosis was excised, medullary canals were reamed, and an onlay tibial graft, 1½ by 9 cm, was held with six screws. The fracture itself was fixed with two screws (Figure 1*B*). Cancellous chips of bone were added and a well-fitted Velpeau dressing was used. The dressing was changed weekly for the next couple of months, during which time she had severe, acute thrombophlebitis. By October—three months after internal fixation—the roentgenogram showed evidence that the grafts were incorporating. Her elbow and her shoulder

were developing motion. The last film taken four months after internal fixation showed sound healing (Figure 1*C*). Her elbow could move from 50° to 150°, and she had only minimal stiffness of her shoulder.

John C. Ivins, M.D.:

Could we see the initial before-treatment x-ray? Did you describe the general appearance of this patient as essentially round, not too fat, but a lot too short? You can see from this x-ray (Figure 1*A*) that everything about her is big and fat. I would like to know how some of my colleagues would initially treat a fracture like this in a patient with a similar body configuration. The reason I am asking the question is that, in such a fracture, I have never been able to use a hanging cast when the patient had a body build like this.

Mark B. Coventry, M.D.:

I would think you could. Why not?

Dr. Ivins:

The hanging cast does not hang properly because of the patient's body build.

James H. Dobyns, M.D.:

You can move the breast out of the way, or you can build a little shelf.

Dr. Coventry:

But you have some abduction because of the breast and you have gravity working for you.

Dr. Fisher:

In this type of situation, Caldwell recommended the use of the abduction splint or sometimes a well-applied spica cast because of the body configuration.

Einer W. Johnson, Jr., M.D.:

Is it more a problem of body configuration or of the proportion of fat versus muscle in this hanging arm? If the weight of the forearm is greater than the power of the muscles in the upper arm, then the hanging cast will fail because these muscles are overpulled and distraction of the fragments will occur. The breast does not put as much distracting force on the fracture as the weight of the forearm does.

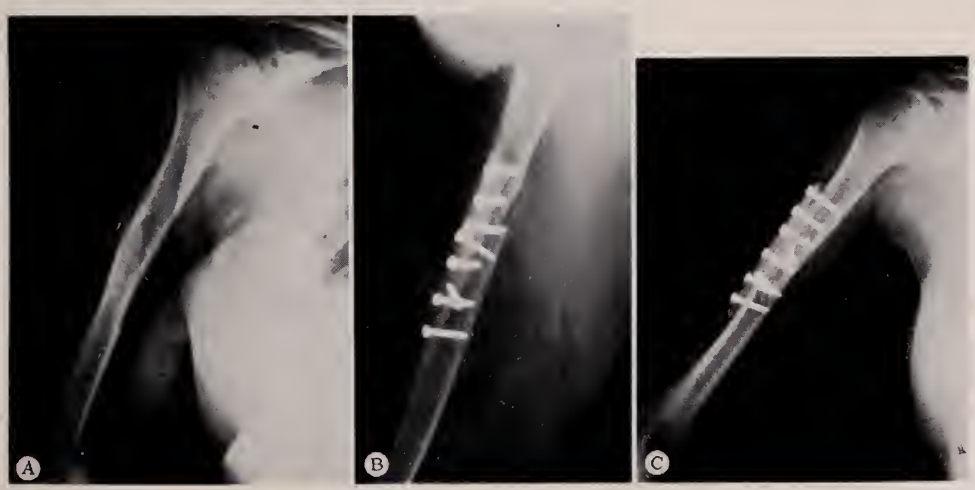

Fig. 1—(Case 1). *A*, Nonunion of comminuted spiral shaft fracture 14 weeks after initial treatment in hanging cast. *B*, Postoperative internal fixation with tibial onlay graft and eight screws. *C*, Clinical and x-ray union four months after internal fixation.

Dr. Ivins:

As far as I am concerned, the problem is a mechanical one. It does not concern the breast only. When this patient, like all people with this type of body configuration, walks down the street, she holds her arms out at her sides like wings, because her arms simply will not come down. It has been my experience that, when these patients are treated by a hanging cast, they have intertrigo-like skin problems that are worse than the initial fracture.

Richard S. Bryan, M.D.:

I have treated one or two such patients with only a plaster splint and a Velpeau because, as Dr. Johnson has said, the arm is just too heavy.

Case 2

Dr. Fisher:

A 38-year-old lady, in an altercation with her husband on November 29, 1967, suffered a fracture of the distal third of the humerus. It was electively fixed internally on the day of injury with two small, threaded wires and some external support. Three months later without evidence of healing, the fracture was treated with two stainless steel screws in a similar manner; a cast and sling were used thereafter for six months. The following July—eight months after her injury— when seen at another clinic, she had extensive osteoporosis, Sudeck's atrophy involving her hand and arm (with considerable pain), and many skin changes. She came to the Mayo Clinic for another opinion 10 months after injury. At that time she had severe pain, 10° of motion in the elbow, 20° in the shoulder, and a history of an allergy to nearly all metals, including gold and silver (Figure 2*A* and *B*). She was very difficult to handle throughout the entire course of treatment, as was her husband, who added to an already serious problem.

Dr. Ivins:

Will someone comment about the initial treatment of a fracture like this? This is a closed fracture with no soft-tissue injury and a very short distal humeral fragment. What is the proper initial treatment for this fracture? Is this a fracture that can be treated by a hanging cast?

Dr. Dobyns:

I seldom use a hanging cast. I might use a Velpeau dressing or a splint. I would want to make sure that I approximated the fragments and did not distract them.

Dr. Ivins:

On the assumption that there were no soft-tissue injuries or other extenuating circumstances, would you use open reduction?

Edward D. Henderson, M.D.:

I think that you can open it if you have some justification, but if you did an open reduction, you would have to apply adequate internal fixation—with a plate for example.

Dr. Ivins:

This case, like many, was not simply one of a fracture. There were extenuating circumstances. Therefore one must be reserved in criticizing the previous treatment. This fracture was produced by physical combat between man and wife, and after the doctor had started the treatment at another institution, there was additional physical combat.

Dr. Coventry:

Still, two Kirschner wires are not adequate internal fixation under any circumstances, extenuating or otherwise.

Dr. Fisher:

On August 19, 1968, nine months after injury, the two screws were removed via the old posterior incision. No reaction was found around these screws. The pseudarthrosis was excised, the ends were squared to bleeding bone, and a four-hole compression plate with strip grafts of iliac bone was applied (Figure 2*C*).

Dr. Ivins:

In looking at this x-ray, keep in mind that the shoulder was completely stiff and that the elbow was virtually stiff.

Dr. Fisher:

Three months after the compression plate was applied, after extensive ef-

Fig. 2—(Case 2). *A* (anteroposterior), and *B* (lateral), Nonunion 10 months after injury and two unsuccessful attempts at internal fixation. *C*, Postoperative internal fixation with four-hole compression plate and autogenous onlay iliac bone grafts. *D* (anteroposterior), and *E* (lateral), Clinical and x-ray union eight months after bone grafting and compression fixation.

forts at physical therapy, and after psychiatric therapy for both husband and wife, the elbow had motion from 50 to 90°, but the shoulder was still almost completely stiff. The patient had considerable pain in the upper extremity, and this was a distressing problem. Four and a half months later, with therapy, her hand had progressed to near normal, as had her wrist. The elbow now had 65° of motion, and shoulder motion was at least noticeable. Films on April 23, 1969, eight months after internal fixation, showed much better range of motion (Figure 2*D* and *E*). She was able to swim and loosen up the shoulder. Her joints were painless, and x-rays showed bridging of the graft and early trabecular bone crossing the osteotomy site.

Dr. Ivins:

We obviously lost a lot of position at the operative site. Her arm did not look as bad as the x-ray indicates, however. The arm had an acceptable appearance. Would anyone care to comment about the initial treatment? Just forget the other extenuating circumstances, the stiff shoulder, and the elbow still in moderate extension.

Dr. Coventry:

The case speaks for itself. You succeeded. That is the best way to handle it.

Dr. Ivins:

I would not know how else to handle this case. By virtue of her other operation, she had a lot of scar tissue. There was not much to work with because of the short distal fragment. The short plate was mortised into the distal fragment, which accounted for some loss of firm fixation, and thus the angulation. But I actually think her loss of position, as evident on the x-rays, is more a product of our efforts to try to get motion back into her shoulder, elbow, and hand than anything else.

Dr. Dobyns:

How soon did you start her on active motion?

Dr. Ivins:

I do not know exactly, but about the end of the seventh week, I think.

Anthony J. Bianco, Jr., M.D.:

Initially, I would have treated it with a Velpeau dressing plus a collar and cuff.

Dr. Ivins:

I think that is a good form of treatment, assuming that you have a cooperative patient. She was a woman of very spare build. I think she could have been treated in many nonsurgical ways, by the immobilization you have just described or perhaps by a hanging cast or simply by a Velpeau dressing. I would have given it a try.

Dr. Bianco:

You would not have opened the fracture originally?

Dr. Ivins:

No, I would not have.

Dr. Fisher:

The question of order of treatment regarding the stiffness of the joints in trying to maintain or return some motion and general health to the extremity before treatment of nonunion is one that challenges everyone. That is why

this woman came to our clinic. Previously all efforts were made to restore motion of the wrist, hand, elbow, and shoulder before an effort to treat the nonunion was made.

Case 3

Dr. Fisher:

A 40-year-old fertilizer plant manager was in an automobile accident in October 1965. He suffered fractures of the shafts of both humeri. There were no other injuries. The right humeral-shaft fracture was treated with a Rush pin in the hope of gaining early motion and function. The left humeral fracture was treated by a hanging cast. As you might surmise, the left humerus healed completely in two months, while the right did not unite. Eleven months later, the nonunion was treated by removal of the rod, application of iliac grafts, and use of a long-arm cast for fixation. Fourteen months after fracture, a sliding bone plate and iliac grafts were done. The patient came to our clinic almost three years after his original injury, with good range of motion at the shoulder, arm, hand, and wrist. It was now 23 months since his last operation. He has now had three open attempts to gain union of this bone (Figure 3*A*).

Dr. Ivins:

What about the other humerus?

Dr. Fisher:

The left humerus healed very well and was stable in two months. Through the old lateral incision scar, the right humeral nonunion was exposed on November 14, 1968. The broken plate and four screws were removed. A pseudarthrosis was excised. The ends were again squared back to bleeding bone with a handsaw, and a six-hole compression plate with strips and chips of added iliac bone was used (Figure 3*B*). Velpeau dressings were used initially, and the patient went home in a long-arm cast.

Dr. Ivins:

Can anyone criticize the treatment? To summarize, there was no radial nerve palsy, the bone was exposed through the old scar of the patient's three previous operations, the pseudarthrosis was excised, the bone ends were

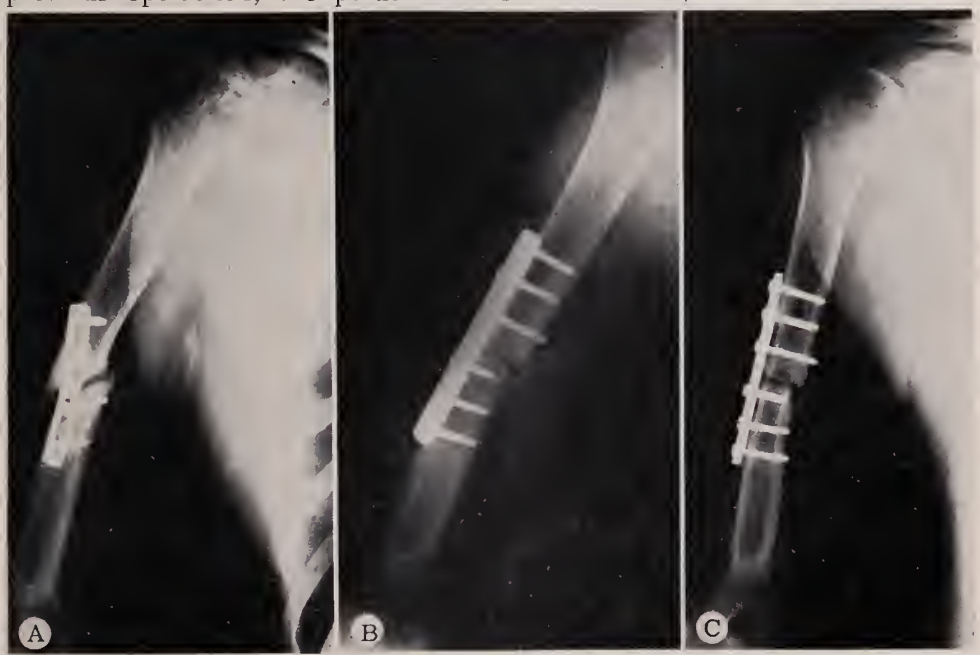

Fig. 3—(Case 3). *A*, Established nonunion and pseudarthrosis three years after fracture and three unsuccessful attempts at internal fixation. *B*, Postoperative excision of pseudarthrosis and compression fixation, with autogenous iliac bone grafts. *C*, Persistent nonunion five months after the fourth internal fixation.

squared off back to bleeding bone, and a six-hole compression plate was applied.

Dr. Coventry:

I would use a spica cast instead of a hanging cast.

Dr. Johnson:

How much shortening does this require, about 2 cm?

Dr. Ivins:

I would think almost 3 cm of total shortening.

Dr. Henderson:

I think that, if you are going to do open reduction and fixation of a fracture of the humerus, good internal fixation should be sufficient. The problem is that, in many cases, internal fixation is not adequate. I know of three patients who have been treated the same way for the same reason, and the results have been very successful. There is the problem of the compression plate. Does it really work because it supplies compression or because it is good internal fixation? Mechanically, these devices are made so that there is good, rigid internal fixation. I think that if you are going to do internal fixation, it must be good and rigid—this is the real problem.

Dr. Ivins:

In this situation, disregarding whether or not compression has any value, do you believe that a single, heavy six-hole plate gives adequate fixation?

Dr. Henderson:

I would feel a lot safer with two plates at right angles to each other.

Dr. Fisher:

The patient's x-ray was taken on April 23, 1969, five months after the compression plate was applied (Figure 3*C*). He had maintained good motion but still had pain.

Dr. Ivins:

He still had pain at the fracture site, and no evidence of union after five months.

Dr. Fisher:

Consultation with Dr. Ivins' colleagues was obtained, and opinions varied.

Dr. Ivins:

After four operations, the patient had a normal shoulder, elbow, wrist, and hand and normal fingers. He had no radial-nerve problem; the condition of his skin was good. He has had four operations and now has a six-hole plate and six screws, with evidence of nonunion that is more obvious now than it was in the early postoperative period. What should the next move be?

Dr. Henderson:

Is there a reaction around the screws?

Dr. Fisher:

I tried to trace any motion or any screw reaction through on the intervening x-rays and I could not see any. You can see how the humerus had been reamed distally before.

Dr. Coventry:

Right where the artery is, as you pointed out earlier, I would put in iliac onlay grafts medially and wait it out. I would not trust this plate and six

screws and osteoporotic bone to take care of all the torsional rotation forces. Dr. Henderson says that this is usually sufficient, but not always. My experience is somewhat different.

Dr. Ivins:

Are there any indications to remove the plate?

Dr. Coventry:

No. I would add onlay grafts.

Dr. Dobyns:

In orthopedic training, we spend most of our time discussing bone mechanics and mechanical stability of the fracture, which is important. But there are other things to think of. We should mention the soft-tissue environment, which I think is very important in the development of a nonunion. Maybe nobody agrees, but I think you need a nice, clean bed of soft tissue to adequately treat any nonunion by surgical means.

Dr. Ivins:

I agree. This is extremely important. By way of summary, I would like to mention the following points: (1) Often the least treatment produces the best results in fractures of the humeral shaft. (2) Open reduction should not be undertaken lightly and, if done, should be augmented by good, rigid internal fixation. (3) With proper treatment and good rehabilitation, the average closed humeral-shaft fracture should produce minimal disability.

WANTED NOW: General Practitioner and a Surgeon to join our three-doctor Clinic in Northwest Wisconsin Resort, Forest and Retirement Area Town of 2,400 with a patient population of 25,000. Fully equipped modern Clinic building, with new accredited 50-bed Hospital and 50-bed extended care nursing home. Deer, ducks, partridge and fish 5 minutes away. Generous salary commensurate with training and experience the first year, then full partnership. Brochure with maps and photos upon request. Call collect or write L. J. Olson, M. D., Spooner Clinic Ltd., Spooner, Wisconsin 54801, telephone 715-635-2151.

AVAILABLE—Young married G.P. with some surgical experience. Deferment not needed. Write Minnesota Medicine, 462, 375 Jackson St., St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul 55101.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

GENERAL PRACTITIONER to join young 5 man family practice group. College town of 7,000 serving approximately 20,000 population. Accredited hospital with specialist consulting staff. 30 miles from St. Paul-Minneapolis, Minnesota. Contact R. M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin 54022. Phone (715)-425-5322.

GENERAL PRACTITIONER needed for an extremely busy rural practice in Northern Minnesota. Excellent hospital and clinic facilities. Starting salary of $25,000.00 with possible early partnership. Write MINNESOTA MEDICINE, Box 466, 375 Jackson, St. Paul, Minn.

GENERAL PRACTITIONER needed by three-man group with downtown and suburban Southdale office. Write MINNESOTA MEDICINE, Box 464, 375 Jackson, St. Paul 55101.

FOR SALE—White Bear Lake, Minn. Commercial building, air conditioned, three (3) examination rooms, lab, private office, receptionist office, reception room. All steelcase furniture included. Phone 429-2616, 426-3465.

EXCELLENT OPPORTUNITY for G.P. or Surgeon in progressive southern Minnesota town of 800. Large rural trade area. Stable economy. Good school system, 18 hole golf course and clubhouse, swimming pool, parks and playgrounds. Near Rochester and Austin. Building and equipment available for purchase or rent. Inquire Farmers State Bank of Adams, Minn., telephone 507-582-3448.

STUDENT HEALTH SERVICE—Full time staff position available immediately at Mankato State College, Mankato, Minn. Salary $25,000 1 month vacation plus holidays and other fringe benefits. Dr. Harry Brauer M.D., Student Health Service, Mankato, Minn. 56001. 507-389 2726.

UNIQUE CHALLENGE—THE FAMILY PRACTICE DEPARTMENT of St. Paul-Ramsey Hospital needs an experienced general practitioner. If you want to promote the concepts of general practice and participate actively in the Family Medicine movement, this is for you. This program enjoys the cooperation of all 19 departments at St. Paul-Ramsey and its 50 full-time specialists. It has solid funding and represents a unique blend of patient-oriented care, university academic affiliation and social involvement. For further details regarding academic appointments, salaries and fringe benefits of Family Medicine and Community Health, St. Paul-Ramsey Hospital, St. Paul, Minnesota 55101. Telephone: (612) 222-4260, Ext. 616.

INTERNIST WANTED—Thirty-five doctor prepaid multi-specialty group is opening attractive new offices. Excellent earnings and assured advancement in desirable professional environment. Many tax sheltered benefits, good community near downtown. Generous vacation, conference and teaching time. A. F. Anderegg, M.D., Group Health Plan, Inc., 2500 Como Ave., St. Paul, Minn. 55108. Should nongovernment scientists and physicians play a role in drug regulation?

Doctor of Medicine

Herbert L. Ley, Jr.,
M.D., M.P.H., Formerly
Commissioner, F.D.A.
(1968-1969)
Currently Medical Consultant

In order for drug regulation to be effective, participation in the regulatory process from nongovernment physicians and scientists must be encouraged. Without such involvement, there will continue to be a high degree of controversy surrounding any regulations promulgated by the Food and Drug Administration.

There are two areas in which participation and communication by nongovernment physicians and scientists could significantly improve the process of regulation. First, scientists and physicians throughout the country could become involved in consulting relationships with the Food and Drug Administration in important scientific areas while regulatory policies are being evolved. If nongovernment professionals could bring their expertise and experience to bear early in the decision-making process, they would have less reason to criticize the final outcome.

Secondly, practicing physicians, academic physicians, and academic-based scientists could make it their business to comment on proposed regulations appearing in the Federal Register. Ideally, a system could be instituted whereby medical, scientific and technical people could see the Federal Register regularly, and provide the Food and Drug Administration with a body of opinion that has so far gone unheard. The FDA is caught among pressures from industry, Congress, the Presidential Administration and consumers. It should also feel pressures from practicing physicians and scientists.

In order to become more involved in these stages of the drug regulatory process, nongovernment physicians and scientists should begin to exercise their influence through their respective professional organizations,

state and national medical societies, and specialty groups. Logically, a letter from these organizations representing a collective opinion has far greater weight in the regulatory process than individual letters. If the Food and Drug Administration receives opinions from these organizations early, before a regulation gets into the Federal Register, they are in a good position to respond with further study and review. Without such dissenting opinions, there is very little incentive to make changes in proposed regulations.

One instance in which practitioners did influence drug regulatory affairs in this way is the recent controversy that arose over the legitimacy of drug combinations. The strong opinion of practitioners on the value of such medication in clinical practice played a very prominent role in making the Food and Drug Administration modify its rather restrictive policy.

Another way in which practitioners can effectively influence drug regulations is by working with drug manufacturers conducting clinical trials of chemotherapeutic agents. When a drug is rated other than effective it may only mean that there is a lack of controlled clinical evidence as to efficacy. Thus, physicians might offer to conduct clinical studies that could help keep a truly effective drug in the marketplace. The treatment of diseases such as diabetes and angina are areas where the practitioner can aid in clinical studies because patients suffering from these diseases are rarely found in the conventional hospital setting.

By working with ethically and scientifically sound study designs in his everyday practice, the practitioner could begin to play an important part in determining official ratings on drug efficacy.

Nongovernment physicians and scientists and the FDA should also improve their lines of communication to the public. The medical community must develop a voice every bit as loud as that of the consumerists, the press, and others who sometimes criticize without complete information. If not, much of what the medical community *and* federal regulators do will often be represented in simplistic and somewhat misleading terms.

One illustration of the misuse of the media in this regard is the recall of anticoagulant drugs several years ago. This FDA action was given publicity by the press and television that went far beyond its probable importance. The result was a very uncomfortable situation for the practitioner who had patients taking these medications. Since the practitioner and pharmacist had not been informed of the action by the time it was publicized, in most states they were deluged with calls from worried patients.

The practitioner can attempt to solve these problems of inadequate communication in several ways. One would be the creation of a communications line in state pharmacy societies. When drug regulation news is to be announced, the society could immediately distribute a message to every pharmacist in the state. The pharmacist, in turn, could notify the physicians in his local community so that he and the physician could be prepared to answer inquiries from patients. Another approach would be to use professional publications the practitioner receives.

All of this leads back to my opening contention: if drug regulation is to be effective, timely, and related to the realities of clinical practice, a better method of communication and feedback must be developed between the nongovernmental medical and scientific communities and the regulatory agency.

ue

Maker of Medicine

Henry W. Gadsden, Chairman & Chief Executive Officer, Merck & Co., Inc.

In my opinion, it is the responsibility of all physicians and medical scientists to take whatever steps they think are desirable in a law- and regulation-making process that can have far-reaching impact on the practice of medicine. Yet many events in the recent past indicate that this is not happening. For example, it is apparent from drug efficacy studies that the NAS/NRC panels gave little consideration to the evidence that could have been provided by practicing physicians.

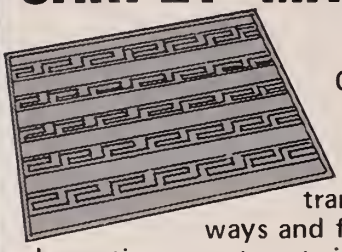
There are several current developments that should increase the concern of practicing physicians about drug regulatory affairs. One is the proliferation of malpractice claims and litigation. Another is the effort by government to establish the relative efficacy of drugs. This implies that if a physician prescribes a drug other than the "established" drug of choice, he may be accused of practicing something less than first-class medicine. It would come perilously close to federal direction of how medicine should be practiced.

In order to minimize this kind of arbitrary federal action, a way must be found to give practitioners both voice and representation in government affairs. Government must be caused to recognize the essentiality of seeking their views. One of the difficulties today, however, is that there is no way for concerned practitioners to participate in the early stages of decision-making processes. They usually don't hear about regulations until a proposal appears in the Federal Register, if then. By that time a lot of concrete has been poured, and a lot of boots are in the concrete.

Physicians in private practice, and particularly clinicians, should press for representation on the advisory committees of the Food and Drug Administration, joining with academic and teaching hospital physicians and scientists who are already serving. Though practitioners may not have access to all available information, the value of their clinical experience should be recognized. Clinicians, for example, rightly remind us that difficulty in *proving* precise effects does not necessarily mean a drug is ineffective.

Unless practitioners are more involved in drug regulations, it will be increasingly difficult for the pharmaceutical industry and scientists elsewhere to make optimal progress in drug development. The benefit/risk ratio must be re-emphasized, and as part of this it must be acknowledged that benefit can come from the judgments of medical science as a whole. Even this concept, unfortunately, is not always accepted in drug regulatory processes. For example, if current medical opinion holds that an excess of total lipids and cholesterol in the blood is probably predisposing to atherosclerosis, and if a drug is discovered which reduces total lipids and cholesterol, the drug ought to be accepted *prima facie* as a contribution to medical science . . . until someone disproves the theory. The sponsor should not have to prove the theory as well as to develop and test the drug.

I feel a major new effort must also be made to erase the feeling of mistrust of medicine and of medicines that seems to be growing in the public consciousness. Triggered primarily by strident announcements in Washington, people are reading and hearing confidence-shaking things almost continuously. Although challenge and awareness are essential to medical advancement, our long-term goal is constructively to build, not destroy. This means strengthening patient-physician relationships based on mutual confidence and trust. And in matters of health policy, it means working toward participatory rather than adversary proceedings—where everyone with an interest and a capacity to contribute has an opportunity to be heard . . . and, if that opportunity is not spontaneously afforded him, he may seek it.



Opinion & Dialogue

What is your opinion, doctor?
We would welcome your comments.

LIBRARY OF THE
COLLEGE OF PHYSICIANS
OF PHILADELPHIA
MAY 15 1972
MDS

...er Festival" — *Murray S. Locke, M.D.*

MAY, 1972

The negative power of undue anxiet
in congestive heart failure...
This man thinks he can no longe
take breathing for granted.

Typical of many patients with congestive heart failure, he also suffers from severe anxiety, a psychic factor that may influence the character and degree of his symptoms, such as dyspnea. His apprehension may also deprive him of the emotional calm so important in maintenance therapy.

Aid in rehabilitation

Specific medical and environmental measures are often enhanced by the antianxiety action of adjunctive Libritabs (chlordiazepoxide). Libritabs can also facilitate treatment of the tense convalescent patient until antianxiety therapy is no longer required. Whereas in geriatrics the *usual daily dosage* is 5 mg two to four times daily, the *initial dosage* in elderly and debilitated patients should be limited to 10 mg or less per day, adjusting as needed and tolerated.

Concomitant use with primary agents

Libritabs is used concomitantly with certain specific medications of other classes of drugs, such as cardiac glycosides, diuretics, antihypertensives, vasodilators and oral anticoagulants, whenever excessive anxiety or emotional tension adversely affects the clinical condition or response to therapy. Although clinical studies have not established a cause and effect relationship, physicians should be aware that variable effects on blood coagulation have been reported very rarely in patients receiving oral anticoagulants and chlordiazepoxide HCl.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Indicated when anxiety, tension and apprehension are significant components of the clinical profile.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

rheumatoid arthritic blowup...

Tandearil® Geigy

oxyphenbutazone NF

tablets of 100 mg.

portant Note: This drug is not a simple analgesic. not administer casually. Carefully evaluate patients fore starting treatment and keep them under close ervision. Obtain a detailed history, and complete ysical and laboratory examination (complete mogram, urinalysis, etc.) before prescribing and at quent intervals thereafter. Carefully select patients, oiding those responsive to routine measures, con- indicated patients or those who cannot be observed quently. Warn patients not to exceed recommended sage. Short-term relief of severe symptoms with smallest possible dosage is the goal of therapy. sage should be taken with meals or a full glass of lk. Patients should discontinue the drug and report mediately any sign of: fever, sore throat, oral ions (symptoms of blood dyscrasia); dyspepsia, igastric pain, symptoms of anemia, black or tarry ols or other evidence of intestinal ulceration or morrhage, skin reactions, significant weight gain or ema. A one-week trial period is adequate. Discon- ue in the absence of a favorable response. Restrict atment periods to one week in patients over sixty. *fications:* Acute gouty arthritis, rheumatoid arthritis, umatoid spondylitis.
ntraindications: Children 14 years or less; senile tients; history or symptoms of G.I. inflammation or eration including severe, recurrent or persistent spepsia; history or presence of drug allergy; blood scrasias; renal, hepatic or cardiac dysfunction; ertension; thyroid disease; systemic edema; matitis and salivary gland enlargement due to the g; polymyalgia rheumatica and temporal arteritis; tients receiving other potent chemotherapeutic ents, or long-term anticoagulant therapy.
rnings: Age, weight, dosage, duration of therapy, stence of concomitant diseases, and concurrent ent chemotherapy affect incidence of toxic reac- ns. Carefully instruct and observe the individual ient, especially the aging (forty years and over) o have increased susceptibility to the toxicity of the g. Use lowest effective dosage. Weigh initially redictable benefits against potential risk of severe, n fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.
Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.
Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia, gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angiitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement.

TA. 8356-9

a new outlook in chronic pain

of moderate to severe intensity

Though Talwin® can be compared to codeine in analgesic efficacy, it is not a narcotic. So patients receiving Talwin for prolonged periods face fewer of the consequences you've come to expect with narcotic analgesics. And that, in the long run, can mean a better outlook for your chronic-pain patient.

Talwin Tablets are:

- **Comparable to codeine in analgesic efficacy:** one 50 mg. Talwin Tablet appears equivalent in analgesic effect to 60 mg. (1 gr.) of codeine. Onset of significant analgesia usually occurs within 15 to 30 minutes. Analgesia is usually maintained for 3 hours or longer.
- **Tolerance not a problem:** tolerance to the analgesic effect of Talwin Tablets has not been reported, and no significant changes in clinical laboratory parameters attributable to the drug have been reported.
- **Dependence rarely a problem:** during three years of wide clinical use, only a few cases of dependence have been reported. In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.
- **Not subject to narcotic controls:** convenient to prescribe – day or night – even by phone.
- **Generally well tolerated by most patients:** infrequently cause decrease in blood pressure or tachycardia; rarely cause respiratory depression or urinary retention; seldom cause diarrhea or constipation. If dizziness, lightheadedness, nausea or vomiting are encountered, these effects tend to be self-limiting and to decrease after the first few doses. (See last page of this advertisement for a complete discussion of adverse reactions and a brief discussion of other Prescribing Information.)

50 mg. Tablets

Talwin®

brand of

pentazocine (as hydrochloride)

the long-range analgesic

a new outlook in chronic pain

of moderate to severe intensity

Contraindications: Talwin, brand of pentazocine (as hydrochloride), should not be administered to patients who are hypersensitive to it.

Warnings: *Head Injury and Increased Intracranial Pressure.* The respiratory depressant effects of Talwin and its potential for elevating cerebrospinal fluid pressure may be markedly exaggerated in the presence of head injury, other intracranial lesions, or a preexisting increase in intracranial pressure. Furthermore, Talwin can produce effects which may obscure the clinical course of patients with head injuries. In such patients, Talwin must be used with extreme caution and only if its use is deemed essential.

Usage in Pregnancy. Safe use of Talwin during pregnancy (other than labor) has not been established. Animal reproduction studies have not demonstrated teratogenic or embryotoxic effects. However, Talwin should be administered to pregnant patients (other than labor) only when, in the judgment of the physician, the potential benefits outweigh the possible hazards. Patients receiving Talwin during labor have experienced no adverse effects other than those that occur with commonly used analgesics. Talwin should be used with caution in women delivering premature infants.

Drug Dependence. There have been instances of psychological and physical dependence on parenteral Talwin in patients with a history of drug abuse and, rarely, in patients without such a history. Abrupt discontinuance following the extended use of parenteral Talwin has resulted in withdrawal symptoms. There have been a few reports of dependence and of withdrawal symptoms with orally administered Talwin. Patients with a history of drug dependence should be under close supervision while receiving Talwin orally.

In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.

Acute CNS Manifestations. Patients receiving therapeutic doses of Talwin have experienced, in rare instances, hallucinations (usually visual), disorientation, and confusion which have cleared spontaneously within a period of hours. The mechanism of this reaction is not known. Such patients should be very closely observed and vital signs checked. If the drug is reinstituted it should be done with caution since the acute CNS manifestations may recur.

Usage in Children. Because clinical experience in children under 12 years of age is limited, administration of Talwin in this age group is not recommended.

Ambulatory Patients. Since sedation, dizziness, and occasional euphoria have been noted, ambulatory patients should be warned not to operate machinery, drive cars, or unnecessarily expose themselves to hazards.

Precautions: *Certain Respiratory Conditions.* Although respiratory depression has rarely been reported after oral administration of Talwin, the drug should be administered with caution to patients with respiratory depression from any cause, severe bronchial asthma and other obstructive respiratory conditions, or cyanosis.

Impaired Renal or Hepatic Function. Decreased metabolism of the drug by the liver in extensive liver disease may predispose to accentuation of side effects. Although laboratory tests have not indicated that Talwin causes or increases renal or hepatic impairment, the drug should be administered with caution to patients with such impairment.

Myocardial Infarction. As with all drugs, Talwin should be used with caution in patients with myocardial infarction who have nausea or vomiting.

Biliary Surgery. Until further experience is gained with the effects of Talwin on the sphincter of Oddi, the drug should be used with caution in patients about to undergo surgery of the biliary tract.

Patients Receiving Narcotics. Talwin is a mild narcotic antagonist. Some patients previously receiving narcotics have experienced mild withdrawal symptoms after receiving Talwin.

CNS Effect. Caution should be used when Talwin is administered to patients prone to seizures; seizures have occurred in a few such patients in association with the use of Talwin although no cause and effect relationship has been established.

Adverse Reactions: Reactions reported after oral administration of Talwin include *gastrointestinal:* nausea, vomiting; infrequently constipation; and rarely abdominal distress, anorexia, diarrhea. *CNS effects:* dizziness, lightheadedness, sedation, euphoria, headache; infrequently weakness, disturbed dreams, insomnia, syncope, visual blurring and focusing difficulty, hallucinations (see *Acute CNS Manifestations* under WARNINGS); and rarely tremor, irritability, excitement, tinnitus. *Autonomic:* sweating; infrequently flushing; and rarely chills. *Allergic:* infrequently rash; and rarely urticaria, edema of the face. *Cardiovascular:* infrequently decrease in blood pressure, tachycardia. *Other:* rarely respiratory depression, urinary retention.

Dosage and Administration: *Adults.* The usual initial adult dose is 1 tablet (50 mg.) every three or four hours. This may be increased to 2 tablets (100 mg.) when needed. Total daily dosage should not exceed 600 mg.

When antiinflammatory or antipyretic effects are desired in addition to analgesia, aspirin can be administered concomitantly with Talwin.

Children Under 12 Years of Age. Since clinical experience in children under 12 years of age is limited, administration of Talwin in this age group is not recommended.

Duration of Therapy. Patients with chronic pain who have received Talwin orally for prolonged periods have not experienced withdrawal symptoms even when administration was abruptly discontinued (see WARNINGS). No tolerance to the analgesic effect has been observed. Laboratory tests of blood and urine and of liver and kidney function have revealed no significant abnormalities after prolonged administration of Talwin.

Overdosage: *Manifestations.* Clinical experience with Talwin overdosage has been insufficient to define the signs of this condition.

Treatment. Oxygen, intravenous fluids, vasopressors, and other supportive measures should be employed as indicated. Assisted or controlled ventilation should also be considered. Although nalorphine and levallorphan are *not* effective antidotes for respiratory depression due to overdosage or unusual sensitivity to Talwin, parenteral naloxone (Narcan®, available through Endo Laboratories) is a specific and effective antagonist. If naloxone is not available, parenteral administration of the analeptic, methylphenidate (Ritalin®) may be of value if respiratory depression occurs.

Talwin is not subject to narcotic controls.

How Supplied: Tablets, peach color, scored. Each tablet contains Talwin (brand of pentazocine) as hydrochloride equivalent to 50 mg. base. Bottles of 100.

Winthrop Winthrop Laboratories, New York, N. Y. 10016 (1583)

President's Letter

President's Report

THIS PAST YEAR has been both a challenging and rewarding year for me as President of The Minnesota State Medical Association. I have tried to visit as many component medical societies as possible to bring the State Medical Association closer to the Local Medical Society. In reviewing the past year, there were three significant developments.

1. As your president, I served on the Search Committee to recommend candidates for Dean of The Medical School on the main campus. Doctor Neal Gault was chosen. Doctor Gault is an excellent choice. I look forward to continued and improved communications between the medical school faculty and the community physician. I am sure that Doctor Gault has a good understanding of the problems and challenges that are involved in his new job; that he will be a conscientious and capable administrator.

2. The Physicians' Associate Program is emerging as a successful venture. Both the medical student and the community physician are enthusiastic in its support. This is the first program that has provided a year's training outside the Medical School. It has improved communications between the teaching physician and the Medical School. The faculty representative visits the medical student and his preceptor once monthly, and this provides educational opportunities for all the physicians in the community. I endorse this program and expect it to expand in the future.

3. Blue Shield has had many and varied problems for the past several years. For the past two years, Blue Cross has been providing administration and management to Blue Shield. In the past year there has been excellent communications between Richard Crist, the President of Blue Cross and Blue Shield, the Board of Directors of Blue Shield and the Council and officers of your State Medical Association. The meetings have been fruitful in defining and solving difficult problems. One month ago the Board of Directors of both Blue Cross and Blue Shield approved a total merger of the two companies. Ratification of this decision by the corporate bodies of both companies is expected. This will insure the solvency of Blue Shield. With this major development concluded, we can, through continued dialog, begin to solve the many remaining existing problems. This progress was made possible through the diligent work of the Administrative Staff and Board of Directors of both Blue Cross and Blue Shield. The patience and cooperation shown the doctors of Minnesota has been outstanding and with continued efforts, resolution of many existing problems will be accomplished.

I want to thank Harold Brunn and his staff for making my year so pleasant. They are really a great gang. Their efficiency is excellent and their spirit is great.

I want to congratulate Carl O. Rice for his untiring efforts for many years in behalf of MINNESOTA MEDICINE. I hope this issue is a fitting memorial to his efforts.

Robert T. Kelly

President
Minnesota State Medical Association

Think Happy Today...
With Twin City Federal,
You're on your way!

You've got the future lookin' bright,
You've got a good year on the way,
You've got good reason
For thinkin' happy today.

Thinking happy is perhaps the best reason of all for saving money. And Twin City Federal helps you save in many important ways: Generous interest rates, like up to 6% on certificates, and 5% on passbook saving. Daily interest, too. Back of your money is the strength and safety of TCF leadership. For a "think happy" life, start saving. We help you with all our might.

Carl O. Rice, M.D.
Editor-in-Chief
Minnesota Medicine
1961-1971

Carl O. Rice: Editor and Surgeon

"An editor is a surgeon . . . It is he who cuts thousands of words of dead wood, organizes and tightens, reshapes sentences, puts in the grammar and punctuation, and still retains the author's book too, though the author doubts it while the process is going on."—Helen K. Taylor, Editor, Viking Press

THIS IS A tribute to Carl O. Rice.

From 1961 through 1971 he served as Editor-in-Chief of MINNESOTA MEDICINE. He will continue as Editor Emeritus.

I have known Carl six years, long enough to appreciate him but not long enough to understand him, for Carl is a complex man. What I write here I learned from being his friend, working with him on the journal, reading his bibliography and interviewing him for this article.

Start of His Career

In 1929 Carl, three years out of medical school, became the first surgical resident of Owen Wangensteen. Early in residency, he saw a child with an imperforate anus. His problem was to find where the rectum ended. As he held the baby near the x-ray machine, a solution flashed through his mind.

Why not turn the infant upside down? Intestinal gas would rise. By placing a metal disc on the anal dimple, then measuring between gas and disc, he could tell exactly where the rectum ended. Later he and Doctor Wangensteen published this simple concept.[1]

This story gives insight into Carl's mind. He is a *why not* man. Because of this turn of mind he often turns problems upside down, converts conundrums into opportunities, and visualizes dimension others fail to grasp.

Contributions

From 1926 to 1929 Carl served as receiving officer at Hennepin County General Hospital. There he reduced many fractures. These reductions caused much pain. So Carl asked: *"Why not* inject procaine directly into the fracture?"

After two papers on the success of the method,[2,3] a well-known Boston orthopedic man, Doctor Cotton* came West to see a young physician's technique for painlessly reducing fractures.

From 1929 to 1933, while doing his residency (three years at the University of Minnesota, a year at Mayo's, then eight months as a fellow under Professor DeQuervain in Switzerland), Carl concentrated on thyroid disease. Again his original mind came into play. *Why not* look at *all* thyroid glands removed at *all* Twin Cities teaching hospitals—University Hospital, Minneapolis General, and Anker?[4] *Why not* use these specimens to study the "life cycle" of thyroid histology from youth to old age?[5] And in Switzerland, *why not* review a canton's experience with thyroid disease and compare it to Minnesota's?[6] So one thing led to another, and a spate of articles resulted.[7-13]

When Carl returned in 1934 to Minneapolis to practice he quickly learned surgeons do not live by thyroid surgery alone, so he focused on some practical aspects of the surgeon's craft.

One thing that annoyed him was the time required to thread needles in the operating room. He spoke about this to a representative of Ethicon. *Why not* make suture and needle a single functional unit? Indeed, *why not* make a series of these swaged needles—one round, one with a cutting edge, and one for intestinal anastomoses? Today millions of these 803, 805 and 123 Ethicon sutures are used throughout the world.

Postoperative deaths soon took his attention away from needles and sutures. Why did surgery go smoothly for patients, yet they died? The main problem, as he saw it, was postoperative-sustaining metabolism with the right mix of fluids, calories, and nitrogen-building compounds. To do this, a metabolism laboratory was needed. This was formed in 1942 at St. Barnabas Hospital. He would also need a flame photometer to measure electrolytes. This he got in 1948. And, of course, it would help to have a partner who understood such matters.

In 1950 Doctor Jacob Strickler joined him. They wrote a series of papers describing how they

*Trimalleolar fractures are often referred to as "Cotton's fracture."

developed electrolyte mixtures that achieved fluid balance, met caloric requirements, and led to a positive nitrogen balance.[14-24] Baxter Laboratories helped finance these studies and still market some of those fluid mixtures.

Through the years Carl has remained a technical innovator—a man with a different way of doing things. For example, he has described a muscle-splitting cholecystectomy incision;[25] a new approach for repairing hernias;[26] and a new procedure, "adenomammectomy", for removing benign breast lesions and hypertrophied breast tissue.[27]

Adenomammectomy

I shall dwell on the adenomammectomy procedure a moment because it reveals Carl's talents —both literary and technical. First of all, he coined the term "adenomammectomy"— a melliluous but precise word that said what he wanted to say. *Dorland's Medical Dictionary* first listed the word in 1966 and *Stedman's* followed in 1967.

Here's *Dorland's* version:

> "adenomammectory (ad" e - no - mah - mek' - to - me) *adeno - mamma - ektome* excision). Excision of part or all of the glandular tissue of the breast, leaving the fibrous capsule and the underlying skin and subcutaneous tissue."

I asked Doctor H. W. Heupel, Carl's other partner, what was different about this procedure when used as a reduction mammoplasty. He said the adenomammectomy concept showed how Doctor Rice thought three-dimensionally. Most surgeons, faced with a hypertrophied breast, would excise a generous segment of breast and skin, then pull together the remaining breast tissue to cover the defect, perhaps transplanting the nipple in the process. Not Carl. His concept is to remove the tissue from behind, "the base of the mountain", as Doctor Heupel says, thereby letting the breast settle back into its natural contour. A much simpler technique. Besides, the chances of the nipples being symmetrical are much greater. In any case, Doctor Ariel, prominent New York cancer surgeon, thought enough of the procedure to ask Doctors Rice and Strickler to contribute a chapter on it in the book *Progress in Clinical Cancer*.[28]

Writing and Editing

Up to this point, I have not commented on Carl's writing or editing. I shall do so now.

In writing, Carl believes strongly in four things: *Merit, Clarity, Flair,* and *Force.* In other words, if you have a nail to hit, pick a straight true nail, hit it on the head, hit it with style, and hit it hard.

For these reasons, Carl is a tough editor, one who cuts through the tangle to get at the pith. He likes to reduce the basic idea of an article into short sentences and short paragraphs, with subheadings to show the way.

This drive for clarity has resulted in editorial excellence. In 1967 the American Medical Writers Association named *Minnesota Medicine* as the best state medical journal. But his determination has ruffled some feathers too. Which is not surprising. For it is sometimes difficult to say: "Although this is a bad idea, it is also badly written."

As an editor, Carl has also been a gambling man. For instance he has placed his chips on colored cover photographs, betting on the reader's esthetic sense, and on foreign issues, risking that readers would enjoy worldwide contributors. Some gambles he has lost. But, true to character, he has never hedged his bets, nor has he made any side wagers.

I close with a quote from M. Lincoln Schuster, former president and Editor-in-Chief of Simon and Schuster, because I think it sums up Carl's feelings about his ten years as editor:

> "Editing can, and should be, not only a life-enhancing profession, but also a liberal education in itself, for it gives you a privilege of working with the most creative people of your time: authors, educators, world-movers, and world-shakers. For taking a lifetime course for which you would be willing to pay tuition, you are paid, not with dollars, but with intellectual and spiritual satisfactions immeasurable."

Richard L. Reece, M.D.
Minneapolis, Minnesota

Metastatic Intestinal Kultschitzky-Cell Carcinoma (Carcinoid) Diagnosis of by Sternal Bone Marrow Biopsy

EMIL MARO SCHLEICHER, Ph.D.*, DENNIS J. KANE, M.D., Ph.D.† and H. WILHELM HEUPEL, M.D., Ph.D.‡

DEMONSTRATING METASTASES to the bone marrow of an intestinal Kultschitzky-cell carcinoma can be important. Yet, though metastases of this tumor to the marrow have been observed at necropsy, we are not aware of any instance where the diagnosis of metastasis was unequivocally established by sternal marrow biopsy as was the case here.

Case Report

A 59-year-old physical education teacher, was admitted to St. Barnabas Hospital§ on August 7, 1969. Eight months before she was plagued by intermittent explosive diarrhea and lost 24 pounds. For a month she experienced pain between the shoulder blades and in both flanks. She underwent a thyroidectomy 20 years before.

A slight exophthalmos was noted. The patient was emaciated and dehydrated. The abdomen was distended and tender. Bowel sounds were active. There was dullness in the right chest on percussion. Thoracentesis yielded two liters of milky fluid from the right chest cavity. No malignants cells were found.

An intravenous cholecystogram showed a normal gallbladder. A liver scan with Au^{198} was negative. X-ray studies revealed a lower mediastinal mass, prominent mucosal folds in the jejunum, and dilatation of the small bowel. A complete blood count, serum electrolytes, and routine blood chemistry were not remarkable. The serum uric acid was 3.2 mg. percent, and the thyroxine chromatography level 5 mg. percent.

Malignant lymphoma was considered the likely diagnosis.

Because lymphocytic tumors may affect the marrow, a sternal marrow aspiration biopsy was done. This showed metastatic Kultschitzky-cell carcinoma. A laparotomy was performed. A tumor partially obstructed the lower jejunum. The bowel loop containing the primary tumor was fused to a mass over the aorta and vena cava. A jejuno-jejunostomy was performed. Yellow metastases, two to ten millimeters in diameter, studded the liver. These proved to be metastases of a Kultschitzky-cell carcinoma (carcinoid).

The patient received a course of L-phenylalanine mustard (Alkeran) and Prednisone one month after surgery. She died on October 11, 1969 from peritonitis due to gangrene of the invaded small bowel loop. Necropsy showed systemic metastases. Marrow from several sites disclosed metastatic tumor.

Sternal Marrow Biopsy

From the body of the sternum at the level of the second intercostal space, 10 ml. of marrow substance were obtained. One hundred marrow units were separated from the aspirate. The units ranged in size from 0.1 to 1.0 millimeter, and all were of the floating type. Marrow units are anatomical-physiological entities of the marrow organ, and can be individually affected by disease.[1] They were fixed in formolsaline fluid, embedded in paraffin, and serially sectioned, 5 micra thin. Stained with hematoxylin-eosin, the sections were then examined under the light microscope.

Metastatic tumor was detected in one marrow unit.

The tumor consisted of closely packed uniform polyhedral nuclei imbedded in an eosinophilic granular cytoplasm. A lighter staining bar-like area suggesting poorly formed glandular lumina was present within the nodular mass. Figure 1 shows the characteristic histopathology of the tumor in serial section #28. In serial section #39 the tumor presented a distinct glandular structure. The acinus contained a small amount of inspissated amorphous eosinophilic material. (Figure 2).

†Clinical Associate Professor, Internal Medicine, University of Minnesota.
‡Clinical Assistant Professor, Surgery, University of Minnesota.
#The spelling of Kultschitzky's name varies as he was a Russian and probably used Cyrillic lettering. We have adopted R. A. Willis' spelling as authoritative.
§Now The Metropolitan Medical Center, Minneapolis, Minn.

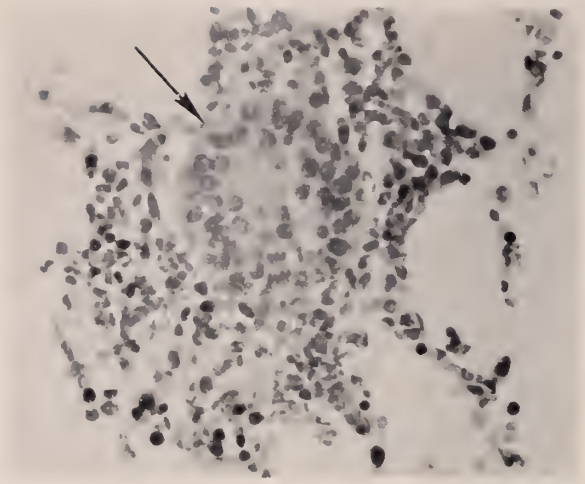

Fig. 1—Section; 5 micra thick of the single marrow unit with tumor metastasis. Arrow points at the solid nodular growth. The histopathology is characteristic of Kultschitzky-cell carcinoma (carcinoid). Hematoxylin-Eosin; x 190.

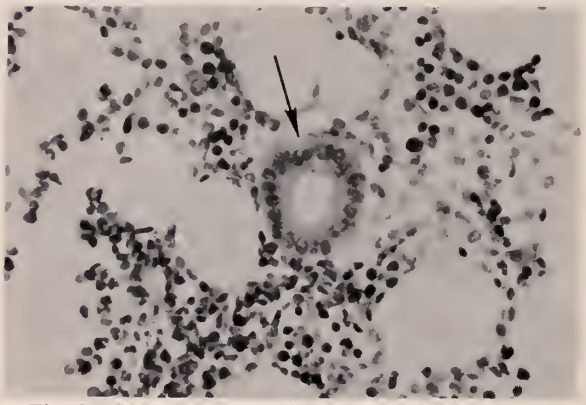

Fig. 2—Same marrow unit as Fig. 1. Arrow points at the glandular structure of the metastasis. Hematoxylin-Eosin; x 190.

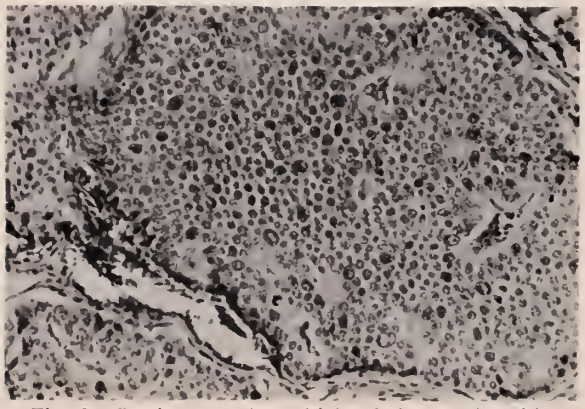

Fig. 3—Section; 5 micra thick of the surgical biopsy of the intestinal tumor. Hematoxylin-Eosin; x 75.

This lesion was interpreted as a metastasis of a Kultschitzky-cell carcinoma (carcinoid).

Figure 3 shows the histopathology of the intestinal tumor, obtained at surgery.

Discussion

Willis[2] does not like the term "carcinoid tumor" because it implies innocence. Carcinoids, especially of the small intestine, can invade and metastasize. Because the tumor arises from the yellow cells of Kultschitzky situated in the crypts of Lieberkuhn, the tumor should be called argentaffin or Kultschitzky-cell carcinoma. In most cases the histopathology of, the tumor is distinct, and identification usually offers no difficulties. The Kultschitzky-cell carcinoma is made up of well defined solid sheets or strands of small closely packed polyhedral cells, with small glandular lumina or distinct acini scattered through the tumor. The more actively growing tumors show various degrees of anaplasia and may escape recognition.

Speirs and Williams[3] advocate resection of the primary tumor if feasible. They conclude, "The prognosis of multiple carcinoid tumors of the small bowel wtih mesenteric metastases remains guarded but seems much more favorable than other types of small bowel malignancy with metastases."

Metastasis to the marrow organ indeed connotes hopelessness in most cancers, but a favorable response to surgery and chemotherapy can at times be hoped for in Kultschitzky-cell carcinomas. Even if bone marrow metastases are found in this tumor, the case for palliative resection and chemotherapy can be argued.

Summary

A Kultschitzky-cell carcinoma of the small bowel was first diagnosed by bone marrow biopsy in a 59-year-old woman. To our knowledge, this has not been reported previously. This tumor responds at times to surgical and medical treatment. Its detection in bone marrow biopsy can be of prognostic and therapeutic consequence.

Granulomatous Peritonitis Induced by Cornstarch Powder

JOHN R. HORNUNG, M.D.* AND ARNOLD J. KREMEN, M.D.*

SINCE THE INTRODUCTION of the rubber glove to surgery, hand powders have accompanied their use in the operating room. Numerous papers documenting iatrogenic disease resulting from these powders in the abdominal cavity have been reported. Two additional cases will be presented.

Case Report

On February 23, 1971, a 43-year-old, white female with symptoms of chronic cholecystitis underwent a cholecystectomy, operative cholangiogram and an appendectomy. At that time exploration of the abdomen was negative. Her postoperative course was uneventful and she left the hospital on the tenth postoperative day. A T-tube was not used.

Subsequent Progress

Four weeks after her surgery she noted the gradual onset of lower abdominal aching pain, more marked on the right. She had several episodes of fever and chills. She denied nausea, vomiting, diarrhea or constipation. She had no urinary symptoms and her menstrual periods were normal. The symptoms persisted and she was readmitted to the hospital on March 31, 1971.

Physical findings revealed marked tenderness to palpation in the lower abdomen, marked rebound tenderness, the suggestion of a mass in the right lower quadrant. Pelvic examination revealed tenderness in the cul-de-sac and in both adnexa. Manipulation of the cervix caused pain.

The initial diagnostic impressions were pelvic inflammatory disease, possibly diverticulitis or granuloma of the cecum subsequent to her appendectomy.

Laboratory Examination

Hgb. 14.0, WBC 10,300 with 74 neutrophils to 12,500 with 79 neutrophils and six eosinophils, sedimentation rate 56 → 80, Na, Cl, K, HCO_3, urinalysis, serum proteins, Ca + +, PO_4, cholesterol, glucose, BUN, creatinine, uric acid, bilirubin, alkaline phosphatese, LDH and SGOT normal. Electrocardiogram was normal. Chest and abdominal films were also normal. Barium enema revealed a concave defect medially and inferiorly in the cecum; there were no diverticuli. A culdocentesis revealed clear fluid, mesothelial cells and a mixed inflammatory infiltrate with moderate numbers of neutrophils; culture of this fluid was sterile. Cultures of urine and blood were also sterile and cervical cultures were negative for N. gonorrhoeae.

Hospital Course

Due to the impression that her symptoms and findings were secondary to an inflammatory process, she was treated nonoperatively with large doses of antibiotics. For two weeks her temperature ranged between 99 and 101 F. and she had several episodes of chilling. During this time she was able to eat, there was no vomiting and she passed gas and stool by rectum. Nevertheless, her fever persisted and she continued to have pain and tenderness and the suspicion of a diffuse mass in the lower abdomen persisted. In view of her failure to improve she was again operated upon on April 15, 1971.

Findings at Operation

Upon entering the peritoneal cavity, an enlarged, beefy, thickened, and indurated greater omentum was seen intimately attached to the cecum on the right and to the sigmoid colon on the left. In the pelvis it was densely adherent to the uterus, ovaries and tubes. Small bowel, including terminal ileum, was adherent to the under surface of the omentum, but, surprisingly, appeared otherwise normal. There was approximately one liter of straw-colored ascitic fluid in the abdominal cavity. There were no miliary granulomas on the seroseal and peritoneal surfaces. Tissue specimens from the omentum and peritoneal surfaces revealed marked subacute in-

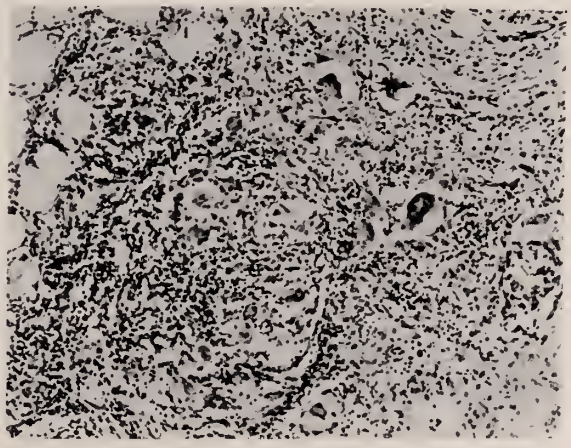

Fig. 1—H/E section (x) showing chronic inflammatory and foreign body giant cell reaction in fat.

*From the Department of Surgery, University of Minnesota, Mount Sinai Hospital, Minneapolis, Minnesota.

See editorial, page 455.

flammation with many eosinophils, numerous foreign body giant cells and some doubly refractile material. The pathologists' conclusion was that this represented a granulomatous reaction with foreign body giant cell reaction to doubly refractile material (Figures 1 and 2).

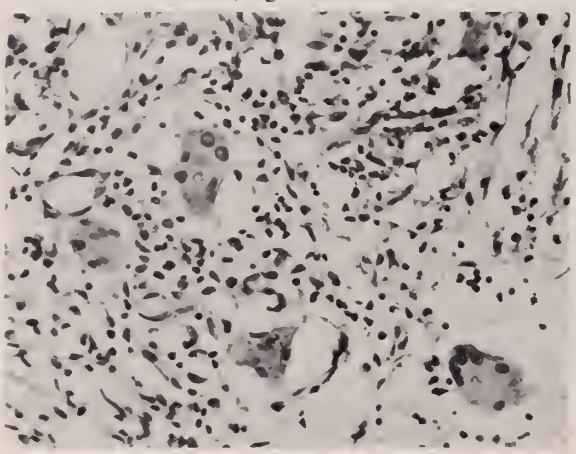

Fig. 2—H/E section (0x) showing crystalline inclusions in giant cells.

Another similar case showed thickened, indurated and inflamed greater omentum densely adherent to the peritoneum of the anterior abdominal wall and the serosa of the underlying small bowel. Approximately 1,000 cc. of straw-colored ascitic fluid were present. Frozen sections of several biopsy specimens revealed foreign body granuloma. Study of the permanent sections demonstrated doubly refractile particles in the granulomas consistent with starch powder.

Discussion

In 1916, Shatlock described a granuloma due to "silicious particles." From 1933 to 1947 many reports pointed out the potential hazards of talc when deposited in the abdominal cavity. Lee and Lehman[1] instilled one gram of cornstarch powder into the abdominal cavities of each of 10 dogs and found it to be completely absorbed without significant reaction three weeks after operation. One gram is the equivalent of that found on eight pairs of surgical gloves.

Lee[2] demonstrated that, although treated starch powder is biologically absorbable in tissue, it produces a foreign body reaction as long as it is present. The intensity, duration and reversibility of the reaction is influenced by (1) the dispersion of the powder, (2) the presence of infection or malignancy, (3) the individual hypersensitivity to cornstarch.

Sterilized cornstarch powder, Bio-Sorb, was considered superior to talc as a lubricant for surgical gloves, if precautions were taken to prevent powder contamination of open wounds and serosal surfaces, and became accepted in most surgical centers throughout the world.

Although laboratory work had demonstrated the irritative effects of starch powder, no reports of foreign body reactions in humans had been reported until 1955. Sneierson[3] reported a patient who, one month following nephrectomy for carcinoma, developed fever, chills and a fluctuant mass in the abdomen. Re-operation demonstrated foreign body granulomas due to starch powder.

McAdams[4] pointed out that "cornstarch, although absorbable, constitutes as much a foreign body as any other powder of comparable size until absorbed. The completeness of absorption and the time necessary for its accomplishment is dependent on the presence or absence of all factors conducive to inflammatory reaction." He reported five cases.

Maggs,[5] Myers,[6] Webb,[7] McNaught,[8] Hyden,[9] Taft[10] and Bates[11] have reported similar cases. The age of the patients ranged between 27 and 70 years. The time interval between initial procedure and onset of symptoms was 15 day to five and one-half weeks. Pain was steady or crampy and most often associated with tenderness not necessarily localized to the area of previous surgery. In one-half of the cases there was a low grade to moderate fever. Nausea, vomiting and obstruction were not found in all cases. The gross pathology revealed (1) copious amounts of straw-colored ascitic fluid; (2) one to three millimeter miliary granulomas covering the peritoneal and serosal surfaces; (3) multiple dense adhesions. Microscopic pathology always revealed chronic inflammation with granulomas consisting of giant cells, epithelioid cells, macrophages, lymphocytes and eosinophils. Starch granules appear red with acid-Schiff stain, and under polarized light are birefringent and show Maltese crosses. The prognosis is usually excellent. Most patients recover immediately, others have a low grade fever with pain for several weeks. One patient died of a subphrenic abscess resulting from his second exploration.

Conclusions

The relative paucity of reported cases of this

latrogenic granulomatous peritonitis is probably due to non-recogntion. Many cases of postoperative crampy pain and intra-abdominal distress may be due to this process. Rinsing one's hands in saline is inadequate for the removal of starch powder from surgical gloves. Scrupulous care in wiping away all residual powder from the gloves with a moist towel is recommended.

It's the Law

Disability Benefits Terminated for Refusal to Undergo Surgery

A 37-year-old ambulance driver sustained a ruptured spinal disc. He was unable to continue working and began receiving disability benefits. He was examined by ten physicians and orthopedic surgeons. His back pain persisted and laminectomy was recommended on numerous occasions. Despite these recommendations the patient refused to undergo surgery and after three years of treatment the Social Security Administration terminated the man's disability benefits.

According to the law anyone who willfully fails to follow prescribed treatment without justifiable cause cannot be found to be under a disability.

Aorto-Iliac Disease*

EDWARD G. ROCKWELL, JR., M.D.†

The aorto-iliac area is a common site for occlusive disease. Atherosclerotic deposits often become rather far advanced before symptoms appear, due to the large size of the vessels and the tendency for collateral to develop. Diagnosis can be made on physical examination, by decreased or absent femoral pulses. Disabling claudication is the typical operative indication.

Aortography is a useful guide to the management of these patients, not only showing the aorto-iliac area but the collateral and runoff as well, in many cases. Bypass grafting is the procedure of choice in most cases, as diffuse involvement is the usual finding. Endarterectomy is most suitable for localized involvement of the bifurcation area.

THIRTY YEARS AGO, Leriche described a syndrome which was due to atherosclerotic occlusion of the distal aorta. In his initial series, of male patients concentrated in the 50- to 60-year age group, symptoms of lower extremity fatigue, weakness, and atrophy, were associated with an inability to maintain a penile erection.[1]

The symptom of claudication is much more common than the weakness and atrophy emphasized by Leriche. While classically the pain is in the buttocks, hips, and thighs, a significant number of patients also complain of calf claudication. The calf may actually be the more common site of pain.[2-4]

Alterations in sex function are by no means a constant finding: they may be lacking in the most severe cases and often go unrelieved in spite of successful arterial surgery. In one series, a third of the patients with inability to sustain an erection were improved by surgery, but an equal percentage, normal in this respect preoperatively, complained of the loss of erection following surgery.[5]

The Patients

Most of the patients with aorto-iliac occlusive disease are males in their mid to late 50's, some years younger than patients with femoropopliteal disease. Table 1 gives some idea of average ages and male-female percentages in different series.[6-14]

A significant number of patients have high blood pressure, coronary artery disease, and cerebrovascular disease as shown in Table 2[15-18]

On physical examination there are decreased or absent femoral pulses, with bruits heard over the distal aorta, iliac, and femoral arteries, if the iliac arteries are not completely occluded. An occasional patient without femoral pulses will have popliteal and pedal pulses, due to collateral flow into the deep femoral system.

Usually the lower extremities are normal in color and warmth. There is little or no hair loss, skin atrophy, or muscle wasting. A minority of patients will present with these changes, however, and occasionally have ulceration or gangrene as well.

Criteria for Surgery

The small but real risks of arterial surgery do not justify the treatment of asymptomatic or mildlysymptomatic patients. However, claudication significant enough to interfere with the pationt's livelihood or ability to enjoy life is a reason for surgical treatment.

Rest pain, ulceration, and impending or actual gangrene represent rather urgent indications for treatment, as they suggest severe limb ischemia. Table 3 gives an idea of the indications for surgery in various series.

The Role of Aortography

Translumbar aortography was introduced by DosSantos in 1929.[19] It remains the method of choice in the angiographic evaluation of the patient with aorto-iliac occlusive disease, and can be a useful guide to operative management. It may show an unexpected aneurysm or renal artery stenosis which deserves treatment at the time of surgery. By proper timing of the second or "delayed" film, outflow can often be evaluated in the femoral segment, if the iliac arteries are open. If there is a question concerning the adequacy of the runoff, it can be studied directly by femoral arteriography.

Several surgeons have popularized translumbar aortography and have demonstrated its value and relative safety. DeBakey reported over 5,000 cases by 1966, with only two significant complications.[20]

On the other hand, aortography has been regarded by some surgeons as unnecessary. Edwards for example, believes that hypertension is the only indiciation for aortography, to determine if renal artery stenosis is present. If so, this will be corrected with the aorto-iliac disease.[21]

History of Surgical Treatment

Leriche in 1940 suggested removal of the aortic bifurcation along with lumbar sympathectomy in order to prevent propagation of thrombus and "vasoconstrictor reflexes." As grafts were not available at that time, collaterals were relied upon for lower limb survival.

The first endarterectomy was reported in 1947.[22] In 1951, Julian in the U.S. and Oudot in France described resection of the bifurcation with homograft replacement.[23-24] Degenerative changes and aneurysm formation have since made homografts outdated. As their use declined, interest developed in synthetic or prosthetic graft materials. Vinyon "N" was reported in 1952, and orlon, in 1956.[25-26] A year later, dacron and nylon were introduced, and they remain the most popular.[27-28]

In patients with severe unilateral iliac disease, whose general condition precludes a major operation, a bypass may be performed under local

anesthesia. In 1962 Vetto popularized the femoro-femoral bypass, bringing the graft subcutaneously over the pubis from one leg to the other.[29] Blaisdell introduced the axillary-femoral bypass in 1963.[30]

Subsequently Sobel has demonstrated the efficacy of CO_2 gas under pressure in separating the atherosclerotic intima and media from the outer vessel wall.[31] This method allows the removal of a solid "core" of material, including extensions into the mouths of branching vessels, and is effective over a several centimeter distance.

The More Common Methods of Treatment

With endarterectomy, or removal of the atheromatous material, the surgeon has to find the right plane of dissection, and he has to leave a smooth surface. A gradual distal taper or careful "tacking down" of remaining intima at the point where the endarterectomy is terminated is important, because a leading edge will elevate into the lumen and obstruct. If common femoral endarterectomy is necessary, it is done so as to direct blood into the deep femoral artery, which is rarely diseased beyond its proximal few centimeters.

Endarterectomy of diffuse disease—reaching into the external iliac or femoral arteries—is time consuming and tedious: however, it does offer the advantage of restoring patency without leaving a foreign material such as a graft. It is ideally suited for localized lesions of the bifurcation.

The other common method of treatment is bypass grafting; this allows correction of obstruction with the least dissection and time. Grafts are secured to the anterior walls of vessels, which tend to be less diseased than posterior walls. Proximally, the graft is placed midway between the renal arteries and the inferior mesenteric artery, where the aorta is usually of good quality. An occasional thrombectomy may be necessary at this level, but endarterectomy is usually not.

If there is localized aorto-iliac involvement, the graft is carried distally to the external iliacs. If these arteries appear significantly diseased, the graft is taken to the common femoral arteries. As in endarterectomy, emphasis is placed on revascularizing the limb through the deep femoral artery, if the superficial femoral is occluded or stenosed.

A third method of treatment is resection and graft replacement. This is necessary when an aneurysm accompanies occlusive disease, or when calcification of the aortic and iliac walls makes suturing impossible.

The Results of Surgery

It is very difficult to compare different procedures when they are used under different circumstances. While some surgeons use endarterectomy almost exclusively, and others prefer grafting, in many centers bypass grafting tends to be used in patients with more diffuse disease, because it is quicker and less technically demanding. Endarterectomy tends to be used in more localized disease of the bifurcation. Because these two procedures are used in different circumstances, for different degrees of disease, it is misleading to compare them.

Although it has not been proven, bypassed patients may have more coronary and cerebral atherosclerosis than those with localized aorto-iliac disease, thereby increasing operative mortality. Likewise, if bypassed patients have more diffuse disease, including femoral and popliteal vessels, this compromised outflow is apt to lead to failure of aorto-iliac reconstruction. Statistics suggest this relationship.

There are difficulties not only in comparing procedures, but also in arriving at an exact definition of results. Some surgeons use the life table method, which determines results at yearly intervals. On the other hand, so-called "early and late patency rates" used by others do not use exact time intervals: "early" patency referring to patency when the patient is discharged from the hospital, and "late" patency referring to whenever a follow-up study is done, including all discharged patients, at different postoperative intervals, in one group. Obviously, in evaluating results, it is important to know how percentages are determined. Often, this is not well defined. Realizing these difficulties, some different series can be examined.

TABLE 4
Aorto-Iliac Disease
Surgical Treatment
234 Cases

Bypass Graft	(119)	50%
Endarterectomy	(92)	40%
Combination	(23)	10%
Overall Early Patency		85%
Graft	(80%)	
Endarterectomy	(92%)	
Combined	(86%)	
Overall Late Patency		77%
Graft	(66%)	
Endarterectomy	(79%)	

In Table 4, the University of Rochester experience (Minken et al.), shows superior early and late patency rates for endarterectomized patients. However, endarterectomy tends to be used in more localized (and, therefore, more favorable) disease: in particular 48 of 90 endarterectomized patients had unilateral iliac disease.

Table 5 reviews the Baylor University experience. Most of the patients were bypass grafted although graft and endarterectomy results are grouped.[32] Late patency was 94% in a more recent survey from Baylor, with the number of patients then exceeding 3,000.[33]

TABLE 5
Aorto-Iliac Disease
2,029 Patients
1,306 Cases—Bypass Graft
179 Cases—Endarterectomy
544 Cases—Resection with Graft
Late Patency in 1,955 Cases (95%)

In Table 6, an English series (Dickenson, McNeil, and Morrison) superior patency rate for bypass grafted patients contrasts with results in other series.

Table 7 shows the Barnes Hospital results.[34] While endarterectomy had early superiority, this form of repair continued to occlude, so that at five years, patency rates were essentially equal.

Attempting to reconcile results from different authors, a compilation of late patency rates by author and year, in some larger series, is shown in Table 8.

Complications of Surgery

Thrombosis in the immediate postoperative period is the most frequent and significant complication of surgery, whether bypass grafting or endarterectomy is used. The incidence of this problem in a few different series is shown in Table 9.

Various factors have been incriminated in the etiology of early thrombosis. In the analysis of nine cases shown in Table 10 (Buckberg et al.), obviously more than one factor was present in several cases. It can be seen that poor runoff, or distal disease, was the main one.

Mortality in a few series is shown in Table 11. Rates are definitely higher for the grafted patients, due to their being greater operative risks, with more diffuse disease.

Influence of Femoro-Popliteal Disease

In four different series (Table 12) the authors divided the cases into groups, depending on whether or not femoro-popliteal disease was also present. Most of these represented superficial femoral occlusion. It can be seen that significant femoro-popliteal disease will affect the results of aorto-iliac reconstruction. The majority of patients will still be relieved of their symptoms if the limb is revascularized through the deep femoral system, carrying the graft or endarterectomy to the common femoral artery at the deep femoral takeoff. Only a small percentage of patients require a subsequent femoro-popliteal bypass if this is done.

Nuclear Medicine

Current Concepts

MERLE K. LOKEN, M.D., Ph.D.*, J. THOMAS PAYNE, Ph.D. AND
RICHARD A. PONTO, B.A.

THE PRACTICE OF Nuclear Medicine relates to the development, evaluation and propagation of various uses of radioactive materials in the diagnosis and treatment of disease. To this end, consideration is given to the availability of radioactive materials, to the availability and performance of devices for measurement of radioactivity, to a clinical evaluation of procedures performed and to the radiation hazards to patients and clinic personnel.

The initial use of radioactive materials in medicine followed shortly after the discovery of radioactivity by Becquerel in 1896. Following World War II, there has been a steady increase in the availability of reactor-produced radioactive materials so that today there are several hundred radionuclide preparations available for use in medicine and medical research. There is little doubt that the number of these radiopharmaceuticals will be increased substantially in the future with emphasis on those which have either a very short† physical or biological half-life or both and will permit the administration of quantities of radioactivity to patients with only a few millirads[1] of radiation exposures.

Radioisotopes

The rapid growth and availability of radioisotopes has been paralleled by similar advances in nuclear instrumentation. The sensitivity of nuclear instruments, together with physical properties of the radioisotope used (half-life, types of emissions) governs the radiation exposure to patients and personnel.

Instruments

A wide variety of instruments are available for use in Nuclear Medicine, all of which have some means of detecting and recording radioactivity, and, all of which employ a scintillation crystal detector coupled with a spectrometer for analysis of gamma ray energies of the radionuclides being used. Beyond this, instruments differ depending upon their particular application: for assay of radioactivity a scaler is generally used; if information is desired on the rate of uptake and clearance of a radioisotope from an organ, such as in studying the function of a renal transplant, then a rate meter and strip chart recorder are usually employed; images (scintiphotograms) of body organs containing radioactivity are obtained using a rectilinear scanner or scintillation camera. The camera is an instrument of relatively recent design and is used for studies in which dynamic function data are desired in addition to scintiphotograms. There appears to be little doubt that future developments in camera systems will provide significant improvement in resolution of scintiphotograms so that they will begin to approach the image quality currently available in conventional radiographic procedures.

Computer

With the aid of computer analysis, currently an integral part of many of the diagnostic procedures in Nuclear Medicine practice, quantitative information can be obtained relative to regional function and blood flow in a variety of body organs. A summary of these and other Nuclear Medicine procedures are listed in five categories in the Table.

Nuclear Medicine must employ the special talents of physicians in nearly all clinical specialties as well as researchers in the basic medical sciences, in order to carry out an effective and expanding program.

Case Reports

Lung Study

An example of a radionuclide lung examination is shown in the following case study on a 61-year-old patient

*Director, Division of Nuclear Medicine, University Hospitals, Minneapolis.

†Seconds to minutes.

with progressive dyspnea. Selected scintiphotograms from the radionuclide studies show several areas of decreased perfusion in the lung (Figure 1). This pattern might also be seen in studies of patients with multiple pulmonary emboli. However, the scintiphoto obtained following a single breath of 133-Xenon (V_1) shows that these same areas are also poorly ventilated, indicating the presence of obstructive lung disease. This impairment in ventilation is also very well demonstrated in the washout portion of the 133-Xenon study which shows multiple foci of residual radioactive Xenon resulting from poor ventilation in these areas. The data from the study on this patient were processed by a computer and some of the analyses are shown in Figure 2. The computer output provides quantitative determinations of regional ventilation-perfusion (V/Q) ratios and 133-Xenon clearance times (T½ seconds). The normal (V/Q) ratio is about one.[2] In this study considerable variation in the (V/Q) ratio is demonstrated, particularly in regions also showing prolonged clearance half-times. These data indicate the severity of impairment of pulmonary function in patients with lung disease (Figures 3, 4, 5, 6).

Renal Function

For this examination 131-Iodohippurate (200 uCi) was administered intravenously to evaluate the renal function[8] in a patient with severe scoliosis. Selected scintiphotograms are shown in Figure 3.

At three minutes after intravenous injection, an accumulation of radioactivity is seen in both kidneys. Later scintiphotos show gradual excretion from the kidneys into the bladder. The data from this study were processed by a computer to provide quantitative information relating to the flow of radioactive material through the kidneys and into the bladder. The rapid accumulation and prompt excretion by both kidneys in this examination is an example of normal renal function despite severe scoliosis.

Cardiac Angiography:

A radionuclide angiogram[9,10] is shown in Figure 4. For this examination, a dose of 15 millicuries of 99mTc-pertechnetate was injected intravenously as a bolus. Serial scintiphotograms of the anterior projection of the heart taken at two-second intervals show the flow of the radioactive material through the heart and lungs. In this study, an abnormal concentration of radioactivity

in the region of the left ventricle represents an aneurysm.

Cerebral Arteriovenous Malformation

This 18-year-old male was referred for further evaluation of a right cerebral arteriovenous malformation which had been partially resected.[11] Neurologic examination indicated a mild left hemiparesis and a left homonomous hemianopsia. A lateral scintiphotogram obtained at 30 seconds after an intravenous injection of 10 millicuries of Tc^{99m} demonstrated a large abnormal focus of activity in the right posterior temporal parietal area extending posteriorly and superiorly toward the superior sagittal sinus (Figure 5). This defect persisted in a later scintiphotogram taken at 45 minutes post injection. Subsequent to this study a right brachial angiogram confirmed the presence of an AV malformation supplied by an enlarged right posterior cerebral artery and draining via numerous large cortical veins into the superior sagittal sinus. Surgery was performed to remove the AV malformation.

A postoperative rapid flow and static scintiphotographic study was within normal limits (Figure 6). Graphs of radioactivity passing through the region of the malformaiton were obtained via computer analysis of the preoperative and postoperative scintiphotographic studies. The postoperative scintiphotographic study indicates a normal pattern of flow in both the areas of the previous arteriovenous malformation and sagittal sinus. The patient experienced significant clinical improvement after surgery.

Case 2

Jaundice

A 50-year-old white female was admitted for evaluation of prolonged jaundice, with a tender liver and recurrent febrile episodes. Routing X-ray studies were negative. Liver scintiphotograms using 2 millicuries of Tc^{99m} sulfurcolloid demonstrated a large (filling) defect in the posterior superior aspect of the right lobe thought to be compatible with an abscess (Figure 7). At surgery

Fig. 7—Four views of a liver study using 2 mCi Tc^{99m} sulfurcolloid. Note the large defect in the superior portion of the right lobe.

75 ml of pus were drained from an encapsulated abscess, after which the patient made an uneventful recovery.

Comments and Conclusions

The future of Nuclear Medicine shows much promise. Continued advancements in the quality of radiopharmaceuticals and instrumentation including computer processing of data will increase the diagnostic information obtained from Nuclear Medicine studies. It should be emphasized that computer processing of data should not be considered a limiting factor to the practice of Nuclear Medicine. Although several of the case studies presented in this article involve the use of a computer, the appropriate clinical interpretations could have been made adequately utilizing the scintiphotographic images alone.

Delayed Anemia

In Erythroblastosis Fetalis

CALVIN STRAND, M.D.* and HERBERT F. POLESKY, M.D.†

In recent years the literature on hemolytic disease of the newborn has emphasized amniotic fliud examination, intrauterine transfusion, phototherapy and prophylaxis with Rh Immune Globulin. These advances in the diagnosis, treatment, and prevention of erythroblastosis fetalis have diverted attention from, but not altered the importance of prenatal blood typing, antibody screening and post delivery hemoglobin determinations as indicators of possible hemolysis.

We present here nine cases of erythroblastosis fetalis. The first four (Table 1) had appropriate prenatal studies which led to early diagnosis. These cases are of interest because the expected hemolysis and postnatal anemia were delayed in onset. They illustrate the importance of careful postnatal followup in infants only mildly or moderately affected. In the second group of five cases (Table 2) correct diagnosis was delayed because of omission or errors in blood typing and antibody screening or failure to study the infant.

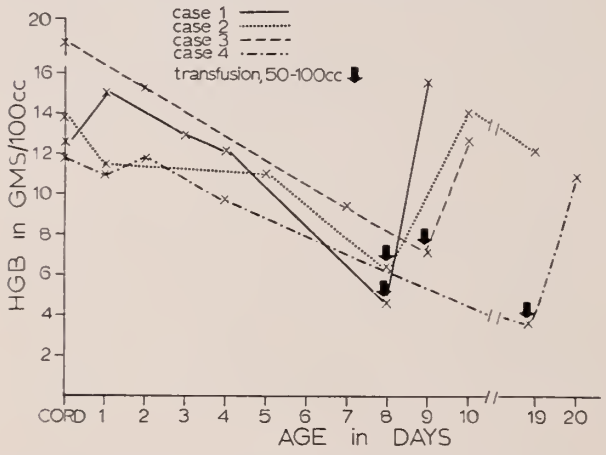
See editorial, page 457.



Discussion

Severe erythroblastosis fetalis is characterized by development of anemia due to autohemolysis of erythrocytes coated with maternal antibodies. Prenatal studies including antibody titers and amniocentesis were used to predict the condition of the fetus and its need for therapy in Cases 1-4 (Table 1). Three of the four women (Cases 1, 2, 4) had previously delivered affected infants. However, at birth the infants of the present pregnancy did not show evidence of severe hemolytic disease. Anemia requiring transfusion did not develop until eight and nine days (Figure). The need for transfusion in Cases 1-3 was determined by development of pallor, lethargy, failure to nurse and frequent measurement of their hemoglobins. The two-week interval between discharge

TABLE 1
Cases with Appropriate Prenatal Testing in which Onset of Anemia was Delayed

Case	Age	Gravidity	Past history	Antiglobulin Antibody titer (Rh_o(D)	Amniocentesis	Comment
1	28	3	One erythroblastotic infant	256	23 & 28 weeks Lower Zone II 33 weeks Zone I	Hemoglobin of infant dropped 8 grams in 4 days
2	43	8	Two previously affected infants	128	26 & 28 weeks Zone II 35 weeks Zone I	Mildly affected premature infant with gradual drop in hemoglobin
3	30	3		1	20, 22 & 30 weeks Zone I	Titers not followed
4	38	6	Two previously affected infants	512	35 weeks Zone I	Hemoglobin of infant not closely followed

and followup hemoglobin in Case 4 is too long. Though this patient had good prenatal care she could be added to the second group of cases where errors in management affected the diagnosis. Delayed anemia may also occur in infants that have been treated for erythroblastosis by exchange or simple transfusion. All moderately or severely affected infants should be followed with weekly hemoglobins until they are stable. Parents should be instructed to report to the physician if difficulty in nursing or lethargy develops.

Figure—Serial hemoglobin values in four infants with delayed onset of anemia. Note prompt response to transfusion of 50-100 cc of packed red cells.

Authors disagree as to the cause of delayed onset of anemia in erythroblastosis fetalis. Some have published case reports showing evidence of bone marrow hypoplasia.[1,2] However, Dillon and Krivit,[3] in a study of serial bone marrow specimens from fourteen affected infants, could find no convincing cases of hypoplasia and, on the contrary, noted that marrows showed erythroid hyperplasia proportional to the severity of anemia. Support for their observations was obtained in Case 7 where marked normoblastic hyperplasia in the marrow and extramedullary hematopoiesis were present at autopsy of an eleven day old infant that died shortly after transfusion.

Importance of Prenatal Testing

The second group of cases (Table 2) re-emphasizes the need for all pregnant women, whether Rh positive or Rh negative, to have ABO and Rh typing, and screening for irregular antibodies in each pregnancy. Recognition of the etiology of the anemia in the infants in Cases 5-9 was delayed because of errors of omission and commission. The most common error was failure to do maternal antibody screening and identification (Cases 5-9) which was compounded by mistyping of the mother's blood as Rh positive (Cases 5-8). Had antibody screening been done in these pa-

TABLE 2
Cases in which Diagnosis was Delayed because of Omission or Technically Incorrect Performance of Routine Tests.

Case #	Mother: Past History	Mother: 1/antibody titler (Rh_o)	Infant: Lowest Hgb gm/100 cc	Infant: Age (days) transfused	Comment
5	4 unaffected pregnancies	64	11.9	4	Mistyped as RH positive No prenatal antibody screening
6	Transfusion of Rh positive blood	1024	5.5	12	Mother typed Rh positive in previous pregnancy. No typing or antibody screening during pregnancy
7	2 unaffected pregnancies	1024	2.4	11	Typed as Rh positive in previous pregnancy. No studies this pregnancy.
8	7 unaffected pregnancies	64	7.4	30	Incorrectly typed. No prenatal antibody screening.
9	Transfusions	32*	3.6	16	No cord blood testing or hemoglobins on infant from Rh positive mother known to have atypical antibodies

*Anti-rh "(E).

tients[5-8] it would have raised a question about the results of typing since anti-Rh_o(D) does not usually occur in Rh_o(D) positive individuals. Errors in blood typing, particularly when done by untrained personnel occur with some frequency. In a large metropolitan hospital 3.2 percent of 280 obstetrical admissions who had been previously typed in the doctor's office were found to be in error.[4] In a California study,[5] laboratory factors were contributory in 35 percent of 328 deaths due to erythroblastosis.

The importance of testing in each pregnancy is illustrated by Cases 5 and 8 where three and six apparently normal pregnancies preceded the child with erythroblastosis.

Case 9 points out the importance of typing and antibody screening in routine prenatal studies on Rh positive women. This gravida 3 para 2 Caucasian had a placenta previa and required Caesarean section. Though it was known that she was sensitized to Kell, Fy(a) and rh"(E) no studies were obtained on the infant who at sixteen days of age was admitted to another hospital with "unexplained" anemia. In a study of over 27,000 Rh positive pregnant women, 1.3 percent had atypical antibodies.[6] In addition to delivering unexpected erythroblastotic infants, these sensitized women can present as transfusion problems that may be difficult to solve in an emergent situation.

Acknowledgment

The assistance of Drs. Charles Chedister, Norman Horns, Edward Segal and the several physicians who treated the mothers and infants is gratefully acknowledged.

Medullary Syndrome

This syndrome comprises one of the clinical variations produced by thrombosis of the anterior spinal artery that supplies the medulla oblongata. The thrombosis occurs near the site where the vessel has its origin from the vertebral artery. Spiller in 1908 first postulated a syndrome that might result from occlusion of the uppermost portion of the anterior spinal artery. It occurs rarely; Davison reported a total of four cases in 700 cerebrovascular accidents that came to autopsy.

The clinical features consist of contralateral pyramidal tract signs of the trunk and upper and lower extremities, contralateral loss of discriminative sensibility in the arms and legs, and occasionally ipsilateral paralysis and atrophy of the tongue. The syndrome may be unilateral or bilateral. If bilateral it is characterized by a spastic tetraplegia with loss of sensation below the lesion. Sphincter and bladder incontinence are usually present. In anomalies where only one anterior spinal artery exists, both pyramids and medial lemnisci may be involved.

High Velocity Missiles

The Importance in Arterial Wounds and Fractures

LT. COL. RAYMOND G. ARMSTRONG, USAF, MC*,
HENRY J. SCHMITT, JR., M.D.†, AND LEWIS T. PATTERSON, M.D.‡

THE AMPUTATION rate is significantly higher in arterial wounds associated with fracture compared with arterial wounds without fracture.[1] However, the reason for the increased amputation rate has not been properly defined. The present report on Viet Nam casualties confirms previous observations and shows that the increased amputation rate in cases with associated fracture is a direct consequence of wounding by high velocity weapons rather than due merely to the presence of the associated fracture alone.

Study Group

The 248 patients in the study group had sustained arterial injuries from hostile fire and had received initial wound care in Viet Nam. All were admitted to the USAF Hospital, Clark AFB, Philippines, between 1 July 1965 and 31 December 1966. Of the 269 arterial injuries of the extremities, 171 (63.6%) involved major arteries and 98 (36.4%) involved named minor vessels. Fifty-eight of the 171 major arterial injuries and 71 of the minor injuries had associated fractures (Table 1). The distribution of wounding and incidence of associated fracture for the entire series is given in Table 2.

As expected, the incidence of associated fracture was greater the more distal the site of injury. Twenty-seven percent of these patients also had associated thoracic and/or abdominal wounds.

Wounding Agent

The cause of missile injury in Viet Nam has changed significantly compared to World War II and the Korean War.[2] In the latter conflicts, at least 75 percent of the battle casualties resulted from fragmentation injury and only 25 percent from gunshot wounds. However, in Viet Nam approximately 50 percent of all wounds resulted from high velocity small arms fire.[3] This difference is probably due to the increased number of search and destroy missions in which the individ-

ual is more exposed to sniper fire.

The importance of the high velocity agent as a cause of associated fracture in shown in Table 3. The overall incidence of associated fracture in major artery injury was nearly twice when the wounding agent was a bullet compared with a fragment ($p < 0.001$) (Table 3). However, when the data were regrouped with respect to the extremity involved, certain notable differences were found (Table 4). In the case of the upper extremity, wounds with associated fracture were significantly more often produced by bullets than by fragments ($p < 0.01$). However, in the lower extremity, the difference in incidence between bullet and fragment as the wounding agent was not significant whether a fracture was caused or not. This difference between the extremities is explained by the fact that approximately 50 percent of the fragmentation injuries of the lower extremity resulted from stepping directly onto land mines. In such cases, this proximity to the wounding agent caused a blast effect, or allowed several discharged fragments to strike with high initial velocities and produce wounds similar in effect to those caused by high velocity bullets.

Treatment

Ligation

In minor arterial injuries, the vessel was ligated 83.7 percent of the time, whether a fracture was present or not.

Anastomosis—Repair

Of the 16 minor vessels not ligated, 11 were of the tibial-peroneal group with seven associated fractures, and five were of the radial-ulnar group with four associated fractures. For these 16 vessels, a direct anastomosis was carried out nine times and a lateral repair seven times, but there was no correlation between the type of treatment and the presence of a fracture.

As far as the *major arterial injuries* are concerned, an associated fracture had no influence on the initial type of treatment. Vein graft, vein patch, anastomosis, lateral repair, prosthesis and ligation were used with about the same frequency in major arterial injuries with fracture as in those without fracture. Moreover, where the initial treatment was some form of repair (initial ligations excluded, the type of treatment selected was not influenced by the type of wounding agent, whether a fracture was present or not (Table 5).

Immobilization

All fractures associated with minor arterial injuries were immobilized by plaster casts or splints except for one case of combined anterior and posterior tibial artery injury in which the tibia was immobilized with an intramedullary rod. For fractures associated with major arterial injuries, 74.1 percent were immobilized in plaster, whereas 25.9 percent were treated with internal fixation. The incidence of internal fixation per major vessel is shown in Table 6 along with the types of internal fixation used. Internal fixation was used in these patients because at the time of arterial repair the unstable fracture was seen to angulate sufficiently to compromise arterial flow. One of these patients who had a superficial femoral artery injury underwent internal fixation at Clark Air Base at the time

of re-operation for thrombosis of a vein graft because angulation and occlusion occurred after replacement of the graft.

Amputation

Amputation may be taken as the endpoint of failure in the treatment of arterial injuries of the extremity. Ischemic gangrene is the leading cause of amputation after arterial repair is attempted. However, to a lesser degree limbs may be sacrificed because of gas gangrene, unrelenting infection accompanying extensive associated soft tissue or osseous injury, and because of sequelae of major peripheral nerve injury.

Results

As a consequence of the 269 major and minor arterial injuries of the extremity in this series, there were 73 amputations (27.7%). Seventy amputations (95.9%) resulted from ischemic gangrene, and three from gas gangrene. In the latter three patients, gas gangrene developed after successful repairs of superficial femoral and popliteal artery injuries (neither associated with a fracture), and in one patient after ligation of anterior and posterior tibial artery injuries with an associated fracture.

When initial ligations and gas gangrene were excluded from consideration, the amputation rate for major arterial injuries of the extremity with fracture was twice as high as when there was no associated fracture ($p < 0.01$) (Table 7). With the minor arterial injury group, however, the difference in amputation between those patients with a fracture and those without proved not to be significant as might be assumed at first glance ($p < 0.30$). The lack of significance between these two latter groups probably relates to the fact that the vast majority (83.7%) of all named minor arterial injuries were treated by ligation and that in the majority of injured limbs two or three of the minor vessels were ligated.

The findings of DeBakey and Simeone in an analysis of World War II casualties were similar to those in the present series (Table 8). The relative increase in the amputation rate in both series for major arterial injuries with an associated fracture does not seem to be a reflection of the type of initial treatment. The 154 major arterial injuries of the present series were repaired initially, while the 277 injuries analyzed in the World War II series were selected for study from 1,774 arterial wounds, 92.4 percent of which were ligated initially.

No significant difference in the amputation rate was found when internal fixation was compared with external immobilization. However, because of the small number of cases of internal fixation in this series, no significant recommendations can be made for its use. Internal fixation may certainly be of benefit in selected cases when stability and angulation of the fracture threaten to compromise the vascular repair.

An important factor to be considered in the influence of associated fracture on the amputation

TABLE 7

rate was the type of wounding agent involved. In a group of 26 amputations from major arterial injuries of the extremity with fracture, the most frequently responsible wounding agent was a high velocity bullet (50%), whereas in a corresponding group without fracture it was a fragment (77%) ($p < 0.05$) (Table 9).

TABLE 9

*Excluding amputations due to gas gangrene and where the initial treatment of the arterial injury was a ligation.

Conclusions

When vascular injuries of the extremity are associated with fractures, the amputation rate can be expected to be significantly higher than in the absence of fractures. However, the significant correlation is not between the presence of a fracture, *per se,* and amputation, but rather between amputation and a high velocity wounding agent. Fracture is merely a consequence of the high velocity wound in addition to more soft tissue damage and disruption of the collateral circulation; collectively, these increase the chance for ischemic gangrene and the need for amputation.

The type of treatment used to manage major arterial injuries does not seem to have any influence on the relative outcome in wounds associated with fracture compared to those without fracture. The amputation rate is significantly higher with associated fracture than without in both this series in which 90 percent of major arterial injuries were treated initially by some type of vascular repair and the World War II series of DeBakey and Simeone[1] in which 92 percent were treated initially by ligation. However, the net results with and without fracture are relatively better in Viet Nam than in World War II because of the current use of arterial repair rather than ligation.

Concomitant Myelomonocytic Leukemia and Multiple Myeloma

LUIGI TADDEINI, M.D., F.A.C.P.* and WAYNE SCHRADER, M.D.*

A NEW SYNDROME of plasma cell dyscrasia culminating in acute leukemia has been recently recognized.[1,2,3,4,5,6,7] In all reported cases of this syndrome, the appearance of myelomatosis preceded the development of acute leukemia, and in all instances the patients had received treatment with cytotoxic agents prior to the terminal leukemic crisis, suggesting the possibility that prolonged chemotherapeutic suppression of multiple myeloma may act as a leukemogenic factor.

We have observed a patient in whom acute myelomonocytic leukemia and multiple myeloma were simultaneously present at the time of diagnosis. The association of these two conditions, in a patient who had neither received prior therapy, with alkylating agents nor radiation treatment has not to our knowledge, been previously reported. The description, course, and postmortem findings of this unique case forms the subject of this paper.

Case Report

A 73-year-old caucasian male was referred to St. Paul-Ramsey Hospital in December 1968, because of anemia and hepatosplenomegaly. He had received six units of blood prior to admission. The patient bruised easily and had leg pain for 10-12 months. There was no history of chronic infection, toxic or radiation exposure. Physical examination revealed large ecchymotic areas on both arms, and generalized petechiae over the anterior surfaces of the lower extremities. The liver was felt three cms below the right costal margin, and the spleen was palpable 6 cms below the left costal margin. Several lymph nodes 2-3 cms in diameter were palpable in the left axilla, and in both inguinal regions.

The hemoglobin was 10.8 gms%, and the white count was 9,000 with 38% PMNS, 24% lymphocytes, 11% monocytoid cells, 3% basophils, 8% myelocytes, 1% plasma cells, and 15% blasts. There were 5 normoblasts/100 WBC. Platelet count was 16,000 and the reticulocyte count was 2.8%. The creatinine was 1.3 mg and BUN 38. Bone marrow examination revealed a hypercellular specimen with 50% blasts (Figure 1). There was a decrease in number of megakaryocytes as well as 8.8% mature and immature plasma cells. The blast cells, particularly in the peripheral blood, had a monocytoid appearance. They stained Sudan black positive and an occasional Auer rod could be found. Erythropoiesis was decreased with megaloblastoid features.

Because of the increased number of plasma cells in the marrow, a serum electrophoresis was obtained. This revealed a monoclonal peak of 1.7 gm% in the gamma region. Bence-Jones protein was negative in the urine and bone survey demonstrated areas of increased radiodensity in the medullary canal of the right tibia.

The patient was treated with a combination of 6 mercaptopurine, prednisone, vincristine and methotrexate as well as platelet and blood transfusions. A serum electrophoresis repeated two weeks after initiation of treatment revealed an even greater sharp spike of 2.9 gm % in the gamma region (Figure 2) and immunoelectrophoresis characterized the spike as an IgG immunoglobulin lambda chain type.

Bone marrow aspiration repeated after eight weeks of chemotherapy revealed a hypercellular marrow with 4.3% blasts, and 15% abnormal plasma cells (Figure 3). Marrow biopsy showed an overwhelming predominence of atypical plasma cells diffusely distributed throughout

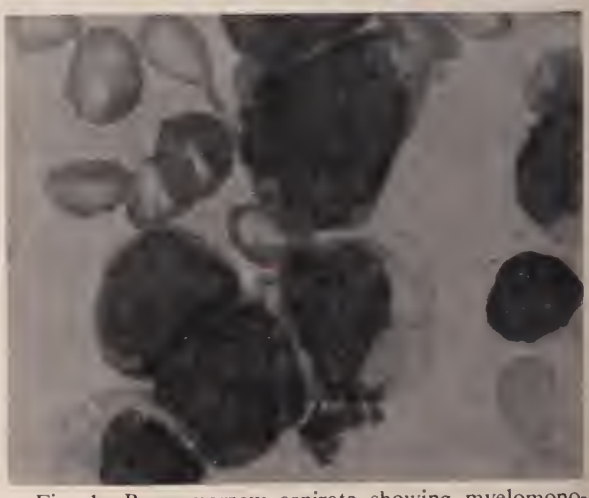

Fig. 1—Bone marrow aspirate showing myelomonoblasts at the time of initial diagnosis. (Wright's stain—Original magnification x 1000).

the bone marrow tissue stroma (Figure 4). Bence-Jones protein was positive in the urine at this time, and the diagnosis of multiple myeloma as well as acute myelomonocytic leukemia in partial remission was made.

The patient was started on small doses of cyclophosphamide but remained severely thrombocytopenic and anemic, requiring frequent transfusions. He died six weeks later of a cerebral hemorrhage.

Postmortem examination revealed an enlarged liver and a moderately enlarged spleen (250 gms) with evidence of extramedullary erythropoiesis. The marrow was hypercellular and was almost entirely replaced by myeloma cells with marked reduction in number of myeloid and erythroid elements. No evidence of a malignant myeloid process could be found.

Discussion

Osserman et al.[1,8] described a patient with a history of chronic urinary tract infection for many years who developed multiple myeloma at the age of 41. He was treated with radiation, urethane and melphalan, and died four years later shortly after developing evidence of acute myelomonocytic leukemia.

Nordenson[9] describe two cases of acute myeloblastic leukemia, and five cases of acute lymphoblastic leukemia, in a review of 310 cases of myelomatosis, but no details concerning the leukemias were given. Edwards and Zawadzki[2] reported the case of a patient who died of acute leukemia ten years after the diagnosis of myelomatosis for which he had received treatment with radiation, urethane and cyclophosphamide.

More recently Kyle et al.[3] discussed in detail the occurrence of rapidly progressive acute myelomonocytic leukemia in three patients with myeloma, and in one with primary amyloidosis who had received prolonged courses of melphalan therapy ranging from 30 to 57 months. Because of the remote likelihood of chance association of these two rare hematological disorders, the authors emphasized the possible role of melphalan therapy in the development of acute leukemias in their patients.

Four additional patients with myelomatosis in whom acute stem-cell leukemia developed were described by Andersen and Videbaeck in Copenhagen.[4] Like Kyle's cases all four patients had been given chemotherapy treatment with melphalan for long periods; two of them had had cyclophosphamide as well, and two had had radiotherapy. The Copenhagen workers reasonably pointed out that the long continued use of an alkylating agent might be capable of evoking

acute leukemia in man. They also postulated, however, that the terminal acute leukemia might be the result of a natural evolution of multiple myeloma and that a close relationship might exist between myeloma cells and blast forms.

Holland, in an editorial review of this subject[6] stated that in the past three and one half years, he and his colleagues have observed five cases of myelomatosis culminating in acute leukemia after prolonged chemotherapy.

Farhangi and Osserman[5] have lately observed two more cases of acute myelomonocytic leukemia as a late complication in plasma cell dyscrasia. The authors postulated that the development of leukemia in multiple myeloma is possibly related to a relationship between monocyte and plasma cells, the former representing a more primitive defense mechanism than the plasma cell-immunoglobulin system in the course of phylogenetic evolution.

Paraproteins have been reported in acute leukemia without myeloma.[10,11,12,13] Recently Thijs et al.[14] described a case of blast cell leukemia with IgA paraproteinemia and Bence-Jones protein Kappa type. Immunofluorescence investigations provided evidence that some blast cells contained K type light chains indicating that at least part of the blast cells could be considered immunologically active.

In our patient the appearance of acute leukemia could not be attributed to previous chemotherapy or radiation exposure. Even such rare conditions as myelomatosis and acute leukemia may be fortuitous, but on the basis of previous reports suggesting a relationship between blast cells, and myeloma cells this seems an unlikely possibility. The simultaneous presence of blast cells and myeloma cells in the same individual supports, in our opinion, the view of the existence of an evolutionary connection between these two types of cells, but unfortunately no immunofluorescence studies[14] were done to verify this relationship.

It is of interest that intensive chemotherapy produce in our patient remission of acute leukemia but an apparent increase of myeloma cells in the marrow and an increase of paraproteins in the serum suggest the possibility of a nearly complete transformation of one type of malignant proliferation into the other. The postmortem findings confirmed the presence of an overwhelming proliferation of myeloma cells but no evidence of acute leukemia.

As pointed out in an editorial review of this subject[7] the possible relationships of acute leukemia, myelomatosis and various chemotherapeutic agents can only be confirmed by careful, continuous reporting until adequate statistics are obtained. The case reported in this paper indicates, that the two hematological conditions can occur independently from the effect of cytotoxic drugs, and perhaps suggests that they may be part of the spectrum of the same disease.

Case Report

Traumatic Luxation of the Testis

JOSEPH N. AQUILINA, M.D.*

THE NORMALLY descended testis can be dislocated along fascial planes or through normal anatomic apertures by sheer traumatic force. Ockuly in 1946, while describing a case of bilaterally luxated testis, established the principle that only a previously normally descended testis can be classified as a traumatically luxated one.[16] The testis itself is usually unharmed but it may be separated from its epididymis through a partial tear or may perhaps have torn fascial coverings.[13]

Historical Review

The first cases of testicular dislocation were published by Claubry in 1818 in Paris, and later by Liddon in London in 1858.[4-11] In 1890, Howlet published a case of a normally descended testis dislocated into the fascial coverings of the penis.[8] About 50 cases have so far been published in the literature and only 10 of these have been bilateral.[14-16] Guiteras published a case in which the testis was found on the side of the penile shaft; and Kaursch, another in which the testis was luxated to the undersurface of the penis.[6-10] The cases reported by Howlet and Guiteras had both been reported to have suffered tearing of the epididymis from the testis during the accident.[6-8] Schuerer-Waldheim excised an internally dislocated testis after two years because it had developed a seminoma.[17] Jurinka and Bancale each reported a case of traumatic luxation of a testis into the acetabulum.[2-9] Sethi et al. reported on a testis dislocated beneath the prepuce for a period of two years, during which time the patient had married and sired a daughter.[18] Only two cases of testis luxation into the abdominal cavity have been reported.[17-18]

Clinical Features

These injuries usually occur as a result of a wheel passing over the genital region or from a straddle injury. The most common associated injuries are pelvic fractures, femoral fractures, dislocation of the hip, contusion of the inguinal ligament and skin contusion.[13]

The classification of Alyea (1929) is still accepted today.[1] Morgan suggested that this classification should not include those testes which are luxated as a result of a scrotal tear.[13] This classification of testes luxated superficially includes those luxated to the crural, penile, perineal, superficial inguinal and pubic regions; those classified as luxated internally include those in the inguinal or femoral canal, as well as abdominal and acetabular luxations. The most common superficial luxations are found in the superficial inguinal and pubic regions.

Case Report

A 47-year-old white male was pulling a car from a snow bank with a wrecker truck. While doing this he noted that the cable did not wind itself properly on the winch. He therefore tried to disentangle this by unwinding the cable and then rewinding it. During the process of winding the cable he accidentally stepped inside a couple of loops of cable and was caught at the upper thighs and left dangling from the winch. Luckily this stalled and shut off the motor. After his rescue by a farmer, the patient was admitted to the hospital. His injuries included a fractured left femur, fractured distal right ulna, partial amputation of the third and fifth fingers, as well as pressure necrosis and skin contusions circumferentially around his thighs. He was also noted to have an abdominal mass about three inches above the right inguinal ligament. When I saw him, the third day after the accident, the scrotum on the right was well developed and empty (positive Brockman sign); that on the left had a normal testis. The right testis was palpable just beneath the subcutaneous tissues where the mass had been described. There was a generalized hematoma of the scrotum. No panile injuries were present. Under gentle massage, the testis was replaced into the scrotum with some discomfort to the patients.

Comments

The first manual reduction of a dislocated testis was performed by Connor in 1861,[5] the first operative reduction by Nicholas in 1899.[15] In 1929 Alyea reviewed 20 cases in the literature and stated that 11 patients underwent open reduction and three closed reduction; six were not treated.[1]

*Mankato Clinic, Mankato, Minnesota. Present location: 3406 Davenport, Saginaw, Michigan.

Herbst and Polkey reviewed 93 reported cases, only 39 of which were regarded as true traumatic dislocated testes; the others were either cases of rupture of the testis, effort luxation or dislocation by a truss of a congenitally ectopic testis.[7]

The same authors performed an experimental study of testicular luxation and concluded that while luxation can occur with relative ease, reduction was often difficult.[7] They also showed that fascial coverings of testes were often damaged during the process of traumatic luxation. This explains at least two causes for difficult testicular reduction: hematoma and edema, and organizing scar tissue. Those who have operated for cryptorchism know that often there are abnormal attachments of Scarpa's fascia to the pubic bone. This was originally described by Browne in 1938.[3] Morgan suggests that when this fold remains after foetal descent of the testis, it may became a factor in preventing reposition.[13] McGregor also described the so-called third inguinal ring which may be a factor in prevention of reduction as well as luxation.[12] It is because of this fascial ring or funnel at the neck of the scrotum that traumatic force has to be of sufficient strength and in the proper direction to force the testis through the ring. In manual reduction of a luxated testis, sufficient pressure has to be exerted to force the testis through this ring. Edema and hematoma may cause a hang-up at this anatomic location. This is where waiting a few days usually pays off. In this case reduction took place without much difficulty on the third day.

DOW PHARMACEUTICALS

Femininity & Vaginitis

Many women still believe that a douche is a cure-all for vaginal secretions and malodor. Mother to daughter and the myth is perpetuated.

Other cosmetic products are not much better. Though they may be effective in some minor infections, they cannot touch the real medical problem, which very often is trichomonal vaginitis.

Medicine's most effective cure for trichomonal vaginitis is Flagyl® (metronidazole). It is also pleasantly feminine because it provides the simplicity of oral medication . . . frees women from the unpleasant mess and bother of douches.

When the problem is trichomonal vaginitis . . . remember Flagyl. It cures trichomoniasis with an unmatched high degree of effectiveness.

Flagyl is indicated for the treatment of trichomoniasis in both male and female patients and the sexual partners of patients with a recurrence of the infection provided trichomonads have been demonstrated by wet smear or culture.

Flagyl®

brand of (metronidazole)

Indications: For the treatment of trichomoniasis in both male and female patients and the sexual partners of patients with a recurrence of the infection provided trichomonads have been demonstrated by wet smear or culture. The oral form is indicated also for intestinal amebiasis and amebic liver abscess.

Contraindications: Evidence or history of blood dyscrasia, active organic disease of the CNS, the first trimester of pregnancy and a history of hypersensitivity to metronidazole.

Warnings: Use with discretion during the second and third trimesters of pregnancy and restrict to those pregnant patients not cured by topical measures. Flagyl (metronidazole) is secreted in the breast milk of nursing mothers. It is not known whether this can be injurious to the newborn.

Precautions: Mild leukopenia has been reported during Flagyl use; total and differential leukocyte counts are recommended before and after treatment with the drug, especially if a second course is necessary. Avoid alcoholic beverages during Flagyl therapy because abdominal cramps, vomiting and flushing may occur. Discontinue Flagyl promptly if abnormal neurologic signs occur. Exacerbation of moniliasis may occur. In amebic liver abscess, aspirate pus during metronidazole therapy.

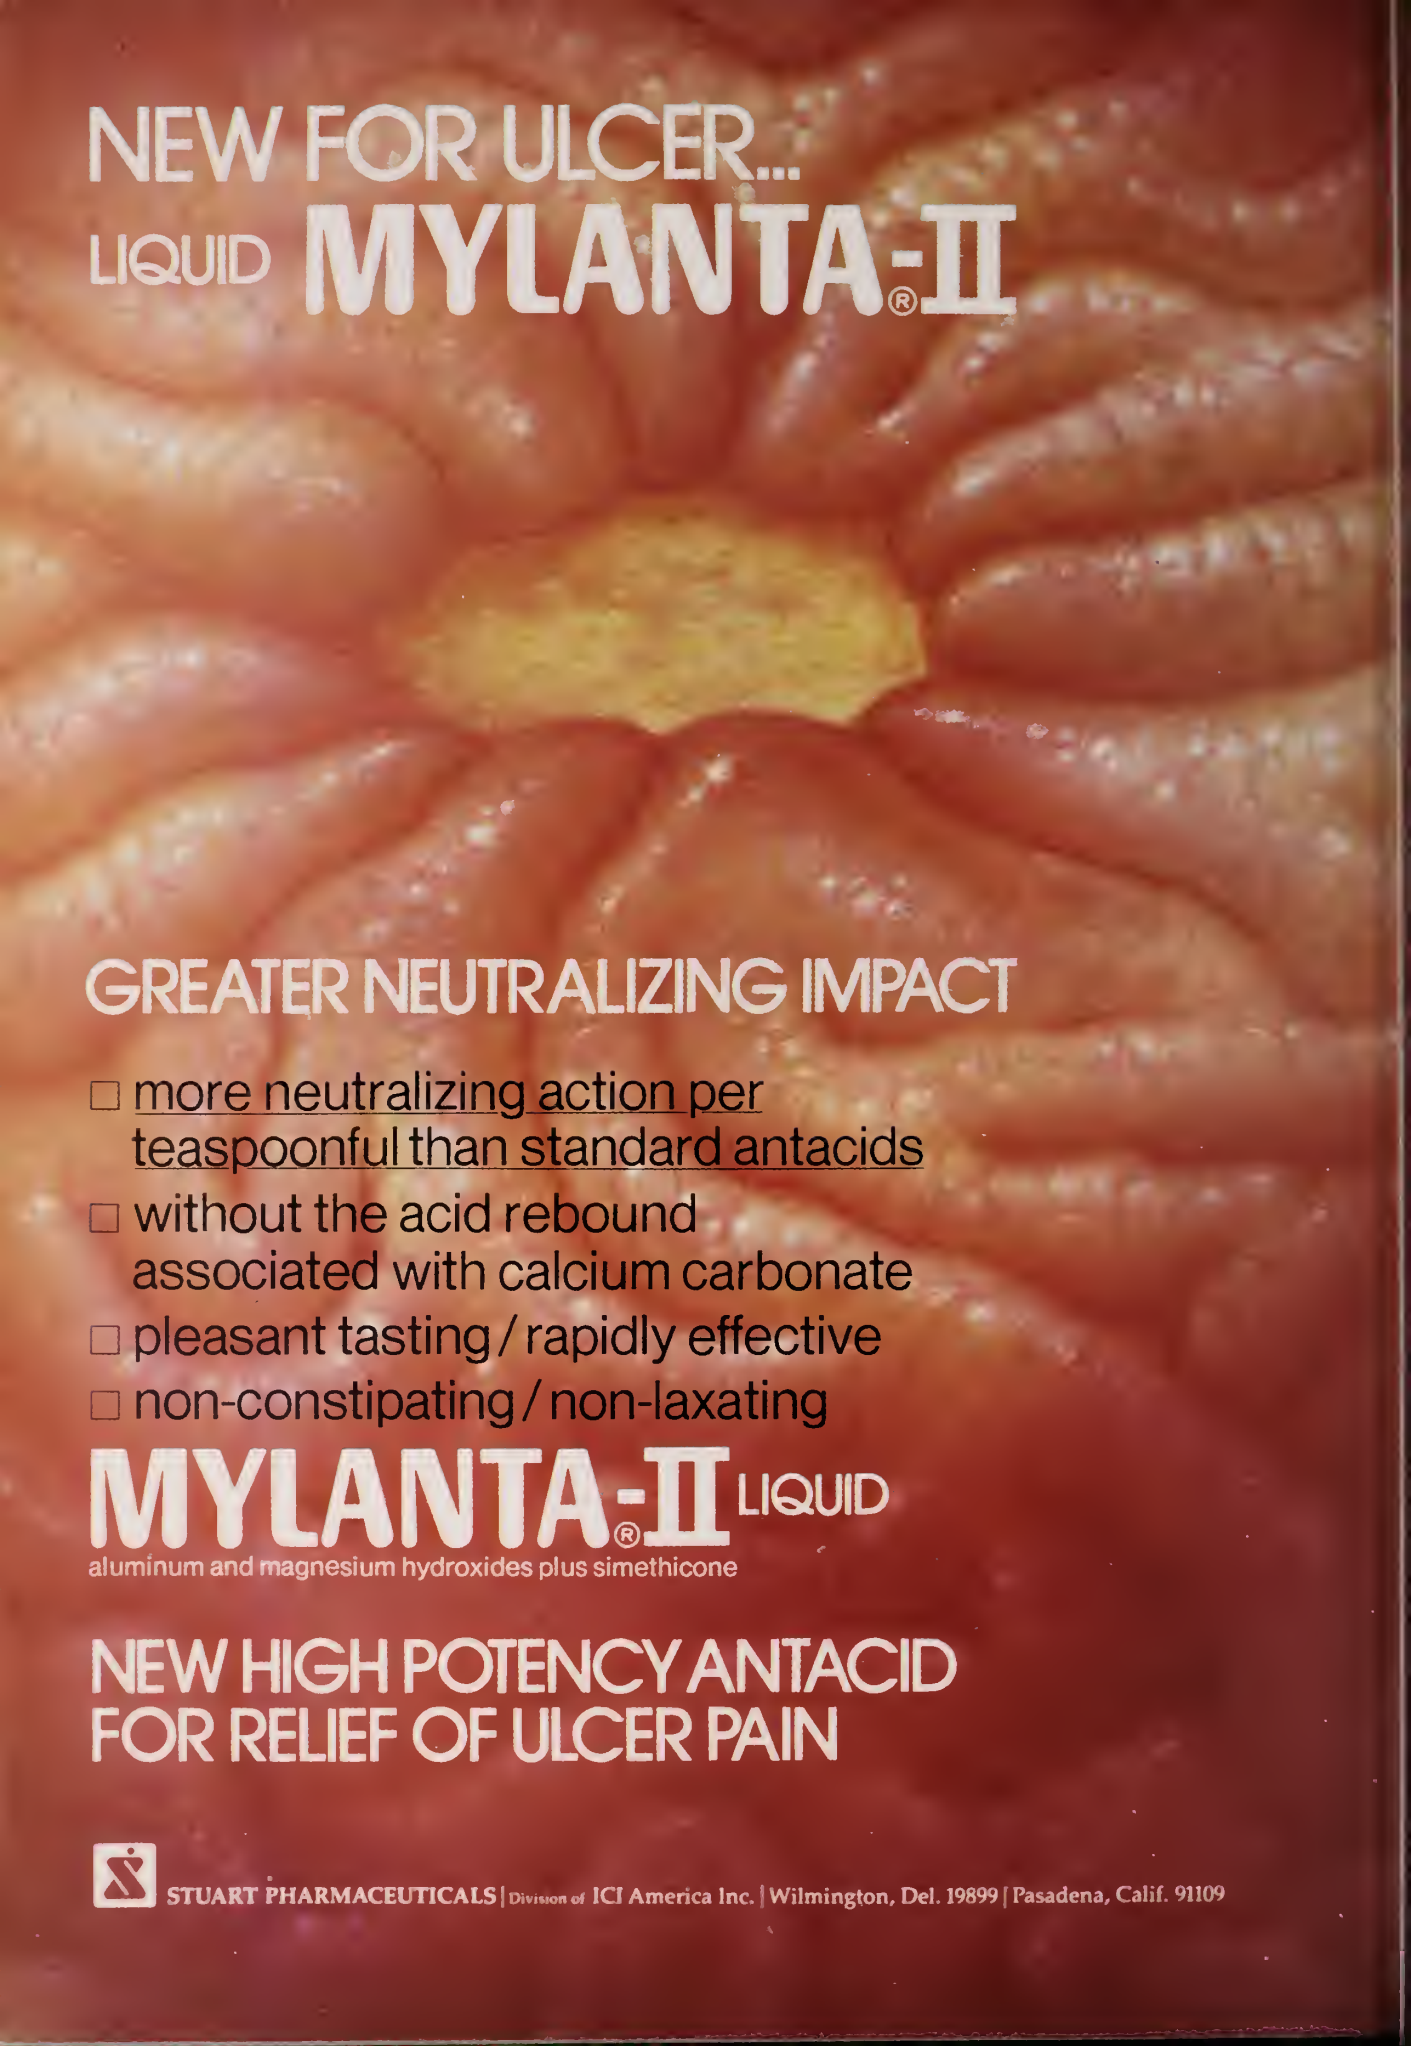
Adverse Reactions: Nausea, headache, anorexia, vomiting, diarrhea, epigastric distress, abdominal cramping, constipation, a metallic, sharp and unpleasant taste, furry or sore tongue, glossitis and stomatitis possibly associated with a sudden overgrowth of *Monilia*, exacerbation of vaginal moniliasis, an occasional reversible moderate leukopenia, dizziness, vertigo, incoordination and ataxia, numbness or paresthesia of an extremity, fleeting joint pains, confusion, irritability, depression, insomnia, mild erythematous eruptions, "weakness," urticaria, flushing, dryness of the mouth, vagina or vulva, pruritus, dysuria, cystitis, a sense of pelvic pressure, dyspareunia, fever, polyuria, incontinence, decrease of libido, nasal congestion, proctitis, pyuria and darkened urine have occurred in patients receiving the drug. Patients receiving Flagyl may experience abdominal distress, nausea, vomiting or headache if alcoholic beverages are consumed. The taste of alcoholic beverages may also be modified. Flattening of the T wave may be seen in EKG tracings.

Dosage and Administration

For Trichomoniasis. In the Female: One 250-mg. tablet orally three times daily for ten days. Courses may be repeated if required in especially stubborn cases; in such patients an interval of four to six weeks between courses and total and differential leukocyte counts before, during, and after treatment are recommended. Vaginal inserts of 500 mg. are available for use, particularly in stubborn cases. *When the vaginal inserts are used,* one 500-mg. insert is placed high in the vaginal vault each day for ten days and the oral dosage is reduced to two 250-mg. tablets daily during the ten-day course of treatment. Do not use the vaginal inserts as the sole form of therapy. *In the Male:* Prescribe Flagyl only when trichomonads are demonstrated in the urogenital tract, one 250-mg. tablet two times daily for ten days. Flagyl should be taken by both partners over the same ten-day period when it is prescribed for the male in conjunction with the treatment of his female partner.

For Amebiasis. Adults: For acute intestinal amebiasis, 750 mg. orally three times daily for 5 to 10 days. For amebic liver abscess, 500 to 750 mg. orally three times daily for 5 to 10 days.

Children: 35 to 50 mg./kg. of body weight/24 hours, divided into three doses, orally for ten days.



Dosage forms: Oral tablets 250 mg.
Vaginal inserts 500 mg.

Flagyl® (metronidazole)

Granulomatous Peritonitis Induced by Cornstarch Powder

THE REPORT by Hornung and Kremen* emphasizes that factors other than bacterial should be considered in the surgical ritual of scrubbing, gowning, and gloving. They advise scrupulous mechanical cleansing of dusting powder from surgical gloves as a part of the preparatory routine. Under certain circumstances absorbable dusting powder U.S.P.[1] (starch-derivative dusting powder), used throughout the world as a dry lubricant for surgical gloves, is implicated in the genesis of a nonspecific foreign body (granulomatous) inflammatory reaction of peritoneal surfaces after operations. A vague but definable clinical syndrome is recognized with an onset two to six weeks after laparotomy. At re-exploration, findings of a sterile peritonitis, ascites, miliary peritoneal nodules, and excessive peritoneal fibrosis are characteristic. Diagnosis is confirmed by microscopic identification of starch material in fluid exudate and within foreign body granulomata.

It is not possible from a single report to define clearly the magnitude of the problem, though the authors suggest that it is probably greater than recognized. During 1971 alone there were at least 15 additional cases reported in the medical literature,[2-7] I am aware of at least one additional documented case referred to the Mayo Clinic in the past year.

The product implicated is prepared by treating cornstarch with epichlorohydrin,[8] a compound described as a skin and kidney irritant and sensitizer.[9] The incorporation of not more than 2% magnesium oxide is said to help keep the starch derivative a fine powder. More recently this dusting powder has been made available in a sterile rapid-drying hand lotion to facilitate lubricating prepared hands just before donning gloves.

Little is known about the derivatives used and little progress has been made in developing safer substitutes; more basic information is needed. Meanwhile surgeons are urged to remember this potential complication, to clean the exterior of surgical gloves carefully with a wet towel, and to repeat cleaning when perforations require reglovving during operations.

W. Spencer Payne, M.D.
Rochester, Minnesota

Delayed Anemia

THE POSSIBILITY of unanticipated delayed anemia in hemolytic disease of the newborn is real, serious, and may be fatal. In this issue Strand and Polesky* remind us of two sources of error: failure to test all pregnancies for sensitization, and failure to measure serially hemoglobins of babies with mild hemolytic disease of the newborn. The suggested weekly intervals may not be frequent enough.

When one multiplies the above by the chances of technical laboratory error, secretarial error, garbled phone reports, unidentified loose papers, overloaded mental circuits and the always possible infectious or metabolic causation of neonatal icteric anemia, one is thankful that the authors had only nine cases to report.

In no other common clinical situation is diagnosis and management more dependent upon the accurate processing of laboratory measurements. Only methodical and diligent attention to detail can minimize the possibility of error.

An Unusual Complication of Cystourethrography

THE ARTICLE BY Cass and Vitko* in the April issue concerning unusual complications of cystourethrography describes a fairly significant complication of an ordinarily uncomplicated routine procedure done without incident every day in most hospitals. A plain catheter may become impacted, but is a less hazardous instrument than the Foley catheter which can be blown-up intraurethrally or in a ureteral orifice as has been sometimes reported.

The article by Kjelberg referred to in the discussion indicates that the incidence of technical complication is extremely low. This certainly does not mean that the complication rate cannot be reduced by improvement in the technician training programs.

The recommendation that the complication described in the case report could have been averted by introducing the catheter a shorter distance is certainly valid and perhaps this suggestion will be applied by someone reading this article.

Traumatic Luxation of the Testis

TRAUMATIC DISLOCATION of the testicle, described in this issue by Aquilina, is uncommon, perhaps because the mobility of the organ permits it to bounce away from most vulnerating forces. It is easily recognized if it can be established that the testis was normally placed before the injury. Replacement, either my manipulation or operation, should be simple if the patient's general condition permits. If delay is necessary, or if the abnormality is at first overlooked because of preoccupation with other injuries, fibrosis may prevent successful manipulation, but should not interfere with operation, based upon the principles of orchiopexy. If the epididymis has been avulsed without destroying the testicular blood supply, it should be sutured back in place, although sperm cannot thereafter be transplanted to their normal destination. If the blood supply to the testicle itself has been torn off, the organ had best be removed, since the presence of a small wad of scar tissue will afford the patient but little satisfaction. If the gonad is a solitary one, and the injury is fresh, one should consider cutting it into thin slices and inserting them into slits in a rectus muscle.

After any severe trauma to the testicle, the patient should be warned that atrophy may follow, least he attribute it to the treatment.

C. D. Creevy, M.D.,
Minneaoplis, Minnesota

Special Petrolatum Base
Neosporin® Ointment
(polymyxin B-bacitracin-neomycin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 5000 units; zinc bacitracin, 400 units; neomycin sulfate 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q. s.
In tubes of 1 oz. and ½ oz. for topical use only.

Vanishing Cream Base
Neosporin®-G Cream
(polymyxin B-neomycin-gramicidin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 10,000 units; neomycin sulfate, 5 mg. (equivalent to 3.5 mg. neomycin base); gramicidin, 0.25 mg., in a smooth, white, water-washable vanishing cream base with a pH of approximately 5.0. Inactive ingredients: liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax, purified water, and 0.25% methylparaben as preservative.
In tubes of 15 g.

NEOSPORIN for topical infections due to susceptible organisms, as in impetigo, surgical after-care, and pyogenic dermatoses.

Precaution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: Not for use in the external ear canal if the eardrum is perforated. These products are contraindicated in those individuals who have shown hypersensitivity to any of the components.

The Ruptured Disc Syndrome

To some, bony contriction of the spinal canal implies the syndrome of pseudoclaudication. In his paper published in the April issue, however, Ellison* describes a different syndrome of radiculopathy related to spurs and bony constriction of the entrances to the nerve root canals from the spinal canal. Roentgenograms of oblique views of the cervical spine often demonstrate spurs with clear evidence of narrowing of nerve root canals. Such narrowing in the lumbar area can conceivably be symptomatic, though the larger lumbar intervertebral foramina require hypertrophic changes of greater degree than in the cervical area. Hypertrophy of the ligamentum flavum usually takes place toward the midline in between the vertebral spines and the lamina posterior to the shelf of the ligamentum flavus. Although hypertrophy of the ligamentum flavum can indeed occur laterally, particularly in instances where the disk space is markedly narrowed, such hypertrophy is almost invariably posterior to the shelf of the ligamentum flavum where it cannot involve the nerve root.

While it is possible as indicated by the author's cases for radiculopathy to be produced by the combination of factors he cites, it should be remembered that this certainly is not a common finding, and we must be cautious about recommending surgery on this basis.

Reviewing a great many surgical reports of operations done throughout the country on patients with low back and leg pain who are referred to us with persistence of their symptoms reveals a high percentage of reports describing constriction of the nerve root canal, lumbar spondylosis with hypertrophy of the ligamentum flavum, hypertrophy of facet joints, and slightly bulging disks in combination with hypertrophied ligament. There is perhaps no surgical procedure which gives a better result than that performed for a truly extruded disk fragment. The reverse, however, is unfortunately true. Surgery performed for less clear pathologic changes often leaves scar tissue in and around the nerve roots and patients complaining of continuing pain similar to, or even worse, than they had experienced prior to the exploration.

Laparoscopic Sterilization*

Recent refinements in lighting, operative techniques, and instrumentation have revived laparoscopy (celioscopy) and it has become an important diagnostic and therapeutic tool in Gynecology. The panoramic view of the pelvis cannot be matched by culdoscopy. Its use in female sterilization has gained popularity because of low morbidity and short hospitalization.* In addition other operative procedures in the pelvis such as biopsy, cautery of small endometriomata, and lysis of adhesions have been described.

Pneumoperitoneum is produced with carbon dioxide or nitrous oxide gas and when general anesthesia is used, Anectine and endotracheal intubation with manual assistance of respiration is advisable. We have laparoscoped a number of patients using intravenous Valium and Nisentil with local abdominal block. This allows dismissal from the anesthesia recovery room after several hours, and assisted respiration is not necessary.

The major demand for laparoscopy at the Mayo Clinic has been for elective female sterilization, even though vasectomy is usually recommended to the couple seeking permanent sterilization.

We continue to remove bilaterally and confirm microscopically a small segment of fallopian tube near the uterine fundus and coagulate the two free ends, left after removal of the tube segment. Postoperative salpingography is not done because of possible tubal distension and production of patency by pressure.

As with most fallopian surgical procedures for sterilization, the possibility of patency re-establishing in the proximal stump of tube exists. However the failure rate must be low provided the round ligament or utero-ovarian ligament have not been mistaken for fallopian tube at the time of laparoscopy.

Laparoscopy is not a simple office procedure

as intimated by some writers. Complications associated with anesthesia and pneumoperitoneum occur. Bleeding and accidental bowel perforation present potential danger and require immediate laparotomy.

As with all surgical procedures, training and experience lessen the likelihood of complications due to errors in technique and improper patient selection. Laparoscopy will remain an important diagnostic tool for the gynecologist because it allows examination of the female internal genitalia that is more accurate than bimanual examination and less traumatic than laparotomy. A few patients will always benefit by such an examination. Its use in female sterilization is certainly acceptable but may be replaced by simpler methods in the future.

Spontaneous Healing of Interventricular Septal Defects

TRAUMATIC RUPTURE of the ventricular septum secondary to nonpenetrating chest trauma is an uncommon but well-recognized entity. In the April issue* Drs. Goldfarb and Wang present an interesting case of a 20-year-old man who developed a traumatic ventricular septal defect following severe chest trauma in an automobile accident. Attempted surgical closure of the defect approximately three months after the accident was apparently unsuccessful, but a spontaneous reduction in the degree of shunt was documented over the next two and a half years.

In their case no murmur of a ventricular septal defect was heard in the first five days after the accident, but one was present on re-evaluation two weeks later when the patient was admitted to the hospital with pulmonary edema. A delay in the appearance of a typical murmur is a frequent occurrence in traumatic ventricular septal defect and suggests that the septum, first contused, becomes necrotic and finally perforates. In one report describing a traumatic ventricular septal defect repaired 12 days after injury, the margin of the defect was found to be softened and necrotic.[1] Further evidence that this sequence of events occurs is the frequent association of either electrocardiographic changes of an anterior or inferior myocardial infarction, or the subsequent development of a ventricular or septal aneurysm, or both.

Such findings suggest that the surgical treatment of a traumatic ventricular septal defect should be similar to that of a postinfarction ventricular septal defect,[5] i.e., postponing repair for at least three months, and preferably longer, unless clinical deterioration occurs in spite of intensive medical therapy. The ideal time for repair of a ventricular septal defect after myocardial infarction, or traumatic ventricular septal defect, appears to be three and a half to six months on the basis of the work of Mallory and associates.[3] The high incidence of residual or recurrent shunts (six out of 12 patients in one review[1]) is similar to that for repair of postinfarction ventricular septal defect,[5] and suggests that operation should be delayed for fibrotic healing of the margins of the defect.

Most traumatic ventricular septal defects occur in the muscular portion of the septum near the apex, and more than one perforation is common. Single perforations of the septum may appear multiple, when viewed from the right ventricle, because of the dense network of trabeculae at the apex. Excision of the trabeculae before attempting closure of the ventricular septal defect aids in achieving an accurate repair.

If a ventricular aneurysm is present in the left ventricle, it is desirable to incise it and repair the septal defect from the left side, as suggested by the authors. The aneurysm can then be resected as indicated during closure of the ventriculotomy.

The authors propose waiting for spontaneous healing of the septal defect, on the basis of their case and one recently reported in the literature,[4] as a nonoperative alternative to surgical closure. Spontaneous healing does occur, but the percentage of traumatic ventricular septal defects that heal spontaneously is probably small. On the basis of these two cases, followed three and a half years and eight years respectively, the time for spontaneous healing would appear to be several years. Both of these patients still have residual shunts. Of the nine patients treated medically since surgical means of closing the defect have

*See page 325.

become available, five have died,[1] two from cardiac arrhythmia, one from multiple injuries, and two from a persistent large left-to-right shunt. No deaths have yet been reported among the 12 patients treated surgically.[1] Our preference is, therefore, surgical closure of all large traumatic ventricular septal defects which still appear to be hemodynamically significant after observation for a suitable period of time, four to eight months. Further experience in the treatment of these lesions, combined with careful hymodynamic assessments such as those reported by Goldfarb and Wang, will be needed before the best plan of management can be definitely known and agreed upon.

Florida to Issue Medical Licenses by Endorsement

EFFECTIVE SEPTEMBER 1, 1971, for the first time in history, the Board of Medical Examiners of Florida may issue licenses by endorsement to practice medicine and surgery in Florida. An amendment to the Medical Practice Act of Florida, enacted by the 1971 legislature allows issuance of licenses by endorsement to those M.D.'s who have been certified by the National Board of Medical Examiners or the Federation Licensure Examination (FLEX) within a period of eight years preceding the date of application for license by endorsement.

Since the effective date is September 1, 1971, this means that an M.D. must have been certified by the National Board of Medical Examiners since September 1, 1963, in order to initially be eligible for licensure by endorsement. As far as other state licensure examinations are concerned, this amendment only applies to those states who use the Federation Licensure Examination (FLEX) as their licensure examination.

In the case of foreign medical graduates, this does not eliminate the requirement that the M.D. have papers of first intention of citizenship and a minimum of one year's residency in the United States and the Educational Council for Foreign Medical Graduates Certificate of proficiency. A very important feature of the amendment is the provision that a physician who receives a license by endorsement in Florida must practice in the state within a period of three years for a minimum period of one year. If he does not do this the license will become null and void. Service in the armed forces is exempt during these three years, but internship or residency time is not exempt.

Long sentences in a short composition are like large rooms in a little house.—Shenstone.

Specifically formulated with
vitamins and minerals important
in the treatment of anemia

PHASE 1
Enhanced Absorption

Each tablet provides 115 mg elemental iron as the highly absorbable ferrous fumarate *plus* 600 mg of Vitamin C.

PHASE 2
Erythrocyte Formation

Each tablet provides Vitamin B_{12} (25 mcg) and Folic Acid (1 mg) to replace deficiencies.

PHASE 3
Premature Hemolysis

Each tablet provides Vitamin E, which may be involved in lessening red blood cell fragility.

For common anemias
as well as problem ones

TriHEMIC™ 600
HEMATINIC TABLETS

Tri-Phasic Hematinic with 600 mg Vitamin C PLUS Vitamin E

Each tablet contains:	
Vitamin C (Ascorbic Acid)	600 mg.
Vitamin B_{12} (Cobalamin Concentrate, N.F.)	25 mcg.
Intrinsic Factor Concentrate	75 mg.
Folic Acid	1 mg.
Vitamin E (*d*-Alpha Tocopheryl Acid Succinate)	30 Int. Units
Elemental Iron (as present in 350 mg. of Ferrous Fumarate)	115 mg.
Dioctyl Sodium Sulfosuccinate U.S.P.	50 mg.

Dosage: One Tablet Daily.
Available in Bottles of 30 Tablets.
On Your Prescription Only.

Precautions: Some patients affected with pernicious anemia may not respond to orally administered Vitamin B_{12} with intrinsic factor concentrate and there is no known way to predict which patients will respond or which patients may cease to respond. Periodic examinations and laboratory studies of pernicious anemia patients are essential and recommended. If any symptoms of intolerance occur, discontinue drug temporarily or permanently. Folic acid, especially in doses above 1 mg. daily, may obscure pernicious anemia, in that hematologic remission may occur while neurological manifestations remain progressive.

Adverse Reactions: G.I.: nausea, vomiting, diarrhea, abdominal pain. Skin rashes may occur. Such reactions may necessitate temporary or permanent changes in dosage or usage. Allergic sensitization has been reported following both oral and parenteral administration of folic acid.

TriHEMIC™ 600
HEMATINIC TABLETS

Tri-Phasic Hematinic with 600 mg Vitamin C PLUS Vitamin E

Specifically formulated with vitamins and minerals important in the treatment of anemias, plus a stool softener to counteract the constipating effects of iron

Laboratory Letter

Screening for β- Hemolytic Streptococcus In the Throat

Charles W. Jarvis, M.D.*
St. Paul, Minnesota

IDENTIFYING SORE throat of group A, beta hemolytic streptococcus is difficult enough so that many laboratory procedures have been devised to aid the clinician. The best procedure involves culturing material from the oropharynx on blood agar; isolating a small colony that produces a zone of clear hemolysis; examining the colony by gram stain to rule out other beta hemolytic organisms; and finally subculturing followed by serological identification of the Lancefield group.

This method is time consuming and expensive for the usual sore throat. Another method has received publicity because of its rapidity. This is the fluorescent antibody tagging of four-hour-old cultures. Unfortunately this is not conveniently available for most physicians and their patients.

There remains a third method, really just a simplified version of the first, that requires a minimum of handling, equipment, bacteriological expertise, and time, This method has become popular in physicians' offices and outpatient departments because it is rapid and inexpensive. The procedure is as easy for the physician in a one or two girl office as for the physician in the big clinic and as useful to a small town generalist as to the big city pediatrician.

Material

Blood Agar Plates

Use trypticase soy agar with 5-10% sheep blood in sterile, disposable plastic Petri plates. Sheep blood is preferable to human (outdated blood-bank) blood because the latter may inhibit the growth of streptococci. Ready-made plates are available from numerous commercial sources, but since freshness is important, many physicians purchase a few plates at a time from the nearest hospital bacteriology laboratory where a high use rate usually will guarantee that the agar will not dry out before it is used.

Incubator

There are a number of small incubators available from laboratory supply houses. Be sure there is adequate temperature control because these organisms grow best at a temperature slightly below 37°C.

Cotton tipped applicators.

Bacitracin discs, 0.04 unit†

Procedure

1. Swab the inflamed area of the pharynx. Try to avoid contamination by the tongue and saliva.
2. Rub the applicator over the surface of the blood agar, using overlapping strokes (Figure 1). Use about half the plate. If supplies are scarce, two patients can easily occupy one plate.

---

*From the Department of Pathology, Childrens Hospital, St. Paul, Minnesota.
Correspondence to: Childrens Hospital, 311 Pleasant, St. Paul, Mn. 55102
†Taxo A Sensi-Disc, BBL, Cockeysville, Md.

Fig. 1—Rub the throat swab over the blood agar in overlapping strokes.

Fig. 2—Place a 0.04 unit bacitracin disc in the center of the area which has been swabbed.

Fig. 3—Positive screening culture. The dark ring around the black disc represents a zone of unhemolyzed blood where bacitracin-sensitive bacteria can not grow. They grow well elsewhere and produce clear (beta) hemolysis. The bacitracin-resistant organisms which grow in the dark ring do not produce hemolysis.

Fig. 4—Negative screening culture. The homlytic bacteria grow well right up to the bacitracin disc because they are resistant to the action of the bacitracin.

3. Place a bacitracin disc on the swabbed surface and push gently to be sure it has made firm contact with the agar (Figure 2).
4. Incubate at 35-37°C for 18 hours. The 18 hours allows plenty of time for good growth and hemolysis to take place but longer times (such as from Saturday noon to Monday morning) are acceptable.

Interpretation

Read the plate for bacitracin sensitivity and beta hemolysis (Figure 3). Remember that the group A, beta hemolytic streptococci form small, white colonies which produce clear (beta) hemolysis in the blood, and will not grow to within 15-20 mm of a bacitracin disc. Green (alpha) hemolysis indicates some other streptococcus or pneumococcus. Other colonies with beta hemolysis, but which are resistant to bacitracin, will be non-group A streptococci, hemophilus, or even colon bacilli. Any of these will produce a picture like that in Figure 4.

There you have it. There are many refinements that you can add, of course, but this simple system will give you an answer—an answer obtained with minimal expenditure of patient funds and physician effort, but one obtained rapidly enough so that you can wait for it before deciding that a 10-day-long course of penicillin is indicated.

Trained Laboratory Technicians

For many years it has been difficult for physicians to hire adequately trained laboratory technicians to work in their offices, especially if the physican practiced alone or in a small group where the volume of lab work was not great, or practiced in a rural community when the social opportunities were limited. In an attempt to solve this problem, the Minnesota Society of Clinical Pathologists and the Minnesota Society of Medical Technologists formed a Medical Laboratory Assistants (MLA) Board to help start training courses for medical laboratory assistants, and to guide the education of these students. The Board is composed of pathologists, medical technologists, and certified laboratory assistants, all of whom serve without pay. At the present time, there are five schools which have been inspected and approved by this Board. They accept upper level high school graduates for training periods varying from 12 to 24 months. Their courses include chemistry, urinalysis, hematology, serology, blood banking, EKG, and some basic bacteriology. In addition, they learn basic quality control procedures and are constantly reminded that the patient is the only reason for the profession's existence. The graduates take a certifying examination given by the MLA Board. The young adults who graduate from the courses in these five schools are well trained and capable of doing the basic tests needed in most physicians offices.

More information on the MLA courses or on the availability of graduates contact one or more of the following sources directly.

Fracture Conference

Birth Fractures*

ANTHONY J. BIANCO, M.D.,† ALLEN P. SCHLEIN, M.D.,† ROBERT L. KRUSE, M.D.†
EINER W. JOHNSON, JR., M.D.†

Robert L. Kruse, M.D.:

Osseous injuries in the newborn are usually secondary to birth trauma, congenital fragility, osteogenesis imperfecta, or congenital pseudarthrosis of the tibia. We will discuss the problem of birth trauma.

Time may be an important factor in delivering an infant in breech presentation, and the obstetrician may deliberately fracture the clavicle or the humerus in problem deliveries. The clavicle also may be broken by a shoulder dystocia, especially when the infant is unusually large. Osseous injuries obviously are of less consequence than prolonged cerebral anoxia. About three fourths of birth fractures occur in breech presentation. In the usual case, the mother is a primipara and, surprisingly, the infant is not extremely large.

With proper diagnosis and adequate treatment, the prognosis for these injuries should be excellent. The infant has a marked ability to form callus and to heal fractures. Nonunion is practically unheard of, and union occurs rapidly. Angulation is usually remodeled within the first two years of life.[1]

The diagnosis of a birth fracture is easy if one knows the features of skeletal development and the manner in which the periosteum and the soft tissue react to trauma. Fractures of an extremity are usually complete and have considerable displacement. The first evidence of injury may be the tumor of callus formation, appearing one to two weeks postpartum, but callus formation can often be seen on roentgenograms as early as the fifth day.

Obstetric palsy can be confused with clavicular or humeral fracture or can mask a fracture in this area.[2] The shaft of the long bones is involved more commonly than the epiphysis. Clavicular fracture is the commonest injury. In Madsen's study[3] of 105,119 newborns, 726 fractures involved the clavicle.

*Fracture Conference, July 7, 1969.

†From the Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

Types of Injuries

Clavicular fracture usually involves the middle third of the shaft and usually is of the greenstick type (other types of birth fractures are usually complete fractures). This fracture is generally secondary to digital pressure on the clavicle during delivery and to attempts to deliver the aftercoming head in a breech presentation. In a vertex presentation, traction or shoulder dystocia causes fractures in this region. Treatment may not be necessary, but the infant is often placed on its back with a small folded towel between its shoulder blades.

Humeral fractures usually occur in the middle third of the shaft and are either transverse or spiral. The anterolateral angulation of the proximal fragment is commonly caused by the deltoid muscle. This is because the fracture is just below the insertion of the deltoid on the humeral shaft. This injury can be complicated by radial palsy, but this generally disappears within six to eight weeks. The mechanism here is usually traction on the extended arms in breech presentations. Also, in cephalic presentations, fracture of the humerus may be caused by the use of axillary traction to disengage an impacted shoulder. Treatment again should not be strenuous. The arm can be abducted on an axillary pad and also strapped to the chest. This axillary pad brings the distal fragment into abduction with the proximal fragment. Shortening and angulation up to 40° to 50° will be corrected within two years.[1]

Femoral shaft fractures occur in the middle third and are transverse. The proximal fragment is abducted and flexed by the psoas muscle so that it will be at right angles to the distal fragment. This injury is caused by torsion on the legs in breech delivery. Also, groin traction or bringing the leg down from the extended breech position can result in fractures of the femur. This fracture should be treated by Bryant's traction which will bring the distal fragment into a flexed

position and in relationship to the proximal fragment. Overriding of 1 cm and 20° of posterior angulation are reported by Madsen[3] to be acceptable.

Periosteal stripping and epiphyseal displacement are the last injuries which we will discuss. Periosteal stripping is manifested by pain and swelling in the traumatized area, associated initially with normal roentgenograms. After five to seven days, subperiosteal calcification appears on the roentgenogram. If injury to the periosteum is associated with epiphyseal displacement, the greatest mass of subperiosteal calcification will be seen in the area of the epiphysis. Snedecor and Wilson[4] found that in approximately 6% of 50 consecutive breech deliveries there was subperiosteal calcification within five to seven days after birth.

Epiphyseal displacement usually occurs in the distal part of the femur or the upper or lower part of the humerus. Trauma in relationship to breech extraction is the usual cause. Diagnosis is made by physical examination, often associated with a history of the bone audibly cracking or the shaft giving way during delivery. Ferguson[5] reported that all epiphyseal displacements are associated with a fracture (triangular) of the metaphysis—the so-called Thurston-Holland sign which may be seen on the roentgenogram at birth. Displacement is usually absent or minimal but, if displacement occurs, gentle manipulation and splinting is the treatment of choice.

The lower femoral epiphysis is roentgenographically evident at birth and, if it is displaced, it usually will be so posteriorly. Treatment is by Bryant's traction for two to three weeks. If manipulation is necessary, one has to be careful to avoid compression of the popliteal vessels. If slipping of the distal femoral epiphysis is not corrected at birth, the hematoma will form a new shaft posterior to the original shaft and the latter will be absorbed. Remodeling of this deformity will take two to three years, but it will correct itself.

Upper femoral epiphyseal displacement is a rare birth injury. When it occurs it is also treated by Bryant's traction. Baron and associates[6] recommended spica casting for six weeks, but I do not think that this is necessary. I believe Bryant's traction to be satisfactory treatment for most femoral injuries. As coxa vara and degenerative changes occur secondary to this type of injury, the parents should be informed of possible complications.

Lower and upper humeral epiphyseal displacements are treated primarily by sling immobilization, with the elbow in 90° of flexion.

Illustrative Cases

Allen P. Schlein, M.D.:

We have three simple cases to present, demonstrating some of the things that Dr. Kruse has discussed.

The first patient was born here in December 1967, without any specific history of difficulty occurring during delivery. He was circumcised and dismissed from the hospital as a normal, newborn infant. However, on December 30, 12 days after birth, he was returned to the emergency room by his mother because she had found a large, mildly tender mass over his left clavicle. Careful questioning of the mother revealed that the child had had a bruise in the area shortly after delivery. Roentgenograms taken in the emergency room revealed a healing fracture of the left clavicle (Figure 1). This simple case was chosen to show that the first sign of a birth fracture can be the large, exuberant callus found two weeks after the injury.

Fig. 1 (Case 1). Callus is present secondary to healing of fractured left clavicle.

The second patient had been born after a difficult breech delivery, and the obstetrician immediately recognized the fact that the humerus had been fractured (Figure 2). The child was placed in a swathe to hold the arm to the side. There

Fig. 2 (Case 2). Transverse fracture of midshaft of right humerus of newborn.

was no neurocirculatory problem.

Anthony J. Bianco, M.D.:

Dr. Mess, do you think this fracture would be difficult to immobilize?

Charles F. Mess, M.D.:

I think it would. All the parts are so small that it would be difficult to wrap the child. There also are many problems in the care of the child, such as bathing, diapering, and so forth. However, I would try to immobilize it close to his side as was mentioned.

Mark B. Coventry, M.D.:

I would disagree. I would leave it strictly alone and would not try to strap it, as it then becomes virtually impossible to bathe the child. We all know that it will heal perfectly if we leave it strictly alone, so why strap it?

Dr. Bianco:

But don't you think that, when the child is fussy for the first few days, it is a simple matter to immobilize the fracture at the side until the region needs cleansing?

Dr. Schlein:

After this child was sent home, he was never even returned for another roentgenogram and he never had any difficulty with the arm.

Dr. Mess:

Have radial nerve injuries ever been reported?

Dr. Bianco:

I personally have never seen one in a fracture in the newborn. I think it would be hard to diagnose and is probably missed.

Henry N. Goodwin, M.D.:

If you just left these fractures alone, would not the chance of radial nerve injury be increased?

Dr. Bianco:

You would think so, but letting them alone does not seem to increase the number of radial nerve injuries.

Dr. Schlein:

The third case demonstrates a slightly different problem in a breech delivery. This baby weighed nine pounds 11 ounces at birth here in February 1966. The mother was known to be diabetic, and this was her first child. Labor was slightly prolonged and delivery was reported as difficult. It was noted that the child did not move its left arm, and a roentgenogram taken at that time showed a transverse fracture of the left humerus (Figure 3-A). This was treated by binding the arm to the chest with a swathe for a period of three weeks. However, a roentgenogram made nine days after injury (Figure 3-B) showed surprisingly little callus; but roentgenograms one month after injury (Figure 3-C) showed that the fracture was healing well with minimal treatment.

Joseph M. Janes, M.D.:

I would like to mention a case in which a boy, whom I saw when he was nine years old, had had a birth fracture of the midshaft of the femur.

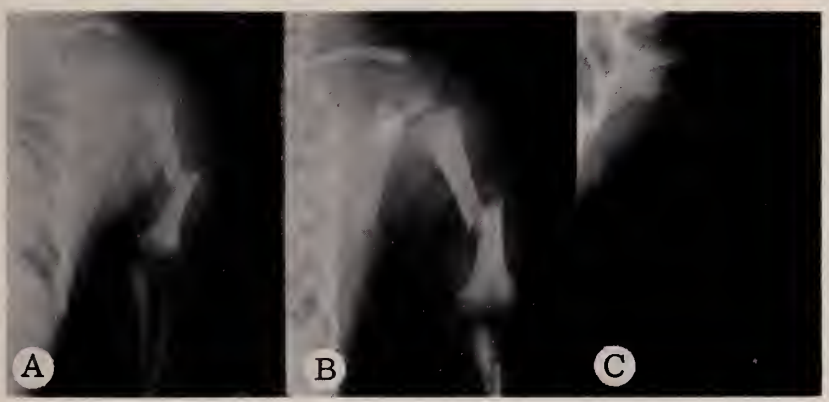

Fig. 3 (Case 3). (A) Transverse fracture of left humerus, at birth. (B) At nine days after injury. (C) Healing fracture approximately one month after injury.

It was in good position, but the extremity was shortened one and one-half inches. Obviously not all these problems correct themselves.

Dr. Bianco:

That is a good point. We are talking about birth fractures in otherwise normal infants, not about osteogenesis imperfecta or congenital pseudarthrosis of the tibia. We know that these fractures should heal in rapid fashion regardless of the treatment. I was going to ask the consultants if they ever have seen a nonunion of a birth fracture.

Dr. Coventry:

I may have such a case. The child was not born here, but the history from the mother and the local physician indicates that it probably was a birth fracture. Of all things, it was a clavicular fracture, and it did not unite. We have roentgenograms covering two years, from at least three months postpartum. The child had no characteristics of congenital pseudarthrosis. This was a strange case, and I had to do a bone graft when the child was two years old. It did go on to union. This conceivably could have been a postpartum fracture.

A gratifying announcement about Empirin® Compound with Codeine

You may now specify up to five refills within six months when you prescribe Empirin Compound with Codeine (unless restricted by state law).

It is significant in this era of increased regulation, that Empirin Compound with Codeine has been placed in a less restrictive category. You may now wish to consider Empirin with Codeine even more frequently for its predictable analgesia in acute or protracted pain of moderate to severe intensity.

Empirin Compound with Codeine No. 3 contains codeine phosphate* (32.4 mg.) gr. ½. No. 4 contains codeine phosphate* (64.8 mg.) gr. 1. *(Warning—may be habit-forming.) Each tablet also contains: aspirin gr. 3½, phenacetin gr. 2½, caffeine gr. ½.

When you select this familiar antibiotic for IV infusion you have available a broad dosage rang that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

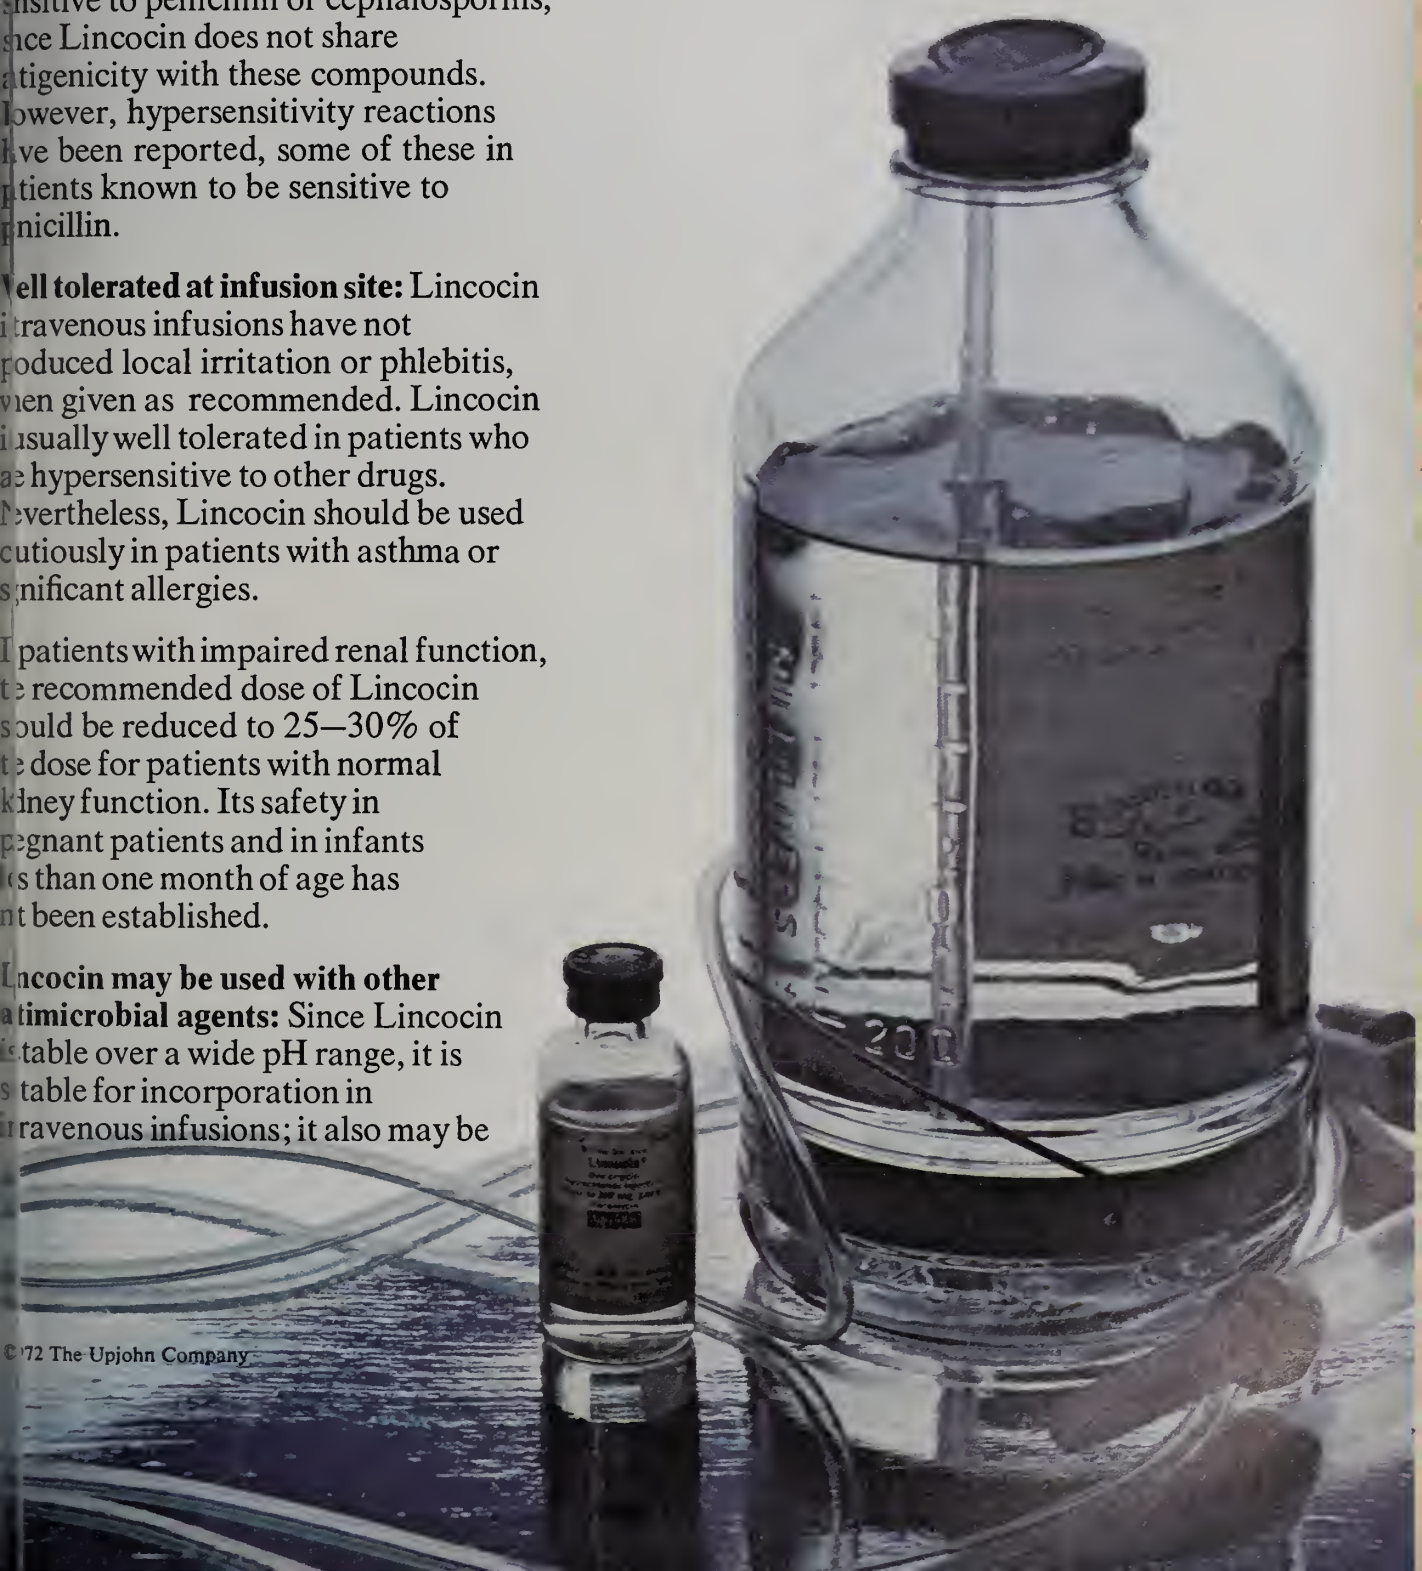
In usual IV doses, Lincocin (lincomyci hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water. But when 4 grams or more per day is given, Lincocin should be diluted in nc less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

fections caused by susceptible strains
pneumococci, streptococci, and
aphylococci, including penicillin-
sistant strains. Staphylococcal strains
sistant to Lincocin (lincomycin
ydrochloride, Upjohn) have been
covered. Before initiating therapy,
lture and susceptibility studies should
performed. Lincocin has proved
luable in treating patients hyper-
nsitive to penicillin or cephalosporins,
nce Lincocin does not share
tigenicity with these compounds.
owever, hypersensitivity reactions
ve been reported, some of these in
tients known to be sensitive to
nicillin.

ell tolerated at infusion site: Lincocin
travenous infusions have not
oduced local irritation or phlebitis,
nen given as recommended. Lincocin
usually well tolerated in patients who
e hypersensitive to other drugs.
evertheless, Lincocin should be used
utiously in patients with asthma or
nificant allergies.

patients with impaired renal function,
e recommended dose of Lincocin
ould be reduced to 25—30% of
e dose for patients with normal
dney function. Its safety in
egnant patients and in infants
s than one month of age has
t been established.



ncocin may be used with other
timicrobial agents: Since Lincocin
table over a wide pH range, it is
table for incorporation in
travenous infusions; it also may be
administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

©'72 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn)

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatm *Skin and mucous membranes*—Skin ra urticaria, vaginitis, and rare instances o foliative and vesiculobullous dermatitis been reported. *Liver*—Although no direc lationship to liver dysfunction is establis jaundice and abnormal liver function (particularly serum transaminase) have observed in a few instances. *Cardiovasc* —Instances of hypotension following pa teral administration have been repo particularly after too rapid IV admini tion. Rare instances of cardiopulmonar rest have been reported after too rapi administration. If 4.0 grams or more ad istered IV, dilute in 500 ml of fluid administer no faster than 100 ml per h *Special senses*—Tinnitus and vertigo been reported occasionally. *Local reac* —Excellent local tolerance demonstrate intramuscularly administered Linc (lincomycin hydrochloride). Reports of following injection have been infreq Intravenous administration of Lincoc 250 to 500 ml of 5% glucose in dist water or normal saline has produce local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500* Capsules—bottles of 24 and 100. *S Solution, 300 mg per ml*—2 and 10 ml and 2 ml syringe. *Syrup, 250 mg per* —60 ml and pint bottles.

For additional product information, co the package insert or see your Up representative.

Fetal Monitoring*

A Retrospective Evaluation

DAVID L. HILL, M.D.†

MODERN OBSTETRICS has come to recognize the dynamic nature of labor and its inherent stresses on the fetus. With electronic advancement, fetal monitoring has become available to all major obstetrical services, and much enthusiasm has been generated for this method of evaluating fetal stress. Because many of the variations in fetal heart rate and intrauterine pressure are only detectable by constant monitoring, many presume that best obstetrical care can be given only with this method of detecting early fetal stress and determining which of the variations are benign. The questions raised at this point are many, but a few warrant emphasis. What is the expenditure of time required by the staff to operate a monitoring unit? How often is the monitor able to add to information already known by standard observation methods? How difficult are records to interpret? How reliable is the monitor in predicting distress? Is fetal monitoring a practical method for all hospitals at this point in its development?

*Paper and discussion presented to the Minnesota Society of Obstetrics and Gynecology, April 24, 1971, Duluth, Minnesota.

†Department of Obstetrics and Gynecology, Hennepin County General Hospital, Minneapolis, Minnesota.

Materials and Method

The present study is a review of the first one hundred patients monitored at Hennepin County General Hospital. From March, 1970, to January, 1971, 1,524 infants were delivered at the hospital. Of these 100 or 6.5% were monitored. The reasons for monitoring are listed in Table 1. The

Meconium Stained Fluid (14)	9	2	5

*Total patients in group in parenthesis.

Corometrics FMS-101 Unit* was used. Residents in obstetrics hooked up the monitor and followed these patients. The results were used for clinical decisions. All records were reviewed and classified after delivery. Variant patterns of both fetal heart rate and intrauterine pressures were compiled in various categories according to Caldeyro-Barcia[1] and Hon[2] (Table 2). The outcome of each labor is very difficult to evaluate, but the parameters chosen were fetal distress (defined as tachycardia, late decelerations, or severe variable decelerations), low Apgar scores (< 4 at 1 minute or < 7 at 5 minutes), and cesarean section rate.

Of special interest was a review of obstetric statistics comparing Hennepin County General Hospital with Northwestern Hospital. Northwestern Hospital is a private Minneapolis hospital with 25% fewer deliveries than General Hospital. All patients at Northwestern Hospital were followed and delivered by obstetricians but fetal monitoring equipment was not available. Comparison of perinatal mortality, cesarean section rate and low Apgar scores in these two hospitals are made in Table 3. Also included for comparison are the statistics for the year immediately preceding the installation of monitoring equipment at General Hospital.

TABLE 3

†Information not available.

Results

Conclusion must be drawn with caution from such small groups as these with so many variables. The limitations in the interpretation of retrospective statistics must also be kept in mind.

Personnel and Interpretation

At General Hospital, there is 24-hour staffing by residents in obstetrics. As the monitoring program progressed, it became obvious that this full-time coverage was absolutely necessary. Not only do problems arise at any hour of the day, but there must be someone with experience to apply and maintain the equipment, as well as interpret the records. Interpretation of records is not a simple matter, because changes are frequently combinations of different patterns. Attempts to use the monitor failed in 14% of the patients, due to faulty scalp electrodes or inability to pass the intrauterine catheter.

Fetal Distress by Fetal Heart Rate

Parameters of fetal distress occurred in 46% of the total patients. The most frequently observed parameter was tachycardia. It responded to treatment by position change and maternal oxygen. If oxytocin was being administered, it was decreased or discontinued. The other types of fetal distress also responded to treatment in most cases. Only four patients were finally delivered by cesarean section.

The majority of irregular fetal heart rate patterns were variable decelerations, a variation that can be diagnosed only by continuous monitoring. Because this abnormality is known to be a benign pattern, except in its severest form, operative intervention was prevented in several cases.

Abnormal Contraction Patterns

In the total group of 100 patients, 60% received intravenous dilute oxytocin for stimulation or induction of labor. This must be considered when interpreting the results to follow.

Hypertonus was observed in 30% of the group, many times in a very subtle way that would not have been detected except by a monitoring service. Clinically a significant increase in the baseline pressure was not always accompanied by painful or palpably hard uterine contractions. On one occasion, an oxytocin overdosage was detected immediately with no resultant harm to the fetus. This infrequent, but real situation, is safeguarded by the monitor. On the other hand, oxytocin can be increased with safety more rapidly to an effective level saving time with inductions. An earlier diagnosis of failed induction can also be made if exact contraction patterns are known.

Incoordinate contraction patterns were observed in 38% of the patients studied. Monitoring makes this pattern more easily recognized, and appropriate treatment can be given earlier.

Low Apgar Scores

A low Apgar score was defined as less than four at one minute or less than seven at five minutes. By these criteria, fourteen infants had a low Apgar score in the study. Only 50% of

*Corometrics Medical Systems, North Haven, Connecticut.

these were predictable by the monitoring record because the record was not available up to the time of delivery. It is generally accepted that the fetus can get in or out of trouble within 20 to 30 minutes.

Of the fourteen infants, eight were delivered by cesarean section. Because of this, there were additional factors that could have contributed to the low Apgar scores, especially at one minute.

Cesarean Sections

Fifteen patients were delivered by cesarean section. In most of the sections the deciding factor for operative intervention was the contraction pattern. In four other cases the fetal heart rate indicated fetal distress. These findings tend to shift the emphasis in monitoring from the fetal heart rate pattern to the uterine contraction pattern. This is logical because fetal distress is almost always related to stress secondary to the uterine contractions.

Hospital Comparisons

If the statistics at General Hospital are compared (Table 2) for the year before and the year of monitoring, the difference is striking. Although many factors are involved, one concludes that monitoring may have played an important role in decreasing the corrected perinatal mortality by 50%. The similarity of cesarean section rates may indicate better selection for operative intervention.

When the applicability of fetal monitoring is considered for any particular obstetrical service, the statistics of that service must be reviewed. Some services have results that would be difficult to improve. This seems to be the case at Northwestern Hospital but the price paid is a 10% cesarean section rate. The expenditure of time and money for monitoring in this situation cannot be justified.

Discussion

In the evaluation of a new method or technique, it is important to remember the basic principles involved. Monitoring is simply a graphic display of the stress of uterine contractions on the fetus, which may lead to hypoxia and acidosis, resulting in changes in the fetal heart rate. In other situations, contractions exert to pressure on the cord or head which leads to changes in the fetal heart rate. This review indicates the frequency of abnormal contraction patterns, and helps to emphasize the importance of intrauterine pressure. Not enough emphasis has been placed on contraction patterns, which leads to a pessimistic viewpoint in thinking that external monitoring will ever have anything to add, except in the area of stress tests.

Conclusion

Fetal monitoring gives the obstetrician more objective data to assist him in making clinical judgments. It is also an aid in teaching. In some circumstances, monitoring appears to definitely improve the statistical outcome of pregnancy. There are some[3] skeptics who suspect that the major factor in improvement on statistics results from the closer attention given by the staff.

For some obstetrical services, the time, training and expense, make monitoring impractical or impossible to obtain and operate efficiently. For others, monitoring may be unnecessary.

At the present time fetal monitoring is confined to the teaching obstetrical service. It may become applicable to the population at large only when obstetrical services combine to make an obstetrical intensive care unit a reality.

Meetings

American Medical Writers Association

The North Central Chapter will sponsor a workshop "To Improve Medical Writing," May 13, 1972, Mayo Building, 15th Floor Lecture Hall, Rochester. Fee: $25.00. Registrations to: Eleanore Clappier, Proceedings Office, Mayo Clinic, Rochester.

Discussion

Donald W. Freeman, M.D.:

Dr. David Hill has taken a look at some of the problems involved in electronic fetal monitoring together with the expected yield, and has set forth some of the arguments for and against its application in private non-teaching hospitals. I think that he has done this well and fairly. I also think it is an appropriate thing to do since, after all, the vast majority of babies born in Minnesota and in the country are delivered by private practitioners in private hospitals. I would like to offer these comments.

Each month at department meetings, we review the circumstances relating to labor and delivery with regard to all babies born with depressed Apgar scores. We always find some that are unexplained. This suggests that something occurred that was missed by ordinary clinical observation, because it has been shown that if fetal heart rate patterns are normal up to within twenty or twenty-five minutes of delivery, 99% of the babies are in good condition. My conclusion on this first point is that we should, at General Hospital, be doing more monitoring than we are. Reports from elsewhere suggest that 20% to 30% of deliveries might be an optimal number depending on the frequency with which oxytocin induction and/or stimulation is used.

I think everyone agrees that in private practice, the numbers of high-risk pregnancies and the numbers of patients who require monitoring is proportionately a good deal lower than at Hennepin County General Hospital. Nevertheless, every private service has some candidates. The differences are only in percentages.

It also seems generally agreed that monitoring detects evidences of fetal distress that ordinary observation of labor and auscultation of fetal heart tones will not, and that monitoring, furthermore, can pick up signs of distress very early in the course of its development. When detected such early distress can be treated in utero by administration of oxygen to the mother, position change, discontinuance of oxytocin if it is being given, taking measures to elevate the blood pressure if there is a blood pressure drop, and if it is indicated, termination of the labor. Such early detection and early treatment minimizes the time during which the fetus is distressed. Simple logic would suggest that this has to be good.

Monitoring in other institutions has provided a substantial reduction in the numbers of cesarean sections done for fetal distress. Furthermore, it probably reduces the number that are done for certain other conditions, such as disproportion, diabetes, toxemia, abruptio, etc. As long as the fetus in these high-risk patients remains in good condition as manifested by heart rate patterns, labor or trial of labor can be allowed to proceed—often to vaginal delivery. On the other hand, if we were not so sure of the safety of the labor to the patient and fetus, we might be tempted to terminate it by cesarean section.

Finally, I agree that the costs in terms of time expended by trained people is high. A physician has to be there to do the hookup, to watch the equipment, and to interpret the tracings. Furthermore, it takes some special training to do this. All in all, I am inclined to agree that it is probably impractical to get monitoring done in most private hospitals as *obstetrics is now practiced,* and furthermore, that the expected yield would be relatively small. On the other hand, I think that monitoring is here to stay, and that more of it should be done. What then is the solution?

It may be that some redistribution of manpower is required. Perhaps obstetrics should be practiced by groups of physicians which will allow completely adequate hospital coverage and utilize paramedical personnel for many of the things that obstetricians now do in their offices. Many hospital obstetrical services that are small and inefficient should be closed. Larger concentration of patients will bring larger numbers of high-risk problems and make more feasible the provision by the hospitals of adequate services, including house staff, monitoring equipment, qualified anesthesia, newborn intensive care units, etc. Finally, I believe that where circumstances don't permit development of facilities big enough to accomplish this, that high-risk obstetric patients should be referred to a center which can provide such services.

Special Article

The Changing Face of Medicine*

RAYMOND J. JACKMAN, M.D.†

I WAS A MEMBER of this House of Delegates some 25 years ago, and I should like to share with you for a few minutes some of the changes that have taken place since that time. In the era of which I speak, the doors to deliberations of this House of Delegates, for the most part, were closed to the news media. Medicine shunned publicity with a passion.

Medicine and the Media

Then, after years of knocking on the door, Victor Cohn, a science writer for the *Minneapolis Tribune*—now with the *Washington Post*—was admitted, tentatively at first, and was soon found to be friendly to medicine. Gradually he was welcomed warmly, as were other newspapermen and writers. That was in the 1930's and 1940's, a time when personal reticence and humility in physicians were thought commendable, and anything that smacked of self-advancement was considered unethical. The public's growing interest in science and medicine, the news media's effort to meet the public interest, and the willingness of some scientists to step into the public spotlight have produced a situation which appears to be steadily worsening or bettering, depending on your point of view.

Private Practitioner and Publicity

Today it would seem that only the private practitioner is denied the doubtful privilege of self-display. There are those who say the power of fame and money is effacing the tradition of good taste which physicians had thought important but which is more often contemptuously dismissed by some of the public as "hypocrisy." They would make the physician's behavior no different from that of anyone else.

Recognition

It is true that no human trait is stronger than the desire for recognition. It is the most potent, if not the most laudable, stimulant to achievement. Like it or not, the desire for approbation is an integral part of the human scene, and no amount of mock humility will rid us of it.

As I think back about 40 years ago, when I was graduated from medical school, changes that have occurred in physicians' behavior are really incredible. When I began to practice, conformity was the order of the day; now the complete opposite is true. The public now calls medical dignity "pretension," and quarrels between two of our internationally known surgeons are front-page news, even in the conservative WALL STREET JOURNAL.

Ego has to be the central phenomenon of the Twentieth Century, even if patriotic Americans pretend it does not exist in their heroes. The most monstrous exhibition of ego in a brave man in many a year was Alan Shepard's three whacks at a golf ball while standing on the moon. There, in a space suit and hardly able to stand, he put a club head on an all-purpose tool and, restricted to swinging with one arm, he dubbed the first two shots, but on the third in a low gravitational field the ball went a half mile.

Television as a Force

Have you ever sat back and reflected on what powerful forces the news media, and particularly television, are? Big-league football games are, and even the launching of Apollo 14 was, scheduled for prime viewing time. Even the agitators hold off, if they can, to do their "thing" until the television camera is pointed at them. In your wildest dreams 20 or 30 years ago, could you picture a presumably noted surgeon performing the very experimental heart transplant before the eye of the television camera, telecast to the

*Presidential Address to the House of Delegates, Minnesota State-Medical Association, St. Paul, Minnesota, May 16, 1971.

†Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

public from coast to coast? In your wildest dreams of years ago, could you picture individual citizens with no medical or scientific background debating in news media or before Congressional committees the merits or demerits of the "pill," marijuana, and even LSD? And guess who said this, "Since the advent of heart pacemakers and catheterization, the hospital environment has become so dangerous that today it is the site of more electrical accidents than any industry except mining."

Order of the Day

Change and innovations seem to be the order of the day, as they have always been, and the public, the consumer—call him what you will—is here to stay and is very much involved in things medical. From the point of view of the public, there is nothing sacred about solo practice, and there is nothing unethical about having a physician accept a yearly salary from a third party, be it an insurance company or the federal government, rather than a fee for service.

Rising Costs

The rising costs and unsatisfactory state of medical care have finally gotten just about everyone impatient to see a change, and at present there are at least eight bills affecting the nation's medical care being debated by our national legislators. Both major parties are participating in one way or another. Some of the plans, like Senator Kennedy's, are visionary and extreme; some, like the President's and the American Medical Association's Medicredit, are more conservative. But you should be prepared —like it or not, deep change is coming.

Malpractice Dilemma

The major questions which physicians must help the public answer are those related to how people can obtain the best health care at costs that can be borne. But since the consumer has entered into systems of health-care delivery, he also should be brought face to face with vexatious problems such as the "malpractice dilemma."

The rapid increase in money awards against physicians arises from the fact that many suing patients and many jurors entertain the opinion that physicians make too much money from their practice. The threat of malpractice litigation dramatically affects the practice of medicine. Physicians indeed, and for good cause, are becoming supercautious in an effort to protect themselves. They are practicing defensive medicine. They have been forced into a position which compels them to order extra tests and xrays so that the record will show that their ministrations were conscientious; they keep patients in hospitals longer to ensure that treatment will be considered adequate, and they avoid risky diagnostic procedures and ignore new treatment techniques for fear of accusations of resort to unnecessary methods.

Costs of Liability

Physicians have to pass on the high costs of liability to their patients. If the patient-consumer is going to involve himself in things medical, medicolegal disputation is one area in which he should be encouraged to enter.

For instance, the contingency fee has paved the way for the great acceleration in allegations of negligence. In case you do not know what the contingency fee is, let me say that it is an agreement between the attorney and his client—the plaintiff—in which the attorney agrees to accept a percentage of the damages (money), if such are awarded, as his legal fee. In many instances the attorney's share is 70%, whereas the damaged plaintiff receives but 30%. This type of fee system, we might observe, is not so much the poor man's key to the courthouse as it is the lawyer's key to the bank.

Moreover, this particular arrangement, in respect to the source of the legal fee, is illegal in every country except the United States. Our leaders in Washington blandly discuss their multibillion-dollar projects for improving the nation's health and just as blandly ignore this vicious and immoral contingency-fee system as it operates to the detriment of good medical practice. I think it should be abolished, made illegal, and I think our concerned consumers should be asked to participate to the extent of helping to formulate legislation to outlaw the contingency fee, because in the long run the consumer-patient has to pay for the physician's high premium for malpractice insurance.

Feelings on Fees

I also feel that physicians should have an advance understanding with their patients as to

what fee will be charged and what it will cover and not cover. I also feel that physicians should use discretion in efforts to collect from slow-paying or dissatisfied customers. That is, I think practitioners should exercise prudence before they turn over unpaid accounts to collection agencies or to attorneys for collection. Most collcetion agencies use the contingency-fee system, meaning that they take a percentage of the monies collected as their pay, and as a result they do much coercion and resort to threats to collcet a bill. This sort of thing alienates the patient, who spreads his complaints by word of mouth, and often such a situation is the spark that starts a malpractice suit.

Professional Liability

At present the American Medical Association is in the process of developing a professional liability program in cooperation with the state medical societies and various insurance carriers. Concurrently, the American Medical Association is developing a data center to provide a single repository of informational profiles useful in identifying incidents and causes of liability claims.

Both of these sound like laudable projects.

Medical-Social Evolution

On the brighter side, some things have happened in the past year in the medical-social evolution which deserve comment.

Student Activism

I, for one, am delighted with medical-student activism in organized medicine. I hope it continues and expands, but many of the activists, unfortunately, even as their elders, feel too harassed by other demands on their time to enter into productive participation. Youth tends to have a glorious idealism and confidence that it can put the world right, blissfully unaware that most preceding generations were imbued with similar feelings. Youth is thus inclined to feel that imperfection is caused by the "establishment" rather than that it persists despite efforts of the "establishment" to correct its failings.

Group Practice

I feel very strongly that the increasing tendency toward group practice is all for the good in providing medical care to needy areas. I am not advocating a Kaiser Permanente plan, although it might be good for some areas; on the contrary, freedom of choice of medical group or physician is important and any plan for prepaid care should be evolutionary rather than revolutionary. Fifty-two percent of Minnesota practicing physicians in 1969 belonged to a group of three or more practitioners compared to 41% in 1967. The national average in 1967 was 14%. Parallel to this same vein of thought, I feel that many small towns crying for a physician really do not need one. Transportation, even in respect to vital services, is far different from that of 25 or 30 years ago, when a village medical practice was relatively static because of the imposition of natural physical impediments.

Public Duty

I believe that the Emergency Health Personnel Act, signed into law in 1970, allows Public Health Service physicians, in lieu of the customary two years of military duty, to dispense medical care in areas in which local officials request their presence. This program will be administered by the Department of Health, Education, and Welfare, and although it is not completely new, it will be interesting to see how it operates in some of the ghetto areas which have only one physician for every 10,000 residents.

Catastrophic Health Insurance

I think the inevitable legislation of some type of government-sponsored catastrophic health insurance, similar to that envisaged in the resolution introduced by Dr. Jack Falls and passed by this House of Delegates in 1970 is all for the good.

Women

I think the trend toward more women's and minority groups' being accepted by our medical schools is all for the good. At the end of 1970 there were 334,044 physicians in the United States, a gain of 9,102 over 1969. Of these,

278,535 were engaged in patient-care activities as compared to 261,722 the year before.

Consumer Rights

I think the notion of involving the consumer —the layman—in our Blue Cross plans to let them know why hospitals and medicine are so costly and to share the abusive brunt, is a good one. Blue Cross and other hospital insurance companies are aware of the overemphasis on payment for inpatient care which has resulted in increased use of the most expensive element of health care: the hospital. I believe the policy of Blue Shield plans for adequate public-consumer representation is commendable. In at least eight states the public in such an arrangement is represented by a majority and the physicians by a minority on the corporate body.

Monitoring

The whole area of monitoring not only the quality and quantity and the cost factors of health care—call it "peer review," "medical foundations," or what you will—is inevitably important. I think a responsible profession must take very seriously the allegations that medical care is becoming too expensive. I think we have to establish fair and reasonable fees that are consistent and comprehensive and then demand fairness and honesty on the part of participating physicians. I think I am quoting your incoming President, Bob Kelly, correctly when he said at a meeting of the Medical Services Committee "that we physicians have to set usual, customary and prevailing fees for a given period of time to satisfy the consumer and the insurance carrier." I heartily agree. Then the gougers and defrauders, and there are some, can be dealt with sternly and forcefully.

Rights, Not Privilege

I feel that health care for all is a right and not a privilege. For many of us, re-education in apposition to such newer concepts will be needed and for many the experience will be painful.

Family Physicians

The era which we are now entering, with maximal emphasis on the objective of changing the training of the traditional family physician so that a new type of highly competent, comprehensive, primary-care physician will be produced in sufficient numbers effectively to deliver health care to the American public, is interesting and challenging. But medicine as a whole should not be led by its anxieties into increasing the number of physicians by lowering the quality of their training.

Final Plea

One final plea. In the days ahead, we in organized medicine are going to have to take one of two roads. We can take a militant, strong-union, resort-to-strike plan, as practitioners did in Canada, or we can follow the more democratic plan of negotiating through our leaders with the federal government, and soliciting the understanding of the public, in the hopes of shaping our destinies into acceptable channels. I am for the latter plan.

If ever medicine needs a united front through its county, state and national organizations, it is during these next two years. Each of us must be a battler for the right.

'Tis written in the Hebrew Chronicle,
How the physicians, leaving pill and potion,
Prescribed, by way of blister, a young belle,
When old King David's blood grew dull in motion,
*And that the medicine answer'd very well.**

*Lord Byron: Don Juan, Canto I, Verse CLXVIII 1819.

Classified Advertisements

Classified advertising rates are thirty (30) cents a word; minimum monthly charge $7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

PHYSICAL MEDICINE AND REHABILITATION —Three year approved residency in a University Hospital. Comprehensive rehabilitation for adults and children including outpatient, inpatient, consultation, diagnostic and special services and clinics. Electrodiagnostic, cardiovascular, kinesiologic and myopathologic diagnostic and research laboratories. Training program supervised by 7 full-time physiatrists. Internship requirements may be incorporated into residency program to meet Board requirements for eligibility three years after graduation from medical school. Master and doctorate degrees offered in Graduate School program for physiatrists interested in academic careers. For further details contact Frederic J. Kottke, M.D., Professor and Head, Department of Physicial Medicine and Rehabilitation, University of Minnesota, 860 University Hospitals, Minneapolis, Minnesota 55455.

GENERAL PRACTITIONER to join 2 man group, family practice. Busy, well established location in town of 2000 with drawing area 10,000. Excellent schools, churches, golf club, hunting and fishing, 65 miles from Twin Cities. Completely equipped and staffed clinic. New 40-bed hospital, accredited. Salary arrangements to start and early partnership. Write MINNESOTA MEDICINE, Box 465, 375 Jackson St., St. Paul 55101.

WANTED: General practitioner wanted to join a young four man group in a fast growing area just 30 minutes south of the Twin Cities. You will practice in a new clinic, hospital and nursing home. A compete resume of facilities, practice and area is available. Contact M. H. Hunter, M.D.; Rivers Edge Medical Clinic, Farmington, Minnesota. Telephone 463-7181.

GENERAL SURGEON NEEDED for well established group of 7 g.p.'s. Located in beautiful northern Minnesota community serving 15,000 people. Stable diversified economy, excellent medical facilities, year round recreation and cultural center, and extremely pleasant family environment. Starting salary open depending on training and experience, all fringes, IRS approved pension fund, and attractive buy in option after 1 year. Contact. K. H. Stolen M.D. or T. R. Brill Adm. Box L Grand Rapids, Minn. 55744 or call 218-326-6613.

AVAILABLE—Young married G.P. with some surgical experience. Deferment not needed. Write Minnesota Medicine, 462, 375 Jackson St., St. Paul 55101.

INTERNIST WANTED—Thirty-five doctor prepaid multi-specialty group is opening attractive new offices. Excellent earnings and assured advancement in desirable professional environment. Many tax sheltered benefits, good community near downtown. Generous vacation, conference and teaching time. A. F. Andergg, M.D., Group Health Plan, Inc., 2500 Como Ave., St. Paul, Minn. 55108. Phone (612) 645-5851.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul 55101.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

GENERAL PRACTITIONER to join young 5 man family practice group. College town of 7,000 serving approximately 20,000 population. Accredited hospital with specialist consulting staff. 30 miles from St. Paul-Minneapolis, Minnesota. Contact R. M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin 54022. Phone (715) 425-5322.

GENERAL PRACTITIONER needed for an extremely busy rural practice in Northern Minnesota. Excellent hospital and clinic facilities. Starting salary of $25,000.00 with possible early partnership. Write MINNESOTA MEDICINE, Box 466, 375 Jackson, St. Paul, Minn.

FAMILY PHYSICIAN WANTED to take over busy well established practice in Lake Calhoun area. Fully equipped office with 100 MA x-ray, lab. and operating rooms. This is an especially good opportunity for one or two Physicians. Will introduce clientel. We also service many Nursing Home Patients. John J. Pone, M.D. 1620 West 32nd Street, Minneapolis, Minnesota 55408. Phone: 825-0400.

Continued on page 490

T_4 IS THE PREDICTABLE HORMONE BECAUSE IT LOVES PROTEIN.

SYNTHROID® (sodium levothyroxine) is pure synthetic T_4, the major circulating thyroid hormone. It is reliable to use because of its affinity for protein-binding sites in the blood. T_3 is more fickle. Sometimes it binds. Sometimes it doesn't. T_4 more *predictably* binds to protein.

ALL THYROID-FUNCTION TESTS ARE USEFUL IN MONITORING SYNTHROID THERAPY

No calculations are needed, test interpretation is simple.

Any of the commonly used T_4 thyroid function tests (P.B.I., T_4 By Column, Murphy-Pattee, Free Thyroxine) are useful in monitoring patients on T_4 because they *all* measure T_4. Patients on SYNTHROID are thereby easy to monitor because their results will fall within predictable, elevated test ranges. Of course, clinical assessment is the best criterion of the thyroid status of the drug-treated patient.

TEST	HYPOTHYROID	SYNTHROID THERAPEUTIC NORMAL
P.B.I.	Less than 4 mcg %	6-10 mcg %
T_4 By Column	Less than 3 mcg %	7-9 mcg %
T_3 (Resin)	Less than 25%	27-35%
T_3 (Red Cell)	Less than 11%	11.5-18%
Free Thyroxine	Less than 0.7 nanograms %	0.7-2.5 nanograms %
Murphy-Pattee	Less than 2.9 mcg %	4-11 mcg %

TWO GOOD REASONS WHY THE ROAD TO NORMALIZED THYROID STATUS IS SO SMOOTH FOR THE SYNTHROID PATIENT

(1) The onset of action of T_4 is gradual. It has a long in vivo "half-life" of over six days. (Occasional missed doses or accidental double-doses are of le concern because of this factor)' (2) since SYNTHROID contains o T_4, the potential for metabolic surges traceable to more potent iodides (T_3) is eliminated.

AS WITH ANY THYROID PREPARATION, CAUTIOUS OBSERVATION OF THI PATIENT DURING THI BEGINNING OF THERAPY WILL ALER THE PHYSICIAN TO ANY UNTOWARD EFFECTS.

Side effects, when they do occu are related to excessive dosage Caution should be exercised in administering the drug to patien with cardiovascular disease. Re the accompanying prescribing information for additional data write Flint Laboratories.

Choose the Smooth Road ...to thyroid replacement therapy

ATIENTS CAN BE UCCESSFULLY AINTAINED ON A RUG CONTAINING HYROXINE ALONE.

yroxine (T_4) is, as you know, e major circulating hormone oduced by the thyroid gland. is also produced, in smaller ounts, and is active at the llular level. For years it has been vorking hypothesis among docrinologists that T_4 is nverted by the body to T_3. In 70 this process, called eiodination," was demonstrated Braverman, Ingbar, and Sterling[2]. does convert to T_3, though the ecise quantities are still being idied.

The conversion has been nically demonstrated during the ministration of T_4 to athyrotic tients. Their thyroid status is rmalized on SYNTHROID alone, the presence of T_3 in these tients has been clearly shown.

WHY DOES SYNTHROID COST LESS THAN SYNTHETIC DRUGS CONTAINING T_3?

Very simple. T_3 costs more to make synthetically than does T_4. So it is economically necessary for a synthetic thyroid medication containing T_3 to cost more than one containing T_4 alone. Synthetic combinations cost patients nearly 50% more than SYNTHROID[3] because the T_3 costs more to start with; also there is the additional expense of formulating a tablet containing two active ingredients.

Synthroid®
(sodium levothyroxine)

HE FACTS ARE LEAR AND HERE OUR OFFER.

CTS:
nthetic thyroid drugs are an provement over animal gland ducts. Patients, even athyrotic es, can be completely intained on SYNTHROID (T_4) one. Thyroid function tests are sy to interpret since they are *dictably* elevated when the tient adheres to SYNTHROID. all synthetic thyroid drugs, NTHROID is the most onomical to the patient.

A

OFFER:
Free TAB-MINDER medication dispensers to start or convert all your hypothyroid patients to SYNTHROID. Free information to physicians on role of thyroid function tests in a new booklet titled: "Guideposts to Thyroid Therapy." Ask us.

Name

Address

City State Zip

Indications: SYNTHROID (sodium levothyroxine) is specific replacement therapy for diminished or absent thyroid function resulting from primary or secondary atrophy of the gland, congenital defect, surgery, excessive radiation, or antithyroid drugs. Indications for SYNTHROID (sodium levothyroxine) **Tablets** include myxedema, hypothyroidism without myxedema, hypothyroidism in pregnancy, pediatric and geriatric hypothyroidism, hypopituitary hypothyroidism, simple (nontoxic) goiter, and reproductive disorders associated with hypothyroidism. SYNTHROID (sodium levothyroxine) **for Injection** is indicated for intravenous use in myxedematous coma and other thyroid dysfunctions where rapid replacement of the hormone is required. The injection is also indicated for intramuscular use in cases where the oral route is suspect or contraindicated due to existing conditions or to absorption defects, and when a rapid onset of effect is not desired.

Precautions: As with other thyroid preparations, an overdosage may cause diarrhea or cramps, nervousness, tremors, tachycardia, vomiting and continued weight loss. These effects may begin after four or five days or may not become apparent for one to three weeks. Patients receiving the drug should be observed closely for signs of thyrotoxicosis. If indications of overdosage appear, discontinue medication for 2-6 days, then resume at a lower dosage level. In patients with diabetes mellitus, careful observations should be made for changes in insulin or other antidiabetic drug dosage requirements. If hypothyroidism is accompanied by adrenal insufficiency, as Addison's Disease (chronic subcortical insufficiency), Simmonds's Disease (panhypopituitarism) or Cushing's syndrome (hyperadrenalism), these dysfunctions must be corrected prior to and during SYNTHROID (sodium levothyroxine) administration. The drug should be administered with caution to patients with cardiovascular disease; development of chest pains or other aggravations of cardiovascular disease requires a reduction in dosage.

Contraindications: Thyrotoxicosis, acute myocardial infarction. **Side effects:** The effects of SYNTHROID (sodium levothyroxine) therapy are slow in being manifested. Side effects, when they do occur, are secondary to increased rates of body metabolism; sweating, heart palpitations with or without pain, leg cramps, and weight loss. Diarrhea, vomiting, and nervousness have also been observed. Myxedematous patients with heart disease have died from abrupt increases in dosage of thyroid drugs. Careful observation of the patient during the beginning of any thyroid therapy will alert the physician to any untoward effects.

In most cases with side effects, a reduction of dosage followed by a more gradual adjustment upward will result in a more accurate indication of the patient's dosage requirements without the appearance of side effects.

Dosage and Administration: The activity of a 0.1 mg. SYNTHROID (sodium levothyroxine) **TABLET** is equivalent to approximately one grain thyroid, U.S.P. Administer SYNTHROID tablets as a single daily dose, preferably after breakfast. In hypothyroidism without myxedema, the usual initial adult dose is 0.1 mg. daily, and may be increased by 0.1 mg. every 30 days until proper metabolic balance is attained. Clinical evaluation should be made monthly and PBI measurements about every 90 days. Final maintenance dosage will usually range from 0.2-0.4 mg. daily. In adult myxedema, starting dose should be 0.025 mg. daily. The dose may be increased to 0.05 mg. after two weeks and to 0.1 mg. at the end of a second two weeks. The daily dose may be further increased at two-month intervals by 0.1 mg. until the optimum maintenance dose is reached (0.1-1.0 mg. daily).

Supplied: Tablets: 0.025 mg., 0.05 mg., 0.1 mg., 0.15 mg., 0.2 mg., 0.3 mg., 0.5 mg., scored and color-coded, in bottles of 100, 500, and 1000. Injection: 500 mcg. lyophilized active ingredient and 10 mg. of Mannitol, N.F., in 10 ml. single-dose vial, with 5 ml. vial of Sodium Chloride Injection, U.S.P., as a diluent. SYNTHROID (sodium levothyroxine) for Injection may be administered intravenously utilizing 200-400 mcg. of a solution containing 100 mcg. per ml. If significant improvement is not shown the following day, a repeat injection of 100-200 mcg. may be given.

UNIQUE CHALLENGE—THE FAMILY PRACTICE DEPARTMENT of St. Paul-Ramsey Hospital needs an experienced general practitioner. If you want to promote the concepts of general practice and participate actively in the Family Medicine movement, this is for you. This program enjoys the cooperation of all 19 departments at St. Paul-Ramsey and its 50 full-time specialists. It has solid funding and represents a unique blend of patient-oriented care, university academic affiliation and social involvement. For further details regarding academic appointments, salaries and fringe benefits, please contact Vincent R. Hunt, M.D., Director, Department of Family Medicine and Community Health, St. Raul-Ramsey Hospital, St. Paul, Minnesota 55101. Telephone: (612) 222-4260, Ext. 616.

FAMILY PRACTITIONER for an eight man Family Practice group. High earning potential, young active group, expanding into "New Town" suburban community. Opportunity to teach students and Family Practice residents. Robert E. Bundt, M.D., 3809-42nd Avenue South, Minneapolis, Minnesota 55406 (612) 721-6261.

EAST SIDE-ST. PAUL: Doctor's suite available July 1, 1972. Reception room, private office, laboratory, three examining rooms, storage and good parking space. Present Doctor occupant entering teaching field. For information, contact R. H. Rockholt, 1489 Clayridge Avenue, St. Paul, Minn. 55119; Phone (612) 777-7248.

WANTED: Internist or General Practitioner to join Incorporated 5 man group of 4 GPS, and a General Surgeon. 65 bed hospital with ICCU located 65 miles north of Mpls. Good recreational facilities available. For further information contact L. J. Brettingen, M.D. (612) 679-1313.

STUDENT HEALTH PERSONNEL WANTED: Medical Director of Student Health Service, Bemidji State College, Bemidji, Minnesota, 56601. Responsible for programs and health care for 4,700 students. Position available July 1, 1972, or earlier. Contact Dr. C. J. Kemper, Vice President for Student Affairs, Bemidji State College, Bemidji, Minnesota, 56601. Phone: (218) 755-2019.

TWO VACANCIES IN JUNE: Psychiatrist and Internist or General Medicine. Active outpatient clinic, Winston-Salem. Normally 40-hour workweek. Excellent facilities, retirement and insurance plans; liberal vacation and sick leave benefits. Can pay moving expenses. Salary range $23,424-$29,-848. Any state or DC license required. Equal opp. employer. Write Chief of Staff, VA Hospital, Salisbury, N.C. 28144.

HIGHLAND PARK OFFICE SPACE at $6.00 per square foot. All utilities furnished. Zoned heating and air conditioning, carpeted. New Highland Professional Bldg. 621 So. Cleveland Avenue, St. Paul. Dr. Jack Shepard 699-1709.

PSYCHIARIST-CHALLENGING OPPORTUNITY TO practice progressive and innovative treatment to wide variety of mental disorders; excellent facilities and ancillary staff; comfort of small town living with nearby city conveniences; excellent school system; good climate; regular hours, 30-day vacation, exc. retirement, life, health ins. plans; can pay moving expenses; salary range $23,424-$29,848; any state or DC license required; equal opp. employer. Write Chief of Staff, VA Hospital, Salisbury, N.C. 28144.

SPOONER-WASHBURN COUNTY: Needs a surgeon. An opportunity to live in one of the more beautiful spots in the country surrounded by wilderness areas with unending lakes and streams. A fine school system away from urban crises, and still within easy driving distance from St. Paul-Minneapolis. A rewarding varied medical experience financially competitive with any other area. Contact Rudy Matzke, M.D., Spooner Clinic Ltd, Spooner, Wisconsin 54801. Phone (715) 635-2151.

GENERAL PRACTITIONER: County seat community of 2000. Modern 35 bed hospital 4 blocks from fully equipped clinic. Present associate retiring January 1, 1973. Early partnership. Contact H. A. Knoche, M.D., Gaylord, Minnesota 55334. Telephone 612-237-2528.

Minnesota State Medical Association

It's All Set for You in '72

119th Annual Meeting

Mini-scientific sessions, maxi-scientific sessions, exhibits, luncheons, banquets, House of Delegates and reference committee meetings are some of the events which promise to insure that the 119th Annual Meeting of the MSMA, May 18 through 20, in Rochester will remain true to its reputation as the Upper Midwest's Great Medical Meeting.

A unique feature will be an open hearing for physicians conducted by the American Medical Association in conjunction with this year's Annual Meeting.

The AMA Council on Long Range Planning and Development has selected Minnesota as one of only two states for these hearings to be held prior to comparable hearings planned for the AMA's Annual Convention June 18-22 in San Francisco.

The Minnesota hearings will be divided into two sessions, the first to be held from 2 to 5 P.M. on Thursday, May 18, and from 9 to 12 Noon on Friday, May 19. The purpose will be to give physicians in the area an opportunity to speak their minds on AMA policies and procedures. Following are the general subjects chosen for discussion: 1. Proposed changes in the AMA constitution and By-laws, 2. Organization structure, and 3. Delineation of committee responsibilities. Physicians who wish to appear as witnesses have been previously requested to submit their statements to the AMA by May 5.

University of Minnesota president Doctor Malcolm Moos will be the Thursday Annual Meeting luncheon speaker. The Friday luncheon speaker will be Doctor Charles C. Edwards, Commissioner of the Food and Drug Administration, Department of Health, Education and Welfare.

Included in the schedule of afternoon "in depth" maxi-sessions on Thursday will be a double session (2:00-5:00 P.M.) titled "Recognition and Management of the Dependent Person," sponsored by the Committee on Mental Health, Subcommittee on Alcoholism and Drug Abuse. The MSMA Committee on Environmental Health will also sponsor a two part session on Friday (2:00-5.00 P.M.) titled "Patient Care and Pollution Problems." This symposium is open to physicians, nurses and hospital administrators.

Seven of this year's scientific sessions have been arranged by the Minnesota Chapter of the American College of Surgeons.

Physicians attending the Annual Meeting will have the opportunity to "meet your medical school deans" at one of the Thursday afternoon sessions. Present will be associate deans from the University of Minnesota Medical School, the Mayo Graduate Medical School and the dean of the new U of Minnesota Medical School, Duluth.

A detailed schedule of additional scientific sessions follows this Annual Meeting preview.

Tee-off time for the annual Physicians' Golf Tournament is Wednesday, May 17, 2:00 P.M. at the Rochester Golf and Country Club. Prior to the tournament a 12:30 P.M. stag luncheon will be served. The registration fee of $10.00 includes luncheon and tournament green fees.

Tennis tournament—Men's Singles Wednesday, May 17, 2:00 P.M., at the Rochester Tennis Club. Entry Fee, $3.00—pre-registration requested. Payment at the Tennis Club. Doubles upon request. Contact: Dr. Clark Millikan, Mayo Clinic.

The Annual Banquet is scheduled for Thursday, May 18, 7:00 P.M. It will be preceded by the President's Reception at 6:00 P.M.

The House of Delegates will convene for its opening session Wednesday, May 17, 1:00 P.M., and reference committees will meet at 4:00 P.M. and 7:30 P.M. following the close of the first session of the House. The second session of the House of Delegates will meet Friday at 2:00 P.M.

The Committee on Scientific Assembly is pleased to announce the following special events scheduled by specialty societies in conjunction with the Annual Meeting:

The Minnesota Physiatric Society will hold a dinner meeting Friday, May 19.

The Minnesota Chapter of the American College of Surgeons will hold a luncheon on Friday, May 19, 12:15 with a business meeting following.

The Minnesota Academy of Ophthalmology and Otolaryngology will hold a cocktail hour and dinner Friday, 6:30 P.M., Council Meeting preceding at 5:00 P.M.

A spring all-day meeting of the Minnesota Society of Clinical Pathologists, beginning at 9:00 A.M., Saturday, May 20.

A luncheon meeting, Minnesota Chapter of the Flying Physicians Association Saturday, May 20, 12:00. Interested physicians are urged to contact Alex Webb, Jr. M.D., 311 Terminal Bldg., Minneapolis-St. Paul International Airport, Mpls. or Frank J. Bonello, M.D., 1074 So. Robert St., West St. Paul.

Physicians are encouraged to save time by preregistering. Pre-registration materials are enclosed with all Annual Meeting mailings.

Mini and Maxi-Scientific Sessions held in Mayo Civic Auditorium and Art Center.

Meeting

Northlands Regional Chapter of the American College of Chest Physicians

The annual meeting of the society is planned for May 6th, 1972, at Mann Hall, Medical Science Building, Mayo Clinic, Rochester, Minnesota.

Theme of the morning meeting will be "Chronic Obstructive Lung Disease" and of the afternoon meeting "Coronary Artery Disease."

Help put our best natural resources to work.

As you know, today there is a crying need for technicians.

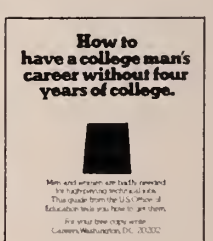
The trouble is many bright kids don't know about these jobs.

So the U.S. Office of Education, The Conference Board and The Advertising Council have put together a full-scale advertising program to get the message through.

It consists of two parts. One is a seven page booklet giving all the facts on technical careers, technical schools and financial aid. The other is a poster offering the booklet.

You can help by handing out the free booklet—and seeing that the poster is displayed in high schools, churches, youth clubs, wherever young people hang out.

For free samples of our booklet and poster and information on quantity reprints, use the coupon at right.



Reprints are cheap. Only $4.00 per hundred for the poster. $5.00 per hundred for the booklet.

For a small additional charge, we'll even imprint your company's name.

Mail the coupon. You'll be helping kids who want to make something of themselves—and assuring yourself a supply of technicians for the future.

In Memoriam

I have trodden the winepress alone.—Isaiah. LXIII. 3

ROY A. LUNDBLAD, M.D.

Dr. Roy A. Lundblad, 66, died March 30 in Oceanside, California. A 1929 graduate of the University of Minnesota Medical School, he had been in practice for 37 years until his retirement in 1966. He was named chief of staff at Swedish Hospital, now Metropolitan Medical Center, in 1957, and had served in the Army Medical Corps. in World War II.

Dr. Lundblad was a member of the Hennepin County Medical Society and the American Medical Association, and an Associate Member of the Minnesota State Medical Association.

He is survived by his wife, Evelyn, a son, Rodger, and a daughter, Karen.

GEORGE A. EARL, M.D.

Dr. George A. Earl, 87, surgeon, died March 17. Dr. Earl served as President of the Minnesota State Medical Association in 1939, was a Council member from the Fifth District from 1933 to 1938, and for the years 1935 to 1938, served as Chairman. He also was a long-time Chairman of the Committee on Medical Economics which formerly served as a connecting link for many important economic and social committees of the State Association.

In addition, Dr. Earl was one of the organizers of the Medical Alumni Association of the University of Minnesota, served as secretary of the Mayo Memorial Medical Commission for the erection of the Mayo Medical Building on the University campus, and was a co-founder of the Association of Baptist Homes and Hospitals. He was also a member of the American Medical Association and Ramsey County Medical Society and a Life Member of the Minnesota State Medical Association.

He is survived by his son, Roland, and a daughter; Mrs. Edward P. Davis.

OSCAR J. ENGSTRAND, M.D.

Dr. Oscar J. Engstrand, 76, Minneapolis surgeon for 50 years, died January 14, after a long illness. He had an office in the Physicians and Surgeons Building up to five years ago and had been on the Swedish Hospital staff for 40 years.

He was born in Dawson, Minnesota, and was a member of the Hennepin County Medical Society and the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

Dr. Engstrand is survived by his wife, Florence, and three daughters, Elizabeth, Audrey and Jacquelyn.

THOMAS M. GRIFFIN, M.D.

Dr. Thomas M. Griffin, 41, anesthesiologist at St. Lukes Hospital, St. Paul, died March 24. He was born in Kildysart, County Clare, Ireland, and had lived in Mendota Heights for 12 years.

He was a member of the American Medical Association, Ramsey County Medical Society, the Minnesota State Medical Association, the American Society of Anesthesiologists, a graduate of the Royal College of Surgeons and Physicians of Dublin and had done postgraduate work at the University of Minnesota.

He is survived by his wife, Irene, a daughter, Patricia, and four sons, Thomas, Brian, Cathal and Colm.

ROBERT L. WILDER, M.D.

Dr. Robert L. Wilder, 71, a longtime Minneapolis pediatrician, died February 25, in San Miguel, Mexico.

A University of Minnesota graduate, Dr. Wilder practiced medicine from 1926 until 1957, when he retired. He was an associate clinical professor of pediatrics at the University and in 1947 was chief of staff at Abbott Hospital. Dr. Wilder was a member of the Hennepin County Medical Society, the American Medical Association, a Fellow of the American Academy of Pediatrics, a member of the American Forestry Association, the American Physicians Art Association, the Minnesota Society of Sculptors and an Associate Member of the Minnesota State Medical Association.

The March issue of MINNESOTA MEDICINE carries one of Dr. Wilder's paintings "Mexican Pilgrimage."

Dr. Wilder is survived by his wife, Alfreda, sons, Dr. Walter L. Wilder of Minneapolis, and John, and a daughter, Martha.

VICTOR H. GARDNER, M.D.

Dr. Victor H. Gardner, 78, founder of the Fairmont Community Hospital, Fairmont, died March 9. A graduate of Leander Clark College, Iowa City, Iowa, Dr. Gardner received his medical degree from the University of Iowa Medical School. He interned in obstetrics and gynecology at the University of Iowa Hospital and practiced in Estherville, Iowa, before moving to Fairmont.

He was a member of the Blue Earth Valley Medical Society, the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

A MINNPAC INVITATION

The MINNESOTA MEDICAL POLITICAL ACTION COMMITTEE invites you to support the singularly most effective means available to make medicine's voice heard in the political arena—MINNPAC/AMPAC.

Join MINNPAC today. Participate in the political and governmental process which will ultimately determine how the practice of medicine will be structured during this decade. Your $25.00 includes both MINNPAC and AMPAC dues and will be used to assist in electing responsible men and women in both parties to the State Legislature and to Congress. The MINNPAC Board of Directors is charged with the responsibility of urging physicians and their wives to become actively involved in the support of candidates and the party of their choice. *YOUR* help is needed *NOW!* Complete the application form or merely send your $25.00 check to: MINNPAC, Metro Medical Building, 825 South 8th Street, Room 503, Minneapolis 55404.
P.S. Those of you who have already sent your check—*Thank You!*

☐ Please bill me $25.00 for my annual membership in MINNPAC and AMPAC.
☐ Membership contribution is enclosed.

Should nongovernment scientists and physicians play a role in drug regulation?

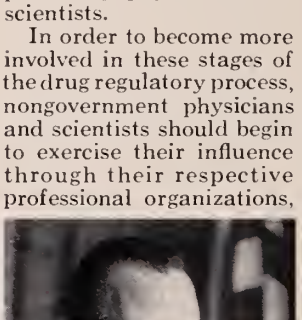
Doctor of Medicine



Herbert L. Ley, Jr., M.D., M.P.H., Formerly Commissioner, F.D.A. (1968-1969)
Currently Medical Consultant

In order for drug regulation to be effective, participation in the regulatory process from nongovernment physicians and scientists must be encouraged. Without such involvement, there will continue to be a high degree of controversy surrounding any regulations promulgated by the Food and Drug Administration.

There are two areas in which participation and communication by nongovernment physicians and scientists could significantly improve the process of regulation. First, scientists and physicians throughout the country could become involved in consulting relationships with the Food and Drug Administration in important scientific areas while regulatory policies are being evolved. If nongovernment professionals could bring their expertise and experience to bear early in the decision-making process, they would have less reason to criticize the final outcome.

Secondly, practicing physicians, academic physicians, and academic-based scientists could make it their business to comment on proposed regulations appearing in the Federal Register. Ideally, a system could be instituted whereby medical, scientific and technical people could see the Federal Register regularly, and provide the Food and Drug Administration with a body of opinion that has so far gone unheard. The FDA is caught among pressures from industry, Congress, the Presidential Administration and consumers. It should also feel pressures from practicing physicians and scientists.

In order to become more involved in these stages of the drug regulatory process, nongovernment physicians and scientists should begin to exercise their influence through their respective professional organizations,

state and national medical societies, and specialty groups. Logically, a letter from these organizations representing a collective opinion has far greater weight in the regulatory process than individual letters. If the Food and Drug Administration receives opinions from these organizations early, before a regulation gets into the Federal Register, they are in a good position to respond with further study and review. Without such dissenting opinions, there is very little incentive to make changes in proposed regulations.

One instance in which practitioners did influence drug regulatory affairs in this way is the recent controversy that arose over the legitimacy of drug combinations. The strong opinion of practitioners on the value of such medication in clinical practice played a very prominent role in making the Food and Drug Administration modify its rather restrictive policy.

Another way in which practitioners can effectively influence drug regulations is by working with drug manufacturers conducting clinical trials of chemotherapeutic agents. When a drug is rated other than effective it may only mean that there is a lack of controlled clinical evidence as to efficacy. Thus, physicians might offer to conduct clinical studies that could help keep a truly effective drug in the marketplace. The treatment of diseases such as diabetes and angina are areas where the practitioner can aid in clinical studies because patients suffering from these diseases are rarely found in the conventional hospital setting.

By working with ethically and scientifically sound study designs in his everyday practice, the practitioner could begin to play an important part in determining official ratings on drug efficacy.

Nongovernment physicians and scientists and the FDA should also improve their lines of communication to the puhlic. The medical community must develop a voice every bit as loud as that of the consumerists, the press, and others who sometimes criticize without complete information. If not, much of wha the medical community *and* federal regulators d will often be represented i simplistic and somewha misleading terms.

One illustration of th misuse of the media in thi regard is the recall of anti coagulant drugs severa years ago. This FDA actio was given publicity by th press and television tha went far beyond its prob able importance. The resul was a very uncomfortabl situation for the practi tioner who had patient taking these medications Since the practitioner an pharmacist had not bee informed of the action b the time it was publicized in most states they wer deluged with calls fron worried patients.

The practitioner can at tempt to solve these prob lems of inadequate commu nication in several ways One would be the creatio of a communications lin in state pharmacy societies When drug regulation new is to be announced, the so ciety could immediatel distribute a message to ev ery pharmacist in the stat The pharmacist, in turn could notify the physician in his local community s that he and the physicia could be prepared to an swer inquiries from pa tients. Another approac would be to use profes sional publications th practitioner receives.

All of this leads back t my opening contention: drug regulation is to be effective, timely, and relate to the realities of clinic practice, a better method communication and fee back must be developed b tween the nongovernmen tal medical and scientif communities and the regu latory agency.

ue

Maker of Medicine

Henry W. Gadsden, hairman & Chief Executive Officer, Merck & Co., Inc.

In my opinion, it is the sponsibility of all physi- ans and medical scientists take whatever steps they ink are desirable in a law- nd regulation-making ocess that can have far- eaching impact on the actice of medicine. Yet any events in the recent ast indicate that this is t happening. For exam- le, it is apparent from ug efficacy studies that e NAS/NRC panels gave ttle consideration to the idence that could have en provided by practic- g physicians.

There are several current velopments that should crease the concern of acticing physicians about ug regulatory affairs. One the proliferation of mal- actice claims and litiga- on. Another is the effort government to establish e relative efficacy of ugs. This implies that if physician prescribes a ug other than the "estab- shed" drug of choice, he ay be accused of practic- g something less than rst-class medicine. It ould come perilously ose to federal direction of ow medicine should be acticed.

In order to minimize this ind of arbitrary federal ction, a way must be und to give practitioners oth voice and represen- tation in government affairs. Government must be caused to recognize the essentiality of seeking their views. One of the difficulties today, however, is that there is no way for concerned practitioners to participate in the early stages of decision-making processes. They usually don't hear about regulations until a proposal appears in the Federal Register, if then. By that time a lot of concrete has been poured, and a lot of boots are in the concrete.

Physicians in private practice, and particularly clinicians, should press for representation on the advisory committees of the Food and Drug Administration, joining with academic and teaching hospital physicians and scientists who are already serving. Though practitioners may not have access to all available information, the value of their clinical experience should be recognized. Clinicians, for example, rightly remind us that difficulty in *proving* precise effects does not necessarily mean a drug is ineffective.

Unless practitioners are more involved in drug regulations, it will be increasingly difficult for the pharmaceutical industry and scientists elsewhere to make optimal progress in drug development. The benefit/risk ratio must be re-emphasized, and as part of this it must be acknowledged that benefit can come from the judgments of medical science as a whole. Even this concept, unfortunately, is not always accepted in drug regulatory processes. For example, if current medical opinion holds that an excess of total lipids and cholesterol in the blood is probably predisposing to atherosclerosis, and if a drug is discovered which reduces total lipids and cholesterol, the drug ought to be accepted *prima facie* as a contribution to medical science . . . until someone disproves the theory. The sponsor should not have to prove the theory as well as to develop and test the drug.

I feel a major new effort must also be made to erase the feeling of mistrust of medicine and of medicines that seems to be growing in the public consciousness. Triggered primarily by strident announcements in Washington, people are reading and hearing confidence-shaking things almost continuously. Although challenge and awareness are essential to medical advancement, our long-term goal is constructively to build, not destroy. This means strengthening patient-physician relationships based on mutual confidence and trust. And in matters of health policy, it means working toward participatory rather than adversary proceedings—where everyone with an interest and a capacity to contribute has an opportunity to be heard . . . and, if that opportunity is not spontaneously afforded him, he may seek it.

Opinion & Dialogue

What is your opinion, doctor?
We would welcome your comments.

Letters to the Editor

Dear Editor:

The history of the development of the metric system around the world is probably of little interest to the average citizen of the U.S. However, the fact that our country will soon be one of only nine nations not using the metric system, should be of great concern to each citizen of the United States.

On July 31, 1971, the Secretary of Commerce presented to the Congress a report titled: "A Metric America—A Decision Whose Time Has Come." This report urges that the country begin a 10 year program to convert completely to the metric system. In 1878 the AMA recommended the use of the metric system in medical practice and research. On November 1, 1971, the *Journal* of the AMA announced that the modified metric system known as SI (System Internationale d'Unites) would be used exclusively in that journal beginning in 1973.

The change to metric will not be painless and will not be accomplished without involving each person in the United States. We in the medical profession, use to the convenience and symplicity of the metric system, and largely converted to metric in our professional lives, can help to make this inevitable change less troublesome.

As a start in making this change, I urge the editorial board to set a date for completion of the change to metric for all medical and scientific measurements published in MINNESOTA MEDICINE. This does not involve much more than height, weight, and body temperature. This change should not be too difficult and should not be delayed unnecessarily.

Charles W. Jarvis, M.D.
St. Paul, Minnesota

Dear Editor:

I have enjoyed browsing through the January issue, as I always do, but I write you to protest that "herniae" (page 33) is very much like the story of the professor who said that his wife had so much laundry to do, that she needed two Bendices. I suggest that "hernia" has become an English word rather than a Latin one, and the plural is "hernias."

Harry L. Arnold, Jr., M.D.
Honolulu, Hawaii

Agree. Herniae are consigned to the classic rooms of Musea. Ed.

Allergic Reactions

I am compiling case reports of allergic reactions to biting insects, i.e., mosquitos, fleas, kissing bugs, bed bugs, gnats and flies—including horsefly, sandfly, deerfly. I am also interested in reactions to fire ants.

I would like physicians to supply me with case reports of those patients who have had reactions to such insects. Include in your reports, the history of the type of reaction and complications if any; the immediate treatment; if desensitization were attempted, what were the results? Send to:

Claude A. Frazier, M.D.
4-C Doctors Park
Asheville, N.C. 28801.

Claude A. Frazier, M.D.

Clinical Path Conference

A Steroid-Induced Infectious Complication of Rheumatoid Arthritis

George Kitzmiller, M.D.:

A 63-year-old man came to General Hospital in January, 1969, because of abdominal pain. Chronic deforming rheumatoid arthritis involving the fingers and ankles had been present since 1960 but controlled by prednisone, 15 mg. daily. Joint examination showed proximal interphalangeal joint hypertrophy; ulnar deviation of the fingers, and a warm, swollen left ankle. There was a mild normochromic, normocytic anemia with a reduced serum iron and iron binding capacity. Lumbar spine xrays showed chronic degenerative arthritis. A film of the left ankle revealed marked narrowing of the ankle mortis. Soft tissue swelling was suggestive of an acute pyogenic or tuberculous arthritis. A barium enema showed sigmoid colon diverticuli; and a clinical diagnosis of diverticulitis was made.

The patient was readmitted in February, 1969, for pre-olecranon bursitis and acute arthritis of the right wrist and left ankle. Cultures of the blood and draining joint sinuses showed penicillin-resistant staphylococci. Prostaphlin, 500 mg., and penicillin, 2,000,000 units, intravenously every six hours resulted in remission of fever and sinus drainage. Intermittent pain and swelling of the left ankle continued after discharge in late March, 1969.

After the admission on May 3, 1969, both preolecranon bursae were drained and the patient was treated with antibiotics. On May 10 he developed left lower quadrant abdominal pain and tenderness which increased on May 12. Subdiaphragmatic air was noted on x-ray. At operation an indurated abscess around the rectosigmoid was found and a collection of pus was present in the cul-de-sac. Penrose drains were placed in the pelvis and both colonic gutters, and sump drainage was inserted in the pouch of Douglas. A right transverse colostomy was performed.

Following surgery there was slow improvement until May 17, 1969, when the patient developed acute pulmonary edema. Subsequent serial electrocardiograms were compatible with an acute non-transmural myocardial infarction. This was treated with digitalis and diuretics, and he again began to improve slowly until May 23, 1969. At this time, intermittent confusion and lethargy were noted. These continued and on May 30, the confusion, incoherence, and hyperactivity became much more pronounced. On June 3, he developed coma and shock. After treatment with isuprel and plasma, urine volume and blood pressure were temporarily restored. Arterial blood Ph was 7.33; PCO 43 mm. of mercury; and PO2 67 mm. of mercury. The coma continued, shock recurred, and the patient died eight hours later. Accompanying Tables 1 through 4 detail the laboratory data, culture reports, and antibiotic and steroid therapy.

Clinical Discussion

Russell Payson, M.D.:

In evaluating this very complex history it should be noted that the patient had suffered from rheumatoid arthritis since 1960. A dosage of prednisone was maintained until his final illness without interruption. In January, 1969, he was seen here with abdominal pain and active joint disease. We are not told what happened to the ankle joint. I assume the non-operative management of the diverticulitis included antibiotics; so perhaps there was improvement.

Signs of acute septic arthritis recurred in February, 1969, and penicillin resistant staphylococci were cultured from the blood and draining sinuses. The patient was treated with Prostaphlin and intravenous penicillin with some improvement; however, intermittent joint symptoms persisted. Joint symptoms and drainage recurred three weeks prior to his final admission in May, 1969. Bowel perforation, pelvic abscess, acute pulmonary edema, and myocardial damage further complicated his clinical course. He appeared to improve on congestive heart failure medication but became confused and disoriented. Signs of mental confusion, incoherence, and lethargy persisted until death.

X-ray Discussion

Oscar Lipschultz, M.D.:

Xrays (Figure 1) of the left ankle in January 1969, revealed arthritis of the left ankle, which does not have the appearance of a rheumatoid or degenerative kind but is characteristic of an infectious type of arthritis. Soft tissue swelling and loss of joint space is present. An xray of the right elbow shows soft tissue swelling characteristic of a pre-olecranon bursitis.

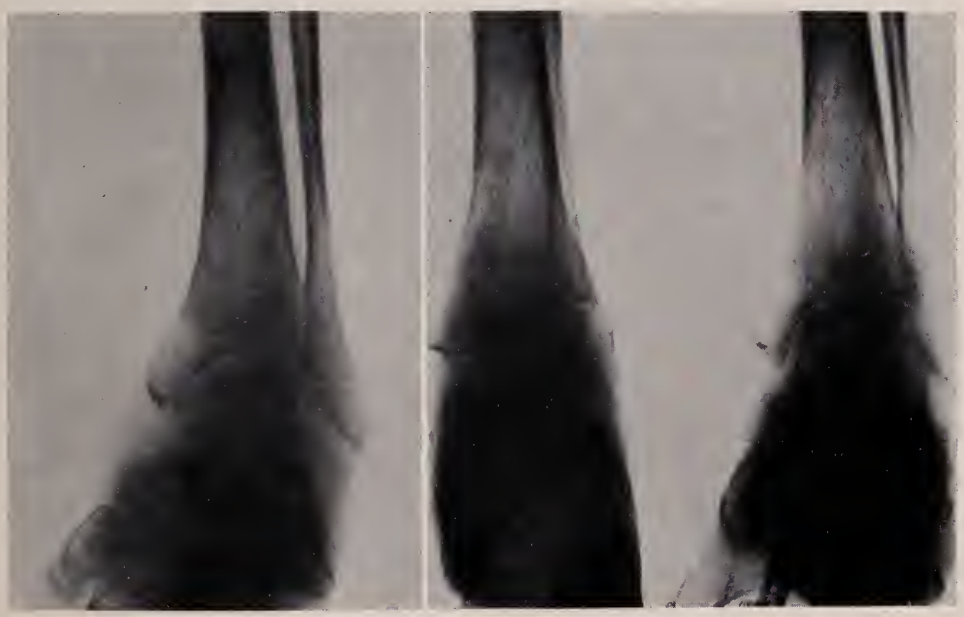

Fig. 1—Roentgenogram of ankle suggestive of septic arthritis.

A series of abdominal films also taken in January are suggestive of small or large bowel obstruction. A barium enema study on Janaury 19 confirmed the presence of sigmoid diverticulosis with associated acute diverticulitis.

We can use this film to show the lumbar spine which suggests an old fracture of the lumbar vertebra but does not suggest metastases or old rheumatoid spondylitis. We can also note a large distended bladder indicating paralysis of the bladder or improper emptying due to obstruction at the level of the prostate.

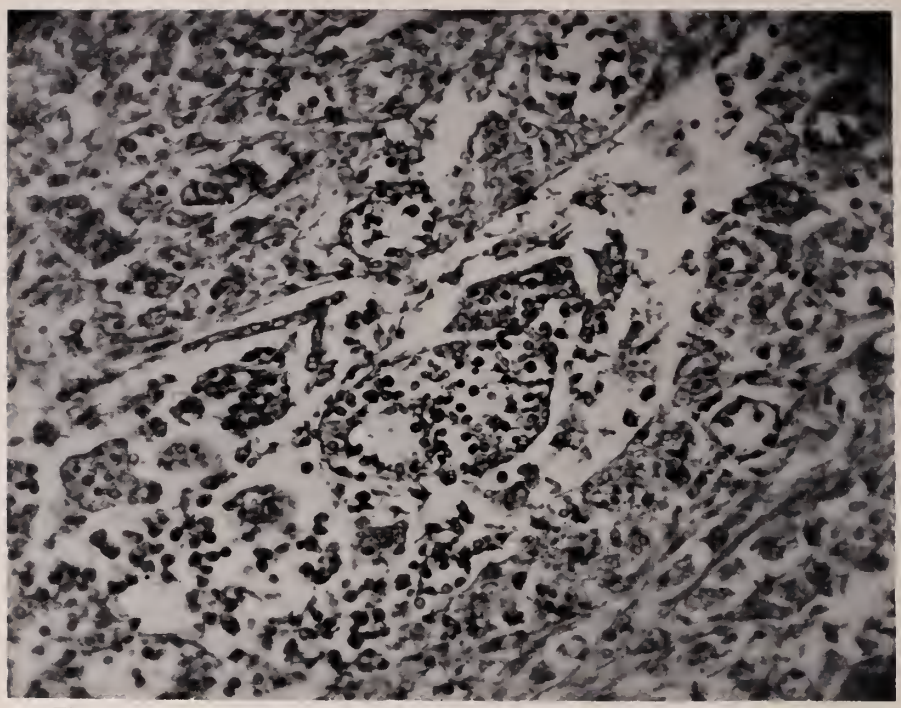

Fig. 2-X400 Prostate showing budding organisms of cryptococcus neoformans.

The admission chest x-ray on May 3, revealed a relatively normal chest with normal heart size. An abdominal film, taken on May 11 shows air under the left diaphragm. I assume that this film was taken just prior to surgery and was probably the basis for a diagnosis of rupture of an air-containing viscus.

On May 18 the patient developed a beautiful example of pulmonary edema with a typical butterfly appearance but without enlargement of the heart. One must also consider the possibility of an active bronchopneumonia at this time. Thereafter, the pulmonary roentgenographic studies progressively improved until near the time of death when there remained only a residual consolidation of the lower lobe.

In summary, the patient had an arthritis about the left ankle of an infectious type with abundant destruction; a pre-olecranon bursitis of the elbow, and pulmonary edema which improved most markedly on the final admission, leaving only a residual consolidation of the left lower lobe of the lung.

Discussion

Dr. Payson:

This is the first CPC I have ever seen in which the diagnoses listed in the protocol satisfactorily explain all the data. You can look at this man as a rheumatoid arthritis patient who developed multiple pyarthroses of the right wrist and the left ankle, followed by pre-olecranon bursitis, a common phenomenon in rheumatoid arthritis. The pre-olecranon bursitis is usually due to staphylococci which enter a break in the skin or mucosa, become a bacteremia, and settle in an area of inflammation about a joint. This is a particularly common phenomenon in patients with rheumatoid arthritis, especially those who have been treated with steroid therapy.

This patient also appears to have had well documented diverticulitis. He had a complicated course during his last admission, culminating in bowel perforation with pelvic abscess and surgery. Thereafter, he developed congestive heart failure and signs of a myocardial infarction. Further, he became disoriented, a fact not thoroughly explained in the protocol; but then he was anoxic and had congestive

heart failure. So there is really not much in the protocol that is not explained by the course of clinical events. It wouldn't be a challenge to stick with the diagnoses given to me; so I am going to discuss some other possibilities.

Differential Diagnoses

Rheumatoid Arteritis

The first diagnoses one might consider is rheumatoid arteritis, an entity which offers a good explanation for some of the events in the protocol. Rheumatoid arteritis is a phenomenon that occurs in association with rheumatoid arthritis, particularly in these patients who are treated with steroid medication. It most often occurs in older patients and is seen to closely mimic *periarteritis nodosa.* It may involve the bowel and cause infarcts, and it would be very difficult to *distinguish such bowel infarctions from acute diverticulitis.* It can also involve the coronary arteries and cause heart attacks; hence this would be a convenient link to tie things together in one package. It can also be associated with cerebral arteritis and lead to disorientation, confusion, and stroke symptoms.

Against this diagnosis is the absence of evidence of involvement of the skin or the nerves. There usually is some evidence of a neuritis or a neuropathy, which is not observed in this case. Areas of gangrene, particularly of the extremities, are quite common with rheumatoid arteritis, and these are not reported in this case. Gangrene of the extremities is encountered more commonly in rheumatoid arteritis than in periarteritis nodosa. The white count is usually not quite as high as was observed in our patient, but can go quite high. In view of the fact that we have staphylococci in the blood and in the joint fluid, I am disinclined to make a diagnosis that is not primarily infectious in origin.

Bacterial Endocarditis

I asked myself whether this man could have infective bacterial endocarditis: a favorite CPC diagnosis, particularly to a physician interested in infectious diseases. Infective endocarditis could explain a couple of the events in the clinical course. For instance, he could have had a coronary embolism to account for his episode of coronary thrombosis. Infective emboli could explain the infarction of the bowel with pelvic abscess and other evidence of embolic phenomena, particularly to the nervous system. However, he never developed red cells in his urine or splenomegaly, both of which may be expected with prolonged subacute bacterial endocarditis. The hemoglobin also remained remarkably stable, if one wishes to invoke the diagnosis of infective endocarditis. Most individuals with infective endocarditis show a prominent fall in the hemoglobin level. In addition, his blood urea nitrogen remained quite low until terminally.

Pyemia

I think what this man actually had is an old-fashioned disease which I call pyemia. We really don't encounter pyemia too frequently these days, but it is occasionally seen in individuals treated with steroids. Prior to the antibiotic era, pyemia was noted particularly as a complication of staphylococcal disease and resulted in multiple abscesses throughout the entire body, involving the heart or pericardium, and resulting in findings suggestive of myocardial infarction. In the brain pyemia caused multiple abscesses with and without meningeal involvement. In the lung one can see varying-sized pulmonary abscesses extending from very small abscesses to larger coalescent ones. The patient had a problem in the left base which might easily have been a series of abscesses from this process. The kidney is frequently involved, and this man did have pseudomonas in his urine in low numbers.

In this patient the organism responsible for pyemia could be *staphylococcus,*

and I think this *is the most common source of multiple abscesses.* He was never treated for his staphylococcal disease as adequately as we would like, and about the time of his operation he was getting nothing to counteract staphylococci. However, I am going to vote against staphylococcus because staphylococcal disease will usually not spread even though inadequately treated. It may enlarge and increase in the immediate area, but I would not expect new abscesses to develop. I am going to vote for pseudomonas just because it is a favorite organism of mine and because it appeared in the urine; I have seen pseudomonas act exactly this way on a number of occasions. It can spread. I have observed it in the heart and in the lungs, in the brain, and frequently in multiple liver abscesses. *Therefore I think pseudomonas is the most reasonable explanation for this man's disease.*

Steroid Therapy

This man needed steroids. We have to grant that steroids may have prevented long-term disability, and perhaps his eventual course was preferable to increased disability due to rheumatoid arthritis. However, when he came into the hospital with staphylococcal septicemia, I suspect that he might have done a little better if his steroid medication had been increased. A steroid dosage of 50 mg. a day is rather small. I would suggest that, since the life of solucortef is quite short, it might have been better to give him multiple doses rather than one shot a day. Then terminally, when he was getting very sick, I should think his dose would have been increased.

Antibiotic Therapy

The patient was known to have a staphlylococcal bursitis and a staphylococcal septicemia, but staphylococci were not cultured from the ankle. However, he had a clearly septic arthritis in the ankle with involvement of the bone, for which he received 500 mg. of prostaphlin q6hours intravenously. This is a dose that is used for minor infections. I myself would never use such a small dose because I don't treat trivial infections with antibiotics. I note that the penicillin dosage was much more reasonable; however, the organism was resistant to penicillin. In any event, he was sent home on prostaphlin alone. The total length of treatment was only three weeks. Osteomyelitis ordinarily should be treated for a number of months, if not years. In the treatment of his joint problems, the dosage was too little and the time too short.

Later the patient began to have abdominal problems and was given tetracycline and gantrisin. By this time, his condition must have become critical. I would strongly recommend using bactericidal drugs when a patient on steroids has a complicating infection. There was a period when this patient was getting only gantrisin and nothing for his staphylococcal disease or his diverticulitis.

Postoperatively he was treated with keflin 6 grams per day, which is certainly the least I would use for a patient this ill. Then Kantrex 450 mg. a day, which is the recommended dosage for a 30-kilogram man. This patient weighed more than that, the usual dose of Kantrex being 15 mg. per kilogram. Next he was placed on colymycin, 5 mg. per kilogram, a dosage appropriate for a desperately ill man. The dosage was then cut in half, which is not enough. I rushed to the laboratory values to see if he was developing elevation in his blood urea nitrogen as a result of the reduced dosage; however, that was not the case. He was finally placed on an adequate dose of keflin therapy prior to death; but by this time, if you will look on the sensitivity sheet, the organism was resistant to keflin. About the total antibiotic therapy; it appears that no one examined the whole spectrum of the disease and planned its progressive therapy.

Importance of a Lumbar Puncture

My next comment is directed to the fact that the patient became extremely disoriented about a week before he died. No lumbar puncture was done. The man was quite ill and had a number of reasons for developing mental symptoms such as anoxia and a low serum sodium. When a patient has evidence of generalized infection and develops mental symptoms, I would encourage a lumbar puncture. Certainly a complete neurological examination and a lumbar puncture are indicated in a case like this. Though our patient may not have had brain abscesses, such a possibility should nevertheless have been ruled out by a lumbar puncture. If he had pseudomonas in the meninges, of course, parenteral colymycin would not be effective and he would have had to be treated intrathecally.

My *final diagnoses* are (1) rheumatoid arthritis with staphylococcal pyarthroses involving the right wrist, left ankle, and pre-olecranon bursae and osteomyelitis of the spine; (2) diverticulitis with a pelvic abscess; (3) adrenal atrophy; (4) pyemia with metastatic infection of the heart, the lungs, the brain, and multiple other organs, probably due to pseudomonas species.

Pathology

Robert L. Strom, M.D.

It is a pleasure to have Russell back with us. We have been involved in a lot of verbal jousting about antibiotic therapy and I am sure this will resume and stimulate interest in the proper treatment of infectious disease in the institution. In defense of the antibiotic therapy, in the initial cultures on the joint there was also an anaerobic streptococcus and, because of this, the penicillin in high dosage may have been given mainly for this anaerobe. I think the anaerobic streptococcus again would suggest the possibility of an initial focus of infection in the colon, with extension into the blood stream and secondary infection of the joints.

Clinicians are very vigorous in their therapy with cortisone drugs which, in many cases, are a two-edged sword. Steroids are very helpful in relieving symptomatic discomfort; however, there are inherent risks and we must be ever alert for complications of steroid therapy.

This patient was extremely emaciated, weighing only 95 pounds. There were findings of the rheumatoid arthritis and evidence of a pelvic infection with drains in the pelvic region. The heart weighed 400 grams. Subendocardial hemorrhage was present, but no frank coronary thrombosis or myocardial infarction was found. We were interested in the myocardial process since the diagnosis of non-transmural myocardial infarction was made. The myocardial muscle itself looks quite normal but you will notice there is a perivasculitis. *Chronic myocarditis was present and this probably caused the electrocardiogram changes.* In addition, the patient had long standing rheumatic disease and we saw occasional small foci of perivascular scarring consisting of round cells with focal areas of fibrinoid change consistent with rheumatoid changes in the heart. There was no evidence of septic abscesses in the myocardium.

The lungs weighed approximately 1,000 grams combined weight and there was evidence of a *bronchopneumonia localized mostly to the left lower lobe.* The pneumonia apparently had been treated and was undergoing some resolution. I see no specific organisms or granulomas in the lung and I would assume that the infection in the lung represents a pyogenic rather than a mycotic infection.

The next thing that attracted our attention was heavy *pelvic adhesions in the area of diverticulitis.* Though this man had had a transverse colostomy, the infection did not totally subside. The cause of the bladder obstruction was a heavy infection of the prostate gland. Sometime prostatic gland infection leads to severe bladder neck obstruction. This infection of the prostate gland could be characterized as a

granulomatous prostatitis. One can see a number of granulomata in these areas of infected granulation tissue in the prostate itself. As we study the prostate in closer detail, much to our surprise we see lacunar spaces with small yeast-like organisms (Figure 2). There were 20,000 yeast organisms in the urine culture and I don't believe we followed up on them bacteriologically; I think we assumed they were Candida species. Closer observation of this infected prostate reveals a giant cell reaction and some mucopolysaccharide material within the giant cell reaction. A muci-carmine stain of the prostate shows multiple small budding yeast organisms which measure about 5-7 micra and are distributed throughout the prostate. These yeast organisms also take a PAS stain very vividly and, on this type of evaluation, one could consider a Candida or Cryptococcus type of organism. With the muci-carmine stain, however, the presence of a muci-carmine capsule suggests *cryptococcal prostatitis.*

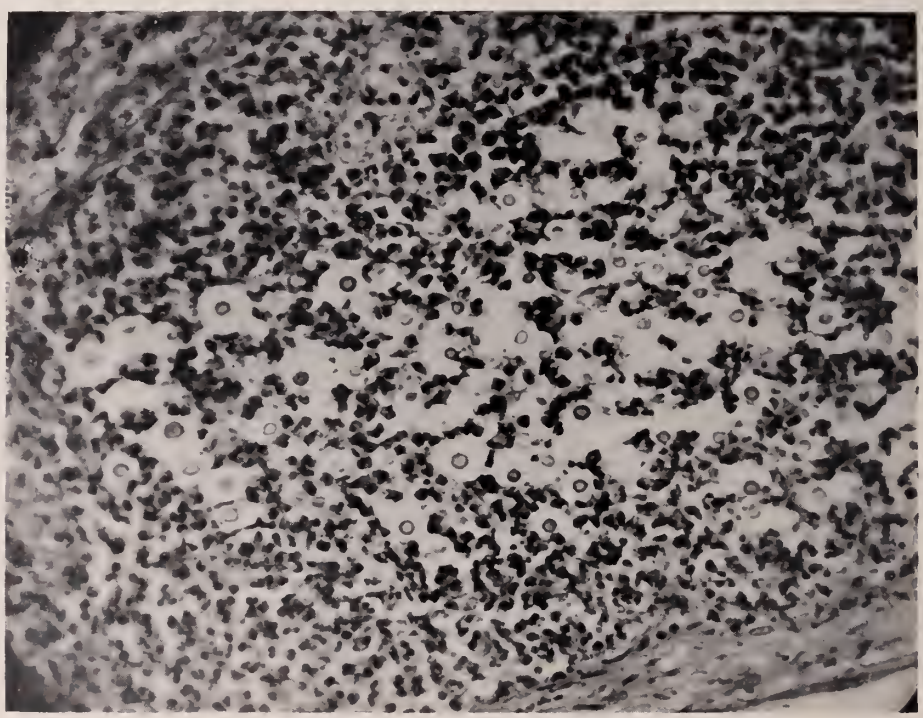

Fig. 3-X1000 Cryptococcal Meningitis.

Cryptococcal Meningitis

No spinal tap was done on this patient. He had symptoms of mental deterioration and confusion. If a spinal tap had been done, we would have seen on the India ink preparation the presence of budding yeast organisms with capsules around them diagnostic of cryptococcal meningitis. Individuals with cryptococcal meningitis have elevated spinal fluid cell counts, primarily of a lymphocytic type; an elevation of spinal fluid protein and a decrease in cerebrospinal fluid sugar. Spinal fluid cultures grow out Cryptococcus neoformans. This organism forms a mucoid colony much like Candida albicans. The fungi are easily differentiated by the production of urease by Cryptococcus neoformans.

Cryptococcus neoformans is responsible for a number of infections while patients are on steroid therapy. *When patients are infected with cryptococcal organisms, the mortality rate is extremely high.* Characteristically, the meninges are milky white, and fluid tends to loculate over the surface of the brain. When the brain is sectioned, one can see zones of necrosis extending in and around the cerebral sulci, into the basal ganglia, and surrounding the cerebellum.

In this case, a purulent meningitis was present, with many round cells and plasma cells, and within them we see yeast organisms (Figure 3). The meningitis surrounded the cerebral cortex and was most marked over the cerebellum. Within the purulent meningitis around the brain you can observe the red-staining PAS positive organisms in the meningitis. Such budding yeast organisms are characteristic of Cryptococcus neoformans.

Epidemiology of Cryptococcal Infections

Now for a few general comments about cryptococcosis. Approximately two thirds of these cases occur between the ages of 30 and 50 years. There is a very high incidence in white males and, in one series of 101 cases of cryptococcosis reported, 87% were in white individuals and 82% in men. *The reservoir for the infection is pigeon excreta.* We don't know the nature of our patient's occupation. Perhaps he was old enough to have spent a lot of time in the local parks and may have come in contact with pigeon excreta. Chester Emmons, who has done a number of epidemiologic studies of Cryptococcus organisms in soil, states that pigeon excreta contains up to 5 million Cryptococcus organisms per gram: a very potent source of infective organisms in the environment. Even in urban areas Cryptococcus can be prevalent because there are lots of pigeons and people have a tendency to protect them.

Cryptococcosis is an occupational disease in individuals who are pigeon tenders; but for some reason the Cryptococcus does not overtly infect the pigeons themselves. They carry it around their feet and on their bills but you do not find lesions of Cryptococcus in the pigeon flock itself. Obviously, it is in the gastrointestinal tract of pigeons and is being excreted. It has been said that possibly the high body temperature of the pigeon may account for the absence of organism growth.

Small white mice have been infected with Cryptococcus and this is a way of verifying the diagnosis. Cryptococcus is injected intracerebrally and, if you give the mice a little steroid, it helps the infection along very nicely.

We were slow to realize that individuals have a normal serum factor which is effective against Cryptococcus and that individuals on steroid therapy do not have this normal serum factor, as the therapy tends to deplete the factor. There are many predisposing factors of Cryptococcus infections; the most prominent ones we see clinically are Hodgkin's disease and lymphoreticular disorders. In a large series of cases up to 30% of the individuals with cryptococcal meningitis had Hodgkin's disease.[1] Leukemia, sarcoidosis, diabetes mellitus are frequent accompanying diseases. Rarely, rheumatoid arthritis and cirrhosis are associated with cryptococcosis, but in a case series studying the potentiation of cryptococcal infections with steroids, there were two cases of rheumatoid arthritis in six deaths reported. Generally these cases have had prolonged steroid therapy and the meningitis may be chronic; as the infection may last up to six months we have a good opportunity to positively diagnose it. Occasionally it is fulminant, as it apparently was in this case. This individual died perhaps two weeks after the onset of the headache and confusion.

These patients frequently have a primary focus in the lung due to Cryptococcus. The portal of entry is usually the lung with a hematogenous dissemination in the central nervous system. The prostatic infection in this case is of interest because of the intimate relationship between the venous plexuses of the prostate and the spinal canal and central nervous system. Because of this anatomic relationship the prostatic infection could have acted as a portal of entry to the central nervous sys-

tem. Our final pathologic diagnoses are (1) acute meningoencephalitis and acute prostatitis due to Cryptococcus neoformans; (2) bronchopneumonia left lower lobe; (3) chronic myocarditis due to rheumatoid arthritis; (4) chronic deforming rheumatoid arthritis; (5) acute pyogenic arthritis, left ankle, due to staphylococci.

Book Reviews

A book may be as great a thing as a battle.—Benjamin Disraeli,

PHYSIOLOGY OF WORK CAPACITY AND FATIGUE—Edited by Ernst Simonson. C. T. Thomas. Springfield, Ill. 571 pp., 1971. Cost: $33.50.

Ernst Simonson, professor emeritus of physiological hygiene, University of Minnesota and professor emeritus of physiology, Frankfort/Main, Germany, has had a lifelong and world wide interest in fatigue. He and a distinguished group of collaborators have gathered here in this book a comprehensive text on the subject with a bibliography of over 1500 titles. Undoubtedly the standard text on physiology of fatigue for this decade will be this work. Although the general nature of fatigue is well recognized, there are many features that are obscure. Theories of fatigue are discussed especially accumulation of substances producing fatigue and depletion of substances essential for activity.

This work is planned as one unit of a trilogy; the other subjects for future consideration being the psychology of fatigue and performance and fatigue in disease. Dr. Simonson currently is director of medical electronic research at Mount Sinai Hospital, Minneapolis.

Reuben Berman, M.D.
Minneapolis, Minnesota

HAZARDS OF MEDICATION; Author: Eric W. Martin, Ph.D.; Publisher: J. B. Lippincott Company, East Washington Square, Philadelphia, Pa. 19105; Pages: 895; Price: $27.50.

This book does indeed epitomize an overwhelming mass of literature on the subject of medication hazards. It comprises 10 chapters, which cover essentially the entire field of hazards that might be anticipated.

It is a volume that should be available on the doctor's shelf for ready reference in all instances wherein a medical incompatibility has developed or might be anticipated.

The Table of Drug Interactions is in itself comprehensive, its value appreciable, however, only when it is needed.

The book does not deal with clinical manifestations or symptoms associated with incompatibilities, but principally with the characteristics of the drug itself.

The volume's greatest value is that of reference.

Carl O. Rice, M.D
Minneapolis, Minnesota

CLINICAL OTOLOGY: Paparella M, Hohmann A, Huff J: An International Symposium. St. Louis, The C. V. Mosby Company, 249 pp., 1971, Price: $29.50.

Paparella, Hohmann, and Huff bring together in print the spirit and content of the University of Minnesota's international symposium of clinical otology held in June 1971. The subject matter represents the text of papers and the dialogue of televised surgical procedures of that meeting. As the input for this book was designated primarily for a symposium, the material is rather loosely arranged and is held together only by reference to the broad arena of otology and otologic research. For example, Huff's chapter on the preoperative preparation for ear surgery is followed directly by practical clinical audiology, trends in audiology, research findings of another audiometric test called stereoaudiometry, and then back to surgery for restoration of hearing. The subject arrangement makes the book more a collection of monographs than a text of clinical otology.

The attitudes surrounding the controversial areas of otologic surgery are colorfully and vividly communicated by the late Fred Guilford's discussion of current trends in tympanoplasty and is seconded by Schuknecht's comments on tympanoplasty. Both men had devoted much of their careers to the establishment of the principles of surgery for chronic suppurative ear disease. Perhaps they give themselves too little credit for systematizing these attitudes, with a dual emphasis on eradication of disease and the reestablishment of the mechanism of sound conduction. Both of these are worthy goals, neither exclusively paramount, and Guilford and Schuknecht have been extremely active in maintaining a reasonable perspective during a period of rapid change in otologic surgery. Their historic overview, their awareness of the false starts and haphazard trial and error methods of investigation, is nowhere better stated than in this collection of comments and surgical vignettes on tympanoplasty. Nevertheless, their dismay at the trends and anxiety over the mechanisms of teaching otology seem a bit overstated.

The price of this book is justified by the extra-ordinary assembly and correlation of history, physiology, and anatomy and ideas in H. L. Williams' contribution, "The Anatomic Principles of Mastoid Surgery." He ties together the speculation, observation, and controversy that sound the fundamental question of "Why the Chronic Running Ear?" This is Williams in print at his very best.

A clue to the next frontier of otology—the problem of sensory neural deafness—is provided by the final one fourth of the collective papers. Schuknecht's work on diseases of the inner ear, Duvall's work on sudden deafness, and Cody's work on treatment of sensorineural deafness provide a neat trilogy on this subject.

The text is a souvenir for those who attended the symposium and should be read by aspiring and practicing otologic surgeons. Medical students and nonotologic physicians would be confused, however, if they approached "Clinical Otology: An International Symposium" as a text of clinical otology.

Pre-Sate®
(chlorphentermine HCl)

CAUTION: Federal law prohibits dispensing without prescription.

Indications: Pre-Sate (chlorphentermine hydrochloride) is indicated in exogenous obesity, as a short term (*i.e.*, several weeks) adjunct in a regimen of weight reduction based upon caloric restriction.

Contraindications: Glaucoma, hyperthyroidism, pheochromocytoma, hypersensitivity to sympathomimetic amines, and agitated states. Pre-Sate (chlorphentermine hydrochloride) is also contraindicated in patients with a history of drug abuse or symptomatic cardiovascular disease of the following types: advanced arteriosclerosis, severe coronary artery disease, moderate to severe hypertension, or cardiac conduction abnormalities with danger of arrhythmias. The drug is also contraindicated during or within 14 days following administration of monamine oxidase inhibitors, since hypertensive crises may result.

Warnings: When weight loss is unsatisfactory the recommended dosage should not be increased in an attempt to obtain increased anorexigenic effect; discontinue the drug. Tolerance to the anorectic effect may develop. Drowsiness or stimulation may occur and may impair ability to engage in potentially hazardous activities such as operating machinery, driving a motor vehicle, or performing tasks requiring precision work or critical judgment. Therefore, such patients should be cautioned accordingly. Caution must be exercised if Pre-Sate (chlorphentermine hydrochloride) is used concomitantly with other central nervous system stimulants. There have been reports of pulmonary hypertension in patients who received related drugs.

Drug Dependence: Drugs of this type have a potential for abuse. Patients have been known to increase the intake of drugs of this type to many times the dosages recommended. In long-term controlled studies with high dosages of Pre-Sate, abrupt cessation did not result in symptoms of withdrawal.

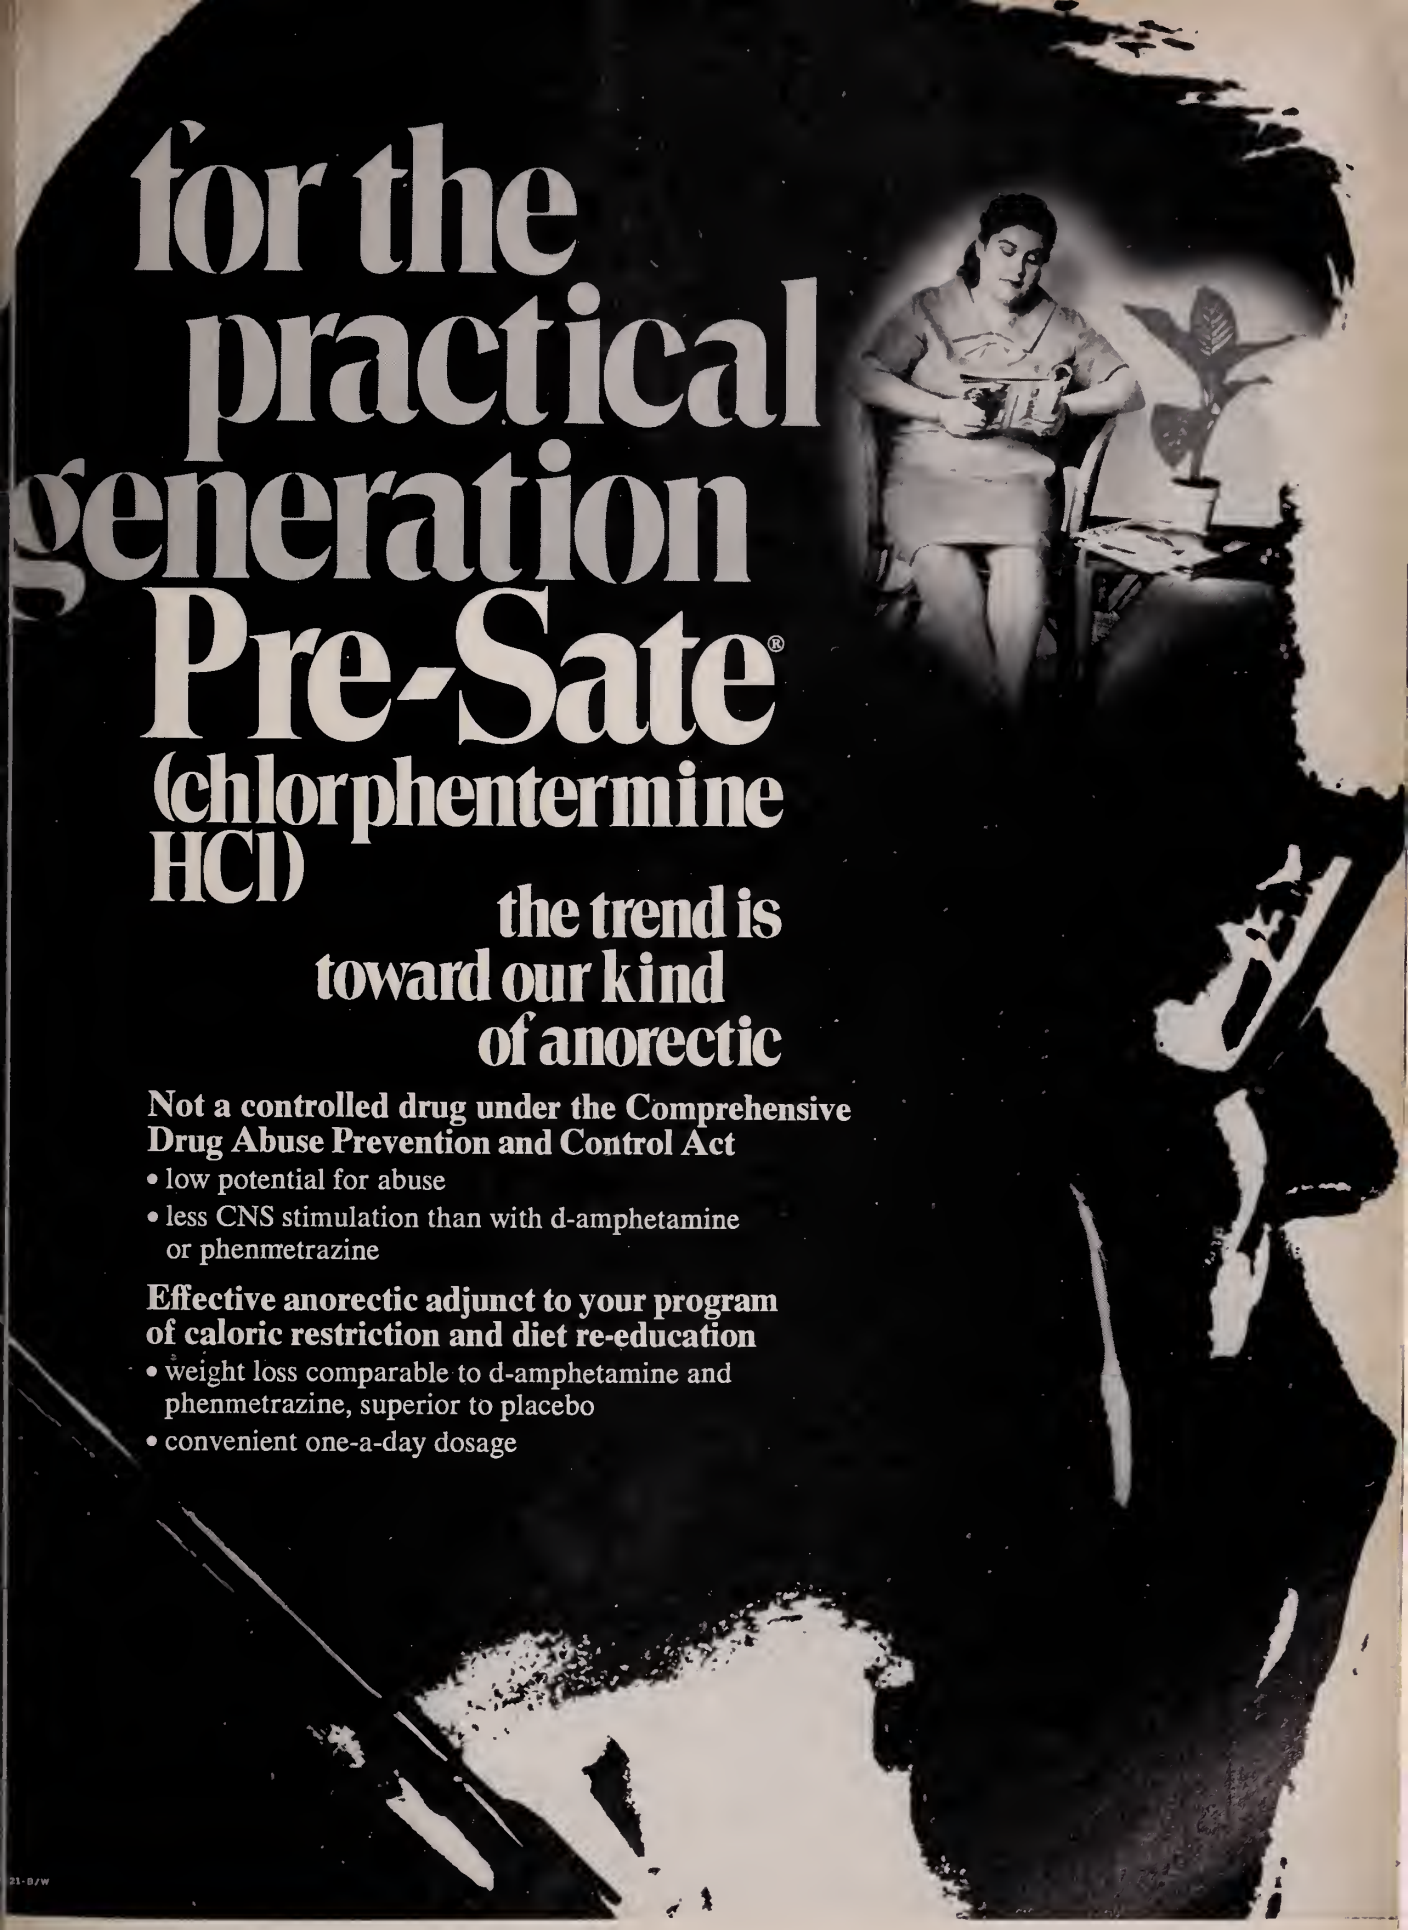
Usage In Pregnancy: The safety of Pre-Sate (chlorphentermine hydrochloride) in human pregnancy has not yet been clearly established. The use of anorectic agents by women who are or who may become pregnant, and especially those in the first trimester of pregnancy, requires that the potential benefit be weighed against the possible hazard to mother and child. Use of the drug during lactation is not recommended. Mammalian reproductive and teratogenic studies with high multiples of the human dose have been negative.

Usage In Children: Not recommended for use in children under 12 years of age.

Precautions: In patients with diabetes mellitus there may be alteration of insulin requirements due to dietary restrictions and weight loss. Pre-Sate (chlorphentermine hydrochloride) should be used with caution when obesity complicates the management of patients with mild to moderate cardiovascular disease or diabetes mellitus, and only when dietary restriction alone has been unsuccessful in achieving desired weight reduction. In prescribing this drug for obese patients in whom it is undesirable to introduce CNS stimulation or pressor effect, the physician should be alert to the individual who may be overly sensitive to this drug. Psychologic disturbances have been reported in patients who concomitantly receive an anorexic agent and a restrictive dietary regimen.

Adverse Reactions: Central Nervous System: When CNS side effects occur, they are most often manifested as drowsiness or sedation or overstimulation and restlessness. Insomnia, dizziness, headache, euphoria, dysphoria, and tremor may also occur. Psychotic episodes, although rare, have been noted even at recommended doses. **Cardiovascular:** tachycardia, palpitation, elevation of blood pressure. **Gastrointestinal:** nausea and vomiting, diarrhea, unpleasant taste, constipation. **Endocrine:** changes in libido, impotence. **Autonomic:** dryness of mouth, sweating, mydriasis. **Allergic:** urticaria. **Genitourinary:** diuresis and, rarely, difficulty in initiating micturition. **Others:** Paresthesias, sural spasms.

Dosage and Administration: The recommended adult daily dose of Pre-Sate (chlorphentermine hydrochloride) is one tablet (equivalent to 65 mg chlorphentermine base) taken after the first meal of the day. Use in children under 12 not recommended.



Overdosage: Manifestations: Restlessness, confusion, assaultiveness, hallucinations, panic states, and hyperpyrexia may be manifestations of acute intoxication with anorectic agents. Fatigue and depression usually follow the central stimulation. Cardiovascular effects include arrhythmias, hypertension, or hypotension and circulatory collapse. Gastrointestinal symptoms include nausea, vomiting, diarrhea, and abdominal cramps. Fatal poisoning usually terminates in convulsions and coma.

Management: Management of acute intoxication with sympathomimetic amines is largely symptomatic and supportive and often includes sedation with a barbiturate. If hypertension is marked, the use of a nitrate or rapidly acting alpha-receptor blocking agent should be considered. Experience with hemodialysis or peritoneal dialysis is inadequate to permit recommendations in this regard.

How Supplied: Each Pre-Sate (chlorphentermine hydrochloride) tablet contains the equivalent of 65 mg chlorphentermine base; bottles of 100 and 1000 tablets.

Full information available on request.

bler Landscape"

Donald C. Bell, M.D.

JUNE, 1972

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counselin

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

ROCHE
Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

Valium®
(diazepam)

To help you manage excessive psychic tension

Prompt relief of pain is a lot of what the practice of medicine is all about... East or West.

In much of the Far East, the analgesic efficacy of Empirin® Compound with Codeine would probably be measured against acupuncture, an ancient and traditional therapeutic system.

In America, codeine sets such a high standard for oral analgesia, that it has become a criterion in terms of which other major oral analgesics are most often measured.

Synthetic and other oral analgesics may offer some of the properties of codeine, but not one can provide both its benefits and potency. And codeine provides an antitussive bonus.

Empirin Compound with Codeine is the most widely used, and probably the most pharmaceutically elegant analgesic preparation providing codeine. It's the time-tested combination for predictable pain relief . . . whether the pain is visceral or musculoskeletal; acute or chronic.

New prescription flexibility. At your discretion, and where state law permits, a prescription for Empirin Compound with Codeine may now be refilled up to five times in six months.

Empirin Compound with Codeine No. 3 contains codeine phosphate (32.4 mg.) gr. ½. No. 4 contains codeine phosphate* (64.8 mg.) gr. 1. *(Warning—may be habit-forming.) Each tablet also contains: aspirin gr. 3½, phenacetin gr. 2½, caffeine gr. ½. Bottles of 100 and 1000.*

But for relief of Western pain

if skin is infected, or open to infection...

choose the topicals that give your patient–

- broad antibacterial activity against susceptible skin invaders
- low allergenic risk—prompt clinical response

Special Petrolatum Base
Neosporin® Ointment
(polymyxin B-bacitracin-neomycin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 5000 units; zinc bacitracin, 400 units; neomycin sulfate 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q. s.
In tubes of 1 oz. and ½ oz. for topical use only.

Vanishing Cream Base
Neosporin®-G Cream
(polymyxin B-neomycin-gramicidin)

Each gram contains: Aerosporin® brand polymyxin B sulfate, 10,000 units; neomycin sulfate, 5 mg. (equivalent to 3.5 mg. neomycin base); gramicidin, 0.25 mg., in a smooth, white, water-washable vanishing cream base with a pH of approximately 5.0. Inactive ingredients: liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax, purified water, and 0.25% methylparaben as preservative.
In tubes of 15 g.

NEOSPORIN for topical infections due to susceptible organisms, as in impetigo, surgical after-care, and pyogenic dermatoses.

Precaution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: Not for use in the external ear canal if the eardrum is perforated. These products are contraindicated in those individuals who have shown hypersensitivity to any of the components.

Complete literature available on request from Professional Services Dept. PML.

Wellcome / Burroughs Wellcome Co.

rheumatoid arthritic blowup...

Tandearil® Geigy

oxyphenbutazone NF tablets of 100 mg.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete hemogram, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, avoiding those responsive to routine measures, contraindicated patients or those who cannot be observed frequently. Warn patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals or a full glass of milk. Patients should discontinue the drug and report immediately any sign of: fever, sore throat, oral lesions (symptoms of blood dyscrasia); dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin reactions, significant weight gain or edema. A one-week trial period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.
Indications: Acute gouty arthritis, rheumatoid arthritis, rheumatoid spondylitis.
Contraindications: Children 14 years or less; senile patients; history or symptoms of G.I. inflammation or ulceration including severe, recurrent or persistent dyspepsia; history or presence of drug allergy; blood dyscrasias; renal, hepatic or cardiac dysfunction; hypertension; thyroid disease; systemic edema; stomatitis and salivary gland enlargement due to the drug; polymyalgia rheumatica and temporal arteritis; patients receiving other potent chemotherapeutic agents, or long-term anticoagulant therapy.
Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, and concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially the aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use lowest effective dosage. Weigh initially unpredictable benefits against potential risk of severe, even fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.
Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.
Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia, gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angiitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement.

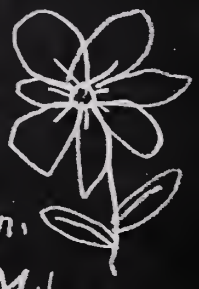
President's Letter

People

THE COMPOSITION of one's first public message to his peers as President of our Association causes a great deal of contemplation on many critical and potentially explosive problems currently facing all of us. What should a president do? Be a strong outspoken leader gathering his followers for battle? Be cautious, play it cool, issue the old time-worn platitudes and cliches? None of these seem appropriate now.

For right at this time, I am feeling sympathy for those of our fellow humans who for one reason or another, i.e. lack of health education, transportation, poverty, etc., cannot find or properly utilize existing medical and health care. I feel angry at those who expolit this situation for personal or political gain and I feel compassion for all who are honestly trying to find solutions. The frustration resulting from fatigue and hopeless striving to care for more and more people and the agony of re-evaluating medical and health manpower education and its distribution are no strangers to me. I am aware of the feeling of responsibility also. The responsibility to do what is possible to fulfill the purposes stated in the Minnesota State Medical Association constitution, "the purposes of this corporation shall be community welfare, community health and scientific education—promoting the science and art of medicine, elevating the standard of medical education so that the profession shall become more capable and honorable within itself and more useful to the public in the prevention and cure of disease and adding to the comforts of life;—prevention of disease and promotion of the public health; assisting officials and agencies of the state of Minnesota with advice and service in the administration of its medical, hospital, welfare and public health programs; promoting high standards of medical and health service in all public programs established for the welfare of the people of Minnesota," so it appears that it is people and their quality of life that our Association is dedicated to by promoting the art and science of medicine.



My message to you then is PEOPLE! Human beings with all their strengths and frailities; human beings, the beginning of each a point in time and the demise likewise, and their course and destination can only be surmised. Shall we share this humanness, you and I? Sharing our concerns may alter the course and increase the quality of time between the beginning and ending, the period we call life, for us and those we touch. I believe this to be true. I believe that this is what being a physician is all about.

George B. Fratten

President
Minnesota State Medical Association

"The history of science, and in particular the history of medicine... is... the history of man's reactions to the truth, the history of the gradual revelation of truth, the history of the gradual liberation of our minds from darkness and prejudice."

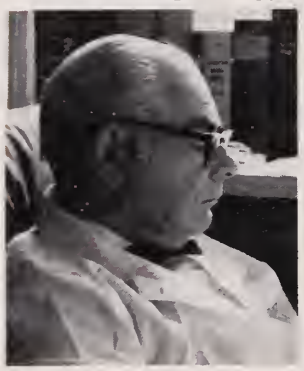
—George Sarton, from "The History of Medicine Versus the History of Art"

Would it be useful in clinical practice to have government predetermine drugs of choice?

Opinion

Results of a survey of physicians:

13.3%
Yes, it would be useful.



86.7%
No, it would not be useful.

Dialogue

Would it be useful in clinical practic to have government predetermine drugs of choice?

Doctor of Medicine

Walter Modell, M.D.,
Professor of Pharmacology,
Cornell University
Medical College,
Editor,
Clinical Pharmacology
& Therapeutics,
Drugs of Choice,
Rational Drug Therapy

The proposition that government should determine one or two "drugs of choice" within a given therapeutic class reflects the belief that a similarity in molecular structure insures a close similarity in pharmacologic effect. But this is by no means the rule. An obvious example would be in the field of diuretics, where a small change in chemical structure accounts for substantial differences in concomitant effects such as potassium excretion.

Any attempt to dictate the "drug of choice" would be complicated by the fact that some populations demonstrate a bimodal distribution in their reaction to drugs. If the data on drug response are mixed for the total population, one drug will appear to be as useful as the other. But if drug response is reported separately for different segments of the population, drug A will be found to be better for one group and drug B for the other.

It may, of course, be possible to determine drugs of choice in particular categories on a broad statistical basis. But there are always certain patients in whom a drug produces odd, unpredictable or idiosyncratic reactions. So, though a drug might statistically be the most useful one in a given situation, individual variations in response might make it the *incorrect* one.

The point I wish to make is that if two, three, four or more drugs in one class are of approximately equal merit, that in itself is justification for their availability. Exceptional cases do arise in which one drug would be useful to a certain segment of the population and another drug would be of no use at all. In the practice of medicine, the physician must be prepared to treat the routine as well as the unusual case.

Another objection to the determination of a drug of choice is that precise statements of *relative* efficacy are very difficult to make—much more difficult than statements of efficacy. For example, in testing drug efficacy, it is easy to determine the difference between a drug that is effective in treating a condition and one that is not at all effective. Thus, it is fairly easy to determine whether a drug is more effective than a placebo. But if you compare one drug that is effective with another drug that is also effective, and the relative differences between them are very slight, statements of relative efficacy may be very difficult to make with assurance.

I do not mean to imply that relative efficacy statements are not useful or can never be made. With some groups of drugs (e.g., analgesics), extensive study and precise methodology have yielded useful information on relative efficacy. But in most situations, such information can be acquired only through studies encompassing three to five years of use in many more patients than are used to compare drugs with a placebo for the introduction of a drug into commerce. It is really only after practitioners use a drug extensively that relative safety and efficacy in practice can really determined.

The Bureau of Drugs suggested the package sert as a possible mean communicating informa on relative efficacy of d to the physician. I find objectionable, since I not believe the physi should have to rely on source for final scien truth. There is also a p tical objection: Since physicians actually pense drugs, they sel see the package insert any event, I would m tain that the physic should know what dru wants and why without pending on the governm or the manufacturer to him.

Undoubtedly, physic are swamped by exces numbers of drugs in s therapeutic categories. I am well aware that m drugs within such c gories could be elimin without any loss, or haps even some profit the practice of medic But, in my opinion, nei the FDA nor any o single group has the ex tise and the wisdom ne sary to determine the "drug of choice" in areas of medical practi

Maker of Medicine

Kenneth G. Kohlstaedt, M.D.,
Vice President,
Medical Research,
Eli Lilly and Company

In my opinion, it is not the function of any government or private regulatory agency to designate a "drug of choice." This determination should be made by the physician after he has received full information on the properties of a drug, and then it will be based on his experience with this drug and his knowledge of the individual patient who is seeking treatment.

If an evaluation of comparative efficacy were to be made, particularly by government, at the time a new drug is being approved for marketing, it would be a great disservice to medicine and thus to the patient — the consumer. For example, when a new therapeutic agent is introduced, on the basis of limited knowledge, it may be considered to be more potent, more effective, or safer than products already on the market. Conceivably, at that time the new drug could be labeled "the drug of choice." But as additional clinical experience is accumulated, new evidence may become available. Later, it may be apparent that the established products should not be so easily dismissed.

Variation in patient response to drugs constitutes one of the major obstacles to the determination of "drugs of choice." We are just beginning to open the door on pharmacogenetics, but it is evident that genetic differences cause wide variations in the way drugs are absorbed, metabolized, etc. This fact alone is sufficient to make unrealistic the idea that there is one drug in each class to be used for every human being.

The problem of determining relative drug efficacy is an extremely complicated one. Comparison with other drugs of the same class should not be a prerequisite for marketing a new substance. In some therapeutic areas, it may be difficult to make accurate comparisons. For example, in the treatment of infections it is not possible to conduct crossover studies. Recovery may be influenced by factors which cannot be controlled or measured, i.e., natural host resistance and virulence of infective agents. A drug's acceptability must often be judged on the basis of its own performance, and this may be limited to experience in a relatively small patient population. If the introduction of a new drug must await the adequate establishment of relative efficacy, the duration of clinical trial and extent of studies would be greatly prolonged, particularly for rare or unusual conditions. The availability of a new drug would be delayed. Many patients might suffer needlessly and lives might be lost.

Relative efficacy can best be established by experience in a general patient population through regular channels of clinical practice. The physician considers the patient as a whole, which means the patient often has multiple problems and drugs must be selected with this in mind. Hence, a "drug of choice" in an uncomplicated case may not be the best drug for a patient with associated problems. Publication of well-controlled studies in medical journals may provide comparative evidence; discussions at medical meetings, presentations at postgraduate courses, and the new audiovisual technology may bring evidence to physicians on comparative therapy. In a free medical marketplace, a drug that does not measure up will fall into disuse. For example, broad clinical experience has established vitamin B_{12} as the "drug of choice" for the treatment of primary pernicious anemia. No amount of advertising or promotional effort by the manufacturer could increase the use of liver extract for this anemia. However, a physician may wish to employ parenteral liver preparations for a special purpose.

In the field of surgery, peer review in the hospital has brought significant improvement in the use of new techniques and procedures. Something of this nature would be useful in the area of drug therapy. However, it should be developed by the medical profession itself and would necessitate, for its proper function, an improvement in the dissemination of reliable data on clinical pharmacology of drugs under consideration.

Ideally, information on the relative efficacy of drugs should be gathered and assessed by the physicians who actually administer the specific agents to a specific patient population. To do this, they will need even more information on the drugs they use — information that the pharmaceutical manufacturers must begin to provide if government regulation of *"drugs of choice"* is to be avoided.

Idiopathic Scoliosis

Current Concepts in the Treatment

ROBERT B. WINTER, M.D.,* and JOHN H. MOE, M.D.†

SCOLIOSIS, ONCE considered the scourge of orthopedics, has entered a new phase. In the past, treatment of this condition was so poor that one could only stand by and watch the curve get worse. Finally, when it got bad enough, a difficult fusion operation was done as a last resort. Such pessimism no longer has a place in the treatment of this condition, and the entire concepts of treatment have changed within the past ten years.

History

Before 1900 the only treatment for curvatures of the spine was various exercise programs. These did little to correct or prevent progression of these curvatures. The benefit derived from them was that both doctor and parents thought that something was being done. Subsequent studies, particularly those of the subcommittee of the American Orthopedic Association in the 1940's, proved conclusively that exercises *alone* do not affect either the severity or the progression of curvatures of the spine in the growing child.

Hibbs in 1911 published a paper on fusion of the spine for tuberculosis. Within a few years the same operation was adopted to the treatment of curvatures of the spine. Over the years there was a gradual acceptance of spine fusion as a satisfactory method of treatment for curvatures of the spine. Various refinements in casting and fusion technique evolved through the efforts of such men as Cobb, Risser, and Von Lackum. Thus a good method of treatment of a sufficiently developed curvature became available. The problem was that there was no treatment for the mild curve until it reached the point where surgery was considered indicated.

In the late 1940's Blount and Schmidt of Milwaukee began designing the Milwaukee Brace. At first, it was used only as a recumbent postoperative frame particularly for patients undergoing spine fusion for poliomyelitis scoliosis. In the 1950's it became apparent that when properly made and properly applied this brace was effective *as a non-operative, ambulatory method* in the treatment of idiopathic scoliosis.

About 1960 Paul Harrington of Houston, Texas, developed a set of instruments to facilitate the internal correction and internal support in the process of spine fusions. These are universally known as Harrington instruments, and have become widely used as a part of the fusion operation.

General Aspects of Idiopathic Scoliosis

Idiopathic Scoliosis, as its name implies, has escaped adequate knowledge as to the specific nature of the condition. However its clinical features are so well known and follow such characteristic patterns that its definition as a specific disease entity cannot be questioned. Prior to the use of vaccines, it was thought to represent a "subclinical" case of poliomyelitis. There has been no diminution in the incidence of idiopathic scoliosis through the use of poliomyelitis vaccines, and this theory must be discarded. Other authors have felt that dietary abnormalities and restrictions were etiologically significant. This seems to be ruled out by the consistency of the disease in countries of varying socioeconomic backgrounds and dietary conditions.

Classification

Idiopathic Scoliosis is divided into three categories based on the age of appearance.

1. *Infantile,* appearing under the age of three. This type is rarely seen in the United States, but is frequent in Great Britain and of Europe. It is usually a curve to the left, usually in boys. In 90% of cases it is self-curing in which case the curvature is gone by the age of two. Ten per cent of the curves progress, are not self-curing, and become severely crippling conditions, requiring

Fig. 1D—An Xray showing her correction 15 months after surgery.

prolonged and aggressive treatment.

2. *Juvenile,* appearing between the age of three and puberty. This is a relatively less common time for the appearance of this disease; however, when it does occur, it is never self-curing, and because of the many years of growth remaining, tends to produce a very unsightly and crippling condition. Again, aggressive and unrelenting treatment is necessary.

3. *Adolescent,* appearing between puberty and the completion of spinal growth. In the United States, this is the most common type. Contrary to infantile idiopathic scoliosis, adolescent idiopathic scoliosis occurs almost exclusively in girls, and most commonly produces a right thoracic curve. It is usually steadily progressive from the time of appearance until cessation of spinal growth, usually about age 16 or 17. Since there are a fewer number of years in which this progression can occur, the final result is usually not as catastrophic as with juvenile or infantile idiopathic curvatures. Nevertheless, significant deformities occur, and treatment cannot be ignored.

Fig. 1E—The patient age 14, just prior to surgery (left) and (right) 15 months after surgery.

Complications

In addition to the cosmetic deformities produced by these curvatures, it has become increasingly apparent that significant alterations in the pulmonary function and cardiac status can result from curvatures of the spine. Deformity of the thorax results in a loss of usable lung space, and secondarily results in a shunting of blood through the pulmonary circulation without adequate oxygenation. Pulmonary function studies in the past have been too unsophisticated to detect these early abnormalities, but recent techniques measuring intra-arterial oxygen tension and perfusion-ventilation studies using radioactive xenon, have shown these defects in pulmonary physiology much earlier and with much smaller curves. A recent study by Nachemson in Sweden has shown that there is a 100% increase in mortality in patients with thoracic scoliosis after the age of 40.

Genetics

Dr. Ruth Wynn-Davies of Edinburgh, Scotland, showed in a general population study of 11,000 Edinburgh School students, that there was an incidence of early onset scoliosis (under the age of eight) of 1.3 per thousand students. Late onset scoliosis (over the age of eight) occurred at an incidence of 1.8 per thousand students. Of those patients with scoliosis, all of the first, second, and third degree relatives were examined, a study of over 2,000 individuals. Approximately 25% of the patients had a positive family history of scoliosis. The genetic factor appeared to be stronger for the late onset scoliosis than for the early onset scoliosis.

Drs. Cowell, Hall, and MacEwan from DuPont Institute, Wilmington, Delaware, showed in a recent detailed study of 100 families in which one child had scoliosis, that in eighty per cent of the families a sibling or parent had scoliosis. Many of these were not aware that they had a curvature, but when Xrayed, were found to have this condition. There appeared to be a sexlinked dominant mode of inheritance, as there was no male to male transmission documented. It seems evident, from these studies, that a strong genetic factor is present in this disease.

Fig. 2A—A 13-year-old female with a 100° curve from the fifth thoracic to the first lumbar vertebra.

Fig. 2B—The same girl at age 17, four years after surgical correction of the deformity.

Treatment

There are three ways to treat these curvatures. The *first* is to do nothing, except to observe the child periodically, including the taking of Xrays to see whether a curve is present, or if present, whether it is progressive. This type of "observational treatment" is rarely justifiable. *As noted previously, physical therapy and exercises do not, have not, and never will correct an already present curvature of the spine.* Exercises *are* important when properly combined with a Milwaukee Brace or fusion program.

The *second* form of treatment is fusion. This has definite indications, and is used when the patient presents already having completed growth, and with sufficient deformity so that treatment is necessary. The Milwaukee Brace is not effective in treating the fully grown individual. Fusion remains the only available choice for this type of patient. The second indication is the patient with a curvature that is beyond the ability of the brace to treat. These sometimes require fusion, regardless of the age of the patient.

Arthrodesis of several segments of the spine (the fusion operation) plays an important part in the treatment program. Unfortunately, many children do not have their curvatures detected by their parents or family physician until they reach

Fig. 2C—Her appearance (left) just prior to surgery and (right) four years after surgery. She spent nine months in a cast.

Fig. 3A—A 15-year-old male with a double curve pattern, right thoracic and left lumbar.

Fig. 3B—The same boy three years later at age 18. Surgical correction by Harrington Instrumentation and spine fusion T3-L4.

a serious degree of curvature. At other times, even more unfortunately, the pediatrician or family physician will note the presence of a curvature and state "it isn't so bad, and I don't think it will get worse", only to have the child come to the orthopedist several years later with a crippling deformity. Advances in the fusion operation are primarily those of the Harrington instruments for gaining internal correction and internal stability. This has provided a lowered incidence of pseudoarthrosis and permit early ambulation. We are now ambulating most of our patients in casts as early as six days after surgery, compared to our previous practice of keeping patients in bed for six months. Even with the instruments it is necessary to keep the patient in a cast for at least nine months after the operation.

The *third* form of treatment is the use of the Milwaukee Brace. This brace has proven very effective in the treatment of idiopathic curvatures, *providing that the cihld is still growing,* and *that the curve is not too severe.* The Milwaukee Brace has become an increasingly important tool in the treatment of these curvatures. This has evolved from our greater understanding of its capabilities and limitations. It also evolves from our greater ability to make a good brace, and with greater

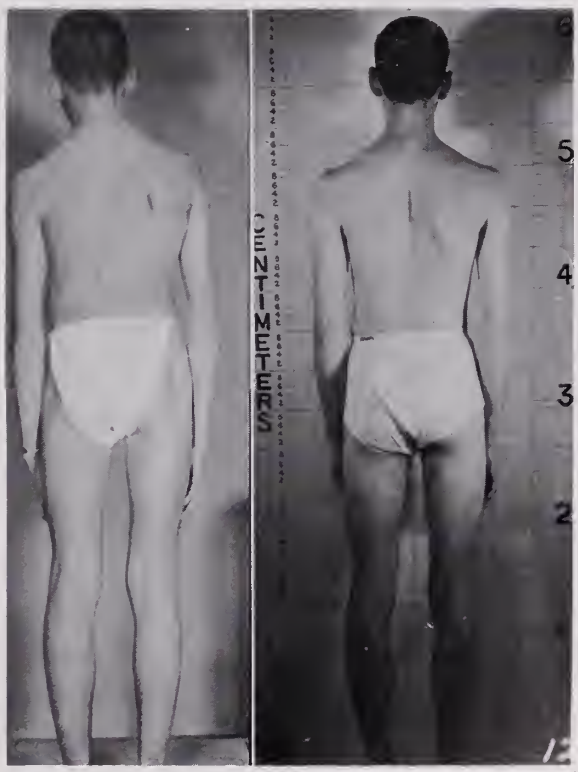

Fig. 3C—Preoperative photograph, age 15 (left) and postoperative photograph, age 18 (right).

Fig. 4A—A 10-year-old female with a progressive curve. The curve had measured 45° three months previously.

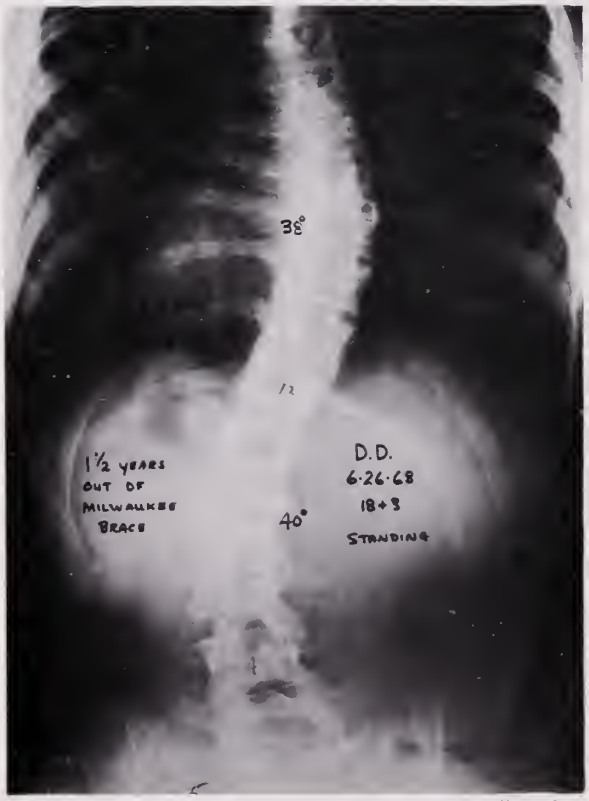

Fig. 4B—The same girl, age 18. She wore a Milwaukee Brace from age 10 until age 16.

understanding on how to use the brace. The brace will prevent progression of most idiopathic scolioses. Therefore, when applied *early enough,* worn *long enough,* and removed *slowly enough,* the curvature will be completely halted in its progression and never reach a significant degree of curvature.

The physician must apply the brace at a time when the curvature is minimal enough to respond to the brace. From a practical point of view, it has been our experience that almost no curvatures under 40° (by the Cobb technique) will ever require surgery, if properly treated with a Milwaukee brace. This is *not* to suggest that we wait until the curve reaches 40°. The brace should be applied when the curves are small, preferably when about 15°-20°. Under 15°, treatment is not justifiable and permitting a child to progress from 20°-40° before starting treatment is indefensible, since this progression can rarely be retrieved.

Discussion

Advances in the past ten years have removed most of the fears of idiopathic scoliosis. It has now become a treatable condition with a good prognosis. When detected early by routine examination of the spine by the family physician or the pediatrician, treatment can be instituted with a Milwaukee Brace. Providing that the patient is cooperative about wearing the brace, a good prognosis can be anticipated and surgery avoided.

Fig. 4C—Photograph of this girl at the time treatment was started (left). It is easy to see how these curves can be missed by casual observation. Her appearance at age 18 (right). She has no pain, no scar, normal spine motion, and was never hospitalized.

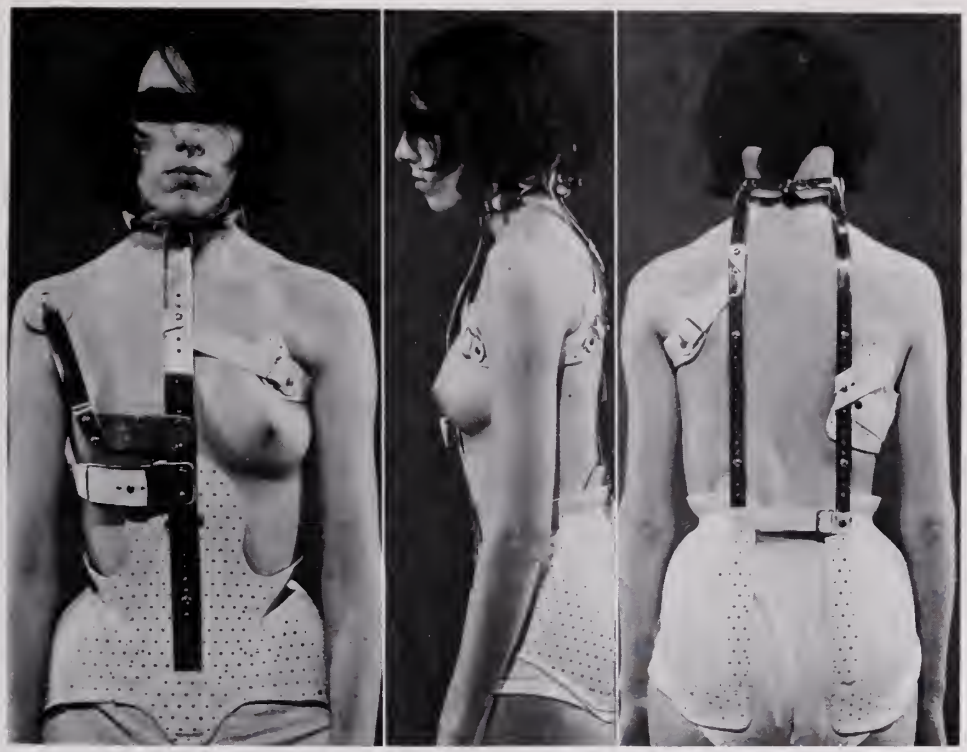

Fig. 5—A modern Milwaukee Brace. It is perfectly comfortable and causes no pressure on the teeth or jaw (a frequent criticism of earlier such braces). The child can participate in all activities except tumbling, trampoline, and football.

When the patient presents with an already significant deformity, beyond the ability of the brace to correct, good fusion operations are now available, and, again, a good prognosis can usually be rendered. A fusion is a serious, major orthopedic operation, and carries with it a significant number of complications. We feel the brace treatment is always preferable, providing the curve is responsive to the brace. In some instances, it is borderline whether a curvature will or will not respond to the brace. Under these circumstances, it is best to try the brace for six to 12-months, and if it fails, then proceed with surgery.

Summary

A better understanding of idiopathic scoliosis is now available, and the genetic nature of the disease has become increasingly obvious.

A pessimistic "watch and wait" attitude can no longer be condoned.

Early treatment of minimal to mild curves with the Milwaukee Brace has proven to be our most effective treatment. This gives the child a functionally excellent spine, an excellent cosmetic appearance, and avoids the need for extensive surgery.

When surgery is necessary, good technique has now given us a high rate of success, with a minimum number of complications.

The treatment of scoliosis has reached a new era, in which optimism and enthusiasm have now replaced the gloom and despair of former years.

Falstaff: Sirrah, you giant, what says the doctor to my water?

Page: He said, sir, the water itself was a good healthy water; but, for the party that owed it, he might have more diseases than he knew for.*

*Shakespeare: 2 Henry IV, I.ii.

Treatment of Bone Tumors in Children

MARK B. COVENTRY, M.D.*

Bone tumors in children present a problem not really different from that in adults. Certain tumors are more prone to occur in childhood and adolescence, and others more likely in later decades of life. The basic treatment, however, remains essentially the same regardless of the age of the patient.

Bone tumors are best considered in three groups: (1) benign tumors, (2) lesions that simulate benign tumors but that are not truly neoplasms, including unicameral bone cyst, aneurysmal bone cyst, fibrous dysplasia, and eosinophilic granuloma, and (3) malignant tumors, classified as accurately as possible according to cell of origin. There are some gray areas in this classification. Is osteoid osteoma truly a neoplasm, for example? The same question might be asked about fibrous cortical defect.

Benign Tumors of Bone

Osteochondroma (Osteocartilaginous Exostosis)

Commonly found at the juxtaepiphyseal area, osteocartilaginous exostosis is frequently multiple and is often familial. It is removed only if it is large enough to produce symptoms because of mechanical and factitial reasons, or if it is becoming disproportionately large. One cannot support the argument that all osteocartilaginous exostoses should be removed because they may occasionally become malignant. These tumors can be followed closely and, if growth occurs, removed. Removal should be adequate, with the base of the exostosis thoroughly excised. Occasionally this will entail use of a bone graft, for some of the bases are quite broad and the bone is weakened when the exostosis is removed.

Chondroma

This tumor is seen most commonly in the hands and feet, and does not become malignant. The chief problem is that of diagnosis. One can be relatively sure of the diagnosis from X-ray evidence alone, as the tumor has a typically clear, lytic, demarcated appearance. Contrary to the behavior of chondromas elsewhere in the body, those in the hands and feet do not seem to manifest an increased incidence of malignancy because of biopsy. If in doubt, a chondroma of the hand or foot can be subjected to biopsy and the site thoroughly excised by curet and bone grafted.

Chondromas elsewhere, in the long bones particularly, are not uncommon and typically contain flecks of calcium. These should not be subjected to biopsy unless they can be treated definitively, and definitive treatment means removing every portion of the tumor. Roentgenographic recognition is not difficult and such a tumor is best left strictly alone unless one can remove it entirely and be prepared to deal with the consequences as far as function of the limb is concerned.

Multiple enchondromatosis (Ollier's disease) presents a similar problem, and individual lesions that do become troublesome must be dealt with accordingly.

Benign Chondroblastoma (Codman's Tumor)

This occurs most commonly at the epiphysis of the long bones and is best treated by excision with curet and bone grafting. Recurrent growth or subsequent malignancy is not a problem.

Chondromyxoid Fibroma

This fairly rare tumor is best treated by excision and bone grafting.

Osteoid Osteoma

Seen commonly in children and adolescents, osteoid osteoma is one of the newer and exciting entities that has captured attention in the last 20 years. Often the diagnosis is obscure and one must exert considerable acumen to demonstrate the lesion roentgenographically after it has been suspected because of the history of pain, specifically relieved by aspirin. The treatment is surgical excision of the nidus. The tumor must be completely removed to assure a cure. Occasionally the defect is large enough to require bone grafting.

Benign Osteoblastoma (Giant Osteoid Osteoma)

This presents a problem in treatment because

*Mayo Clinic and Mayo Foundation, Department of Orthopedics, Rochester, Minnesota.

Requests for reprints address to: Dr. M. B. Coventry, Mayo Clinic, Rochester, Minnesota. 55901.

of its size. It may affect the flat bones of the pelvis or sacrum or the vertebral bodies. Complete excision is sometimes difficult. Some of these tumors, diagnosed by biopsy and not treated, have remained quiescent and stopped growing. Others have continued to grow. They are quite vascular and often difficult to remove. Excision by curettage, when possible, is recommended. Occasionally x-ray therapy also must be given to control growth.

Benign Giant Cell Tumor (Osteoclastoma)

This tumor is rare in the child and adolescent. It is one of the most difficult to treat because of its propensity to recur. All the cells must be removed by one means or another to effect a cure. Because it often affects the lower end of the femur and the upper end of the tibia, which are important weight-bearing structures, radical surgical treatment presents a problem regarding function. Segmental resection, when feasible, is the treatment of choice. When it is not, wide exposure with thorough excisional currettement and irrigation, followed by bone grafting, will often effect a cure. Occasionally one is fortunate enough to find the tumor at a site, such as the upper end of the fibula, that can be resected without sacrifice of function, or in the lower end of the radius, where the entire lower portion of the radius can be removed with the tumor and replaced with a bone graft. Timid inadequate removal of giant cell tumor simply is not effective and results only in recurrence and often, ultimate amputation.

Radiation therapy is to be condemned because of the subsequent change of malignancy.

Fibroma (Fibrous Cortical Defect)

In contrast to giant cell tumor, fibrous cortical defect needs no surgical treatment unless a pathologic fracture occurs. If the bone has been weakened by the cortical fibroma, bone grafting may be necessary, but usually healing occurs with the usual methods of immobilization and use of plaster casts, and no other treatment whatever is required. The important point is to recognize that the fibroma is benign, tends not to grow after full maturity, and will indeed ossify as time goes on. It occurs most commonly about the ankle, proximal to the epiphysis of the distal part of the tibia.

Hemangioma

This tumor may involve large parts of the shaft of large bones or the pelvis, or it may be confined to the vertebral centrum. No really satisfactory treatment is available. Wide excision and bone grafting may occasionally be required. Differences in limb length may occur because of the stimulation of growth by the hemangioma. Even amputation may be necessary at times. A hemangioma in a vertebral body usually needs no treatment and causes no particular disability.

Bone Lesions Simulating Benign Tumors

Solitary Bone Cyst

This is the most common lesion of bone that appears primarily in children. It occurs most often at the upper end of the humerus, but is found at many other sites. It is on the diaphyseal side of the epiphysis and defies easy obliteration, resembling giant cell tumor in its behavior. Surgical excision of the entire cyst and replacement with bone grafts is necessary. Then the patient must be followed carefully for evidence of recurrence. If the cyst does recur, it again must be excised and bone grafting done. There is no place for the use of x-ray therapy in treatment.

Aneurysmal Bone Cyst

A more recently described tumor, this is best treated by curettage and bone grafting of the defect. Such treatment will usually cure the condition, although recurrences are occasionally seen and should be watched for.

Fibrous Dysplasia

Part of a generalized process, fibrous dysplasia is not truly a bone tumor, but acts in this way and is sometimes large enough to weaken the long bone involved by it. It may require excision and bone grafting.

Eosinophilic Granuloma (Histiocytosis X)

This most often affects children—the ribs, skull, and vertebral bodies. When found in a vertebral body, it produces a classic coin-like collapse of the vertebral centrum—"vertebra plana," or Calvé's disease.[1] While formerly managed with x-ray therapy, in recent years there has been some observation that the lesions heal spontaneously. If not symptomatic, therefore, immobilization alone might be tried before irradiation is resorted to.

Malignant Tumors of Bone

Malignant tumors of bone are also best classified by cell of origin, and may be subclassified on the basis of radiosensitivity as follows: radioresistant tumors: osteogenic sarcoma, chondrosarcoma, fibrosarcoma, and malignant giant cell tumor;

radiosensitive tumors: myeloma, malignant lymphoma, and Ewing's tumor; and miscellaneous tumors: chordoma, adamantinoma, angiosarcoma, and liposarcoma.

All malignant tumors of bone affect children except possibly adamantinoma and myeloma. Osteogenic sarcoma, the most common, is of course the classic one of childhood. Primary malignant tumors of bone most often affect young, otherwise healthy individuals in the golden age of youth and development. Amputation, when anatomically possible, is usually preferred for radioresistant malignant tumor of bone, including osteogenic sarcoma, chondrosarcoma, fibrosarcoma, malignant giant cell tumor, and perhaps Ewing's tumor. Statistical evidence indicates that this is the best treatment for these tumors under usual circumstances.[2,3,4]

At what level should amputation be done? Studies at the Mayo Clinic have shown that the tumor extends, on the average, three inches up the medullary cavity beyond the level of cortical involvement that is obvious roentgenographically. So, to get above the tumor, one must leave a fairly wide safety zone, bearing in mind this factor of medullary extension. But there is no added safety in leaving a joint between the tumor and the site of amputation. The amputated specimen is carefully checked by the pathologist to make sure that the entire tumor has been removed grossly and that there is no medullary extension to the amputation site. The point is to remove the tumor completely.

Resection can be considered for certain selective tumors of the extremity. The decision whether to do a wide local resection depends on the degree of malignancy and the anatomic location. Parosteal sarcoma can occasionally be treated by local resection, but recurrence, if such happens, dictates amputation. Chondrosarcoma of low grade and involving a bone that can be resected without severe disturbance in function, such as the upper third of the fibula, can be so treated. Chordoma involving the sacrum is of low-grade malignancy and can be completely removed locally in some instances. Also, in special location such as the thoracic cage, resection is the treatment for radiosensitive tumors, not of choice, but of necessity.

Radiation may be used primarly for radiosensitive tumors or as an adjunct to definitive surgical treatment. Myeloma, especially the solitary type, may be considered a primary malignant tumor of bone for this discussion, though it is not in the same category as the others. It does respond to irradiation, as does malignant lymphoma (reticulum cell sarcoma). Ewing's tumor is relatively radiosensitive and our figures at the Mayo Clinic show approximately the same rate of cure with irradiation as with surgical treatment.[5] Specifically, in the treatment of Ewing's tumor, I believe that if the tumor has not progressed to the point of pathologic fracture or marked soft-tissue involvement, it may be treated by irradiation after the diagnosis has been confirmed by biopsy, and later, if no metastases appear and the tumor regresses, amputation may follow. This is particularly true of tumors of the upper extremity.

Combining irradiation with amputation seems to offer little to the patient unless the amputation has resulted in certain spillage of tumor cells. There then may be some rationale for following amputation with x-ray therapy.

We have not been convinced of the value of preamputation x-ray therapy. Francis[6] recently reported on 33 patients given preliminary x-ray therapy over a period of six to eight days. Amputation promptly followed completion of the irradiation. Seven patients are alive and well five years or more after treatment, giving a survival rate of 21.2%. This rate is similar to ours following surgical treatment alone. Preoperative irradiation delays definitive treatment, and the biopsy itself, performed before treatment is commenced, may be detrimental by enhancing metastasis. Those who advocate this form of therapy would have the patient wait six months or so after irradiation to see whether metastasis occurs and then give definitive surgical therapy if there is x-ray evidence of continued growth of the tumor or if pathologic fracture has occurred. There is as yet no evidence that preamputation x-ray therapy localizes or encapsulates the tumor and prevents metastasis.

The following plan of treatment, and the statistics, from Middlesex Hospital, London, where this method is being employed, is available.[7] Biopsy of the tumor is performed and supervoltage irradiation of the entire limb is begun the same day. The patient is treated five or six days a week for six to eight weeks. Roentgenograms of the chest are made frequently. If there is no

x-ray evidence of metastasis in six months and if there is Xray or other evidence that the tumor is still present, amputation is performed. Amputation may be delayed indefinitely.

Of 109 patients treated at Middlesex Hospital from 1950 to 1962, 26 had sarcoma in Paget's disease, 37 osteogenic sarcoma, 21 fibrosarcoma, and 25 chondrosarcoma. Fifty percent of these patients died of pulmonary metastasis, and in 90% the metastasis was evident one year or less after diagnosis. Surviving among those eligible for five-year follow-up were one of 19 patients with sarcoma in Paget's disease, seven of 30 with osteogenic sarcoma, four of 15 with fibrosarcoma, and seven of 17 with chondrosarcoma. Thus, the five-year survival rate in osteogenic sarcoma was 23%, which is comparable to the rates given in most reports on patients treated by amputation.

Oncolytic chemotherapeutic agents are being developed and used today. As yet there is no proof of their value. A program being conducted at the Mayo Clinic combines the use of actinomycin D with surgical treatment of malignant bone tumors. Statistically the findings are not as yet significant. Our preliminary impression is that this plan has not improved the survival rate. Perfusion is advocated and used palliatively in some centers for malignant bone tumors of the extremity when metastasis has occurred. Again there is as yet no evidence that it is helpful.

Statistics on survival indicate the effectiveness of treatment of primary malignant tumors of bone. Such statistics, to be meaningful, must be based on careful review of a large number of patients.

The survival rates for patients with malignant bone tumors encountered at the Mayo Clinic in the years 1909 through 1958 are given in the Table.

TABLE
Survival Rates for Patients With Malignant Tumors of Bone, Mayo Clinic, 1909 Through 1958

	% surviving	
Type of tumor	5 yr	10 yr
Osteogenic sarcoma	20.3	17.4
Chondrosarcoma		
Operation without entering tumor	76.4	69.2
Tumor cells "spilled"	38.0	18.6
Fibrosarcoma	26.8	...
Malignant giant cell tumor	29.0	...
Malignant lymphoma	34.8	...
Ewing's sarcoma	15.0	10.7
Solitary myeloma	53.0	44.0

Our views regarding treatment may be summarized as follows: Each patient presents a specific problem. Certain generalities can be applied to this patient in view of accumulated experience of ourselves and others. Amputation remains the treatment of choice in patients with primary malignant tumors of bone, which are generally radioresistant. Some respond to irradiation. While irradiation is not generally effective for certain tumors such as osteogenic sarcoma, chondrosarcoma, and fibrosarcoma, it occasionally effects a cure. The amount of irradiation necessary to destroy tumor cells, however, is certainly considerable, and usually results in destruction of the other soft tissues as well. We must give each patient the maximum benefit of surgical treatment as it applies in his individual case and to his particular tumor. We should guard against pessimism and should let large series of cases with adequate follow-up be our guide toward treatment. Although it is difficult to do an amputation because of the obviously deforming results, less radical measures are usually inadequate for radioresistant malignant tumors. A living patient without one of his extremities can be a happy person and a useful member of society.

It has often been said that osteogenic sarcoma is more virulent and more lethal in younger age groups. Hayles, Dahlin, and I[8] attempted to compare the survival rates in osteogenic sarcoma in children less than 16 years of age with the rates in older age groups. We studied the data on children seen in the 50-year period 1909 through 1958;[8] accurate follow-up information was available on 126 of 129. The five-year survival rate for patients less than 16 years of age was 22.2%. In the entire age group, 20.3% survived five years.[4]

Fatal Neoplastic Pulmonary Embolism

During General Anesthesia

WEN Y. YUE, M.D.*

PULMONARY EMBOLISM constitutes one of the most dramatic and tragic events encountered in medical and surgical practice. Although the literature contains numerous descriptions of embolism caused by blood clots, air, fat, and amniotic fluid, tumor embolism occurs rarely. The following report describes a fatal case of pulmonary neoplastic embolism in a young man during general anesthesia and surgery for removal of an abdominal tumor.

Case Report

A 17-year-old male entered the hospital complaining of painful scrotal swelling of one month's duration. His referring physician had prescribed antibiotics without improvement. Examination showed an otherwise healthy young man with a firm tender mass measuring 5 x 6 x 5 cm. in the left scrotum, and a second mass "the size of an orange" in the left upper quadrant of the abdomen.

A left orchidectomy was done without complications; pathological examination of the specimen showed teratocarcinoma with embryonal carcinoma of the testicle. The postoperative course was uneventful. One week later, a lymphangiogram revealed blockage of the left lymphatic drainage, suggesting metastasis. A chest film showed a questionable small nodule in the right lower lung field. A liver and kidney scan appeared normal

A left radical thoraco-abdominal lymphangectomy was attempted one week later with removal of the tenth rib, exposing the left side of the abdomen as well as that half of the diaphragm. Tumor tissue found behind the transverse colon below the spleen and kidney contained the same type of neoplasma as found previously in the testis. Vital signs had been stable; surgical blood loss had been replaced with Ringer's lactate solution and whole blood up to this stage in the procedure.

Quite suddenly, during manipulation and separation of the tumor, the patient's blood pressure dropped precipitously, with slowing of the heart rate as shown by the electrocardiographic monitor. All anesthetics were immediately discontinued, while ventilation with 100 percent oxygen was maintained. Cardiac arrest occurred two or three minutes later. Direct cardiac massage was begun at once and continued for one hour and 50 minutes, accompanied by doses of sodium bicarbonate, isoproterenol, and direct current defibrillation. Following resuscitation, the patient bled profusely and expired 52 hours later.

At autopsy, the pathologist found tumor emboli in the left pulmonary artery and smaller branches of both lungs, fat emboli in both lungs, and a huge left hemi-abdominal hematoma.

Discussion

An embolism may be venous or arterial (pulmonary or systemic) in origin, but a combination of both conditions is possible in patients with atrial or ventricular septal defects. The overall incidence of all types of pulmonary embolus, as revealed in postmortem studies in this country, is about 10 percent.[1] Five cases of massive systemic tumor embolization during or following pneumonectomy have been reported in the literature.[2-5] Taber[4] suggested routine primary pulmonary vein ligation to prevent both macroscopic and microscopic tumor embolization at the time of pulmonary resection for malignancy.

Sudden or unexpected death due to pulmonary neoplastic emboli during or following operation has been reported previously in a total of only six patients.[6-11] Death in four of these occurred during operation; two patients developed pulmonary emboli following surgery. Five of the six patients had renal carcinoma; the sixth had carcinoma of the adrenal cortex. Our patient had teratocarcinoma with embrynal carcinoma of the left testis. Gordon-Taylor and others[12-17] have reported both systemic and pulmonary tumor emboli which appeared during the natural course of disease in unoperated individuals with testicular tumor and sarcomatous malignancy.

Early recognition of pulmonary embolism during anesthesia may be of the utmost importance. The two most prominent clinical signs are a sudden, unexpected drop in blood pressure and irregular breathing during manipulation of the tumor; these symptoms do not correlate with blood

*Chief Anesthesiologist, Veteran Administration Hospital, Minneapolis, Minnesota, 55417.

volume loss or replacement, or change with discontinuation of anesthesia. Respiratory arrest usually occurs promptly, followed by cardiac arrest. Sluggish response to vigorous cardiac resuscitation is also suggestive of pulmonary embolism. Bethune and Brechner[18] indicated that an abrupt fall in alveolar carbon dioxide may be the only sign of early or small-volume venous air embolism preceding the onset of systemic hypotension; they suggest the use of alveolar carbon dioxide monitoring for detection of massive air embolism during surgery. The same measure should aid recognition of any pulmonary embolus.

The coexistence of tumor and fat embolism in this case is another interesting finding. The source of fat could not be identified.

There is no specific effective treatment for pulmonary tumor emboli. If the embolism is massive, nothing short of embolectomy, with or without the use of extracorporeal circulation, would be of value. No one has reported such an application for tumor embolism, however. Supportive measures include the use of hypothermia, administration of steroids, maintenance of blood volume and adequate urinary output, and assisted or controlled ventilation.

Summary

This is a report of a rare case of fatal pulmonary neoplastic embolism occurring in a 17-year-old youth under general anesthesia during removal of a metastatic testicular tumor from the left upper abdomen.

Gastrointestinal Malformations in Down's Syndrome

G. ERIC KNOX, M.D.* and ROBERT W. TEN BENSEL, M.D.†

IT IS THE PURPOSE of this paper to report the five year experience (1963-1968) at the University of Minnesota Hospitals with Down's Syndrome (D.S.) and gastrointestinal malformations.

Case Report

The patient was admitted to University Hospitals at the age of fourteen weeks with a two-week history of vomiting. A diagnosis of D.S. had previously been confirmed by chromosome studies (21 trisomy). Physical examination revealed a "peristaltic wave and olive" that characterizes pyloric stenosis. Fluid and electrolyte balance was achieved in the next twenty-four hours and a Ramstedt pyloroplasty was performed. His postoperative course was uneventful.

Presented, in part, at the Northwestern Pediatric Society, Hudson, Wisconsin on September 26, 1969.

*Currently: Pediatrician, Perinatal Biology, Infant Mortality Branch, National Institute of Child Health and Human Development, Bethesda Maryland. (This work was completed while in his second year of pediatric training at the University of Minnesota Medical School, Department of Pediatrics, Minneapolis, Minnesota)

†Associate Professor, Department of Pediatrics, University of Minnesota Medical School, at Hennepin County General Hospital, Minneapolis, Minnesota.

Reprint requests to: Dr. ten Bensel, Department of Pediatrics, Hennepin County General Hospital, Minneapolis, Minnesota 55415.

The above case revealed little in the literature concerning a possible association between D.S. and pyloric stenosis. No complete review addressing itself to the gastrointestinal abnormalities in Down's Syndrome has been reported.

Review of the Literature

The incidence of D.S. in the general population is 1/600 live births.[1] Table 1 shows the incidence per live births in the general population for the individual gastrointestinal malformations. Data support the premise that duodenal atresia,[12] annular pancreas,[11] and Hirschsprung's disease[16] have an increased incidence in patients with Down's Syndrome. Isolated mention of reports of tracheoesophageal (T.E.) fistulae,[23] pyloric stenosis[1,2] and imperforate anus[1,23] have appeared.

From Carter's study[1] which reviewed 725 D.S. patients and Hanhart's study[19] of 800 D.S. patients, the incidence of gastrointestinal malformations is estimated at 10 to 18%. Carter's figure of 10% is probably more accurate since it is derived from

TABLE 1

Summary of Down's Syndrome and Gastrointestinal Malformations at the University of Minnesota Hospitals 1963-1968:

Incidence: Down's Syndrome occurs 1:600 births. 10-18% have G.I. malformations 1,19. 12% in present series.

G.I. Malformation	Incidence per live births in general population	Incidence of D.S. with Specific Malformation: Literature	Present Series	Incidence of Malformation in Down's Syndrome— Present Series
Imperforate Anus	1/1500-5000[24]	8/198[23]	3/11	3/110
T.E. Fistula	1/1300-4500[24]	2/233[23]	1/16	1/110
Hirschsprung's	1/5000[17]	24/1163[17]	2/13	2/110
Duodenal Atresia/Stenosis	1/10000-40000[24]	150/503[12]	2/6	2/110
Annular Pancreas	1/10000-40000[24]	4-35/100[24]	1/1	1/110
Pyloric Stenosis				
White	1/790[5]	0/329[7a]	3/33	3/110
Black	1/2100[5]	—	—	—
Atrophy-Small Intestine	Not Known (Rare)	—	1/1	1/110
Meckel's	15/1000[24]	—	—	1/110
Duplications	Not Known (Rare)	None Reported	0/10	0/110

autopsy data. No prospective studies for gastrointestinal malformations in D.S. have been reported. Table 2 shows a list of other minor gastrointestinal or genito-urinary malformations which have been described in patients with D.S.

University of Minnesota Hospitals Cases (1963-1968)

Cases seen at the University of Minnesota Hospitals with the diagnosis of D.S. from 1963 through 1968 numbered 110 patients (Tables 1 and 3). Fourteen cases (12%) had GI malformations. T. E. fistulae occurred in one patient and was the only D.S. in 16 patients with T. E. fistulae seen during the same period of time. Three cases of pyloric stenosis occurred in our series of D.S. for an incidence of 2.7% and represented 9% (3/33) of the total pyloric stenosis patients seen during the same period of time. Duodenal atresia occurred in two patients for an incidence of 1.8%. This represents 33% (two of six) of the patients seen with duodenal atresia. Annular pancreas was seen in one patient and represented the only patient seen with this condition during this five year period. One D.S. patient was seen with unremitting chronic diarrhea and malabsorption syndrome, who at autopsy, had atrophy of the small intestinal villi. No similar cases were seen during this five year period. Meckel's diverticulum is a rather common disorder, yet was present only in one patient with D.S. Two patients with D.S. had Hirschsprung's disease and represented 15% (two of 13) of the total patients seen with Hirschsprung's disease. Imperforate anus occurred in three patients and represented three of 11 patients (27%) seen with that condition. Diastasis recti was present in many patients but was not uniformly reported and therefore the incidence could not be determined. Approximately 40% of the present cases had an autopsy examination. Complete evaluation of the autopsy results are not know as some died at home or at another hospital.

Table 3 lists other associated anomalies of interest in the present series: five cases of cataracts; three with chronic persistent diarrhea with no evidence of malabsorption; two patients with lymphoma; one patient with medullary sponge kidney; one with lupus erythematosus; and twelve patients with chronic, persistent infections.

Congenital heart disease was present in 52 patients for an incidence of 47%. This correlates well with Rowe and Uchida's[2] figure of 40%. Fifty-nine percent of the cardiac cases in the present series had an AV canal. The fact that the University of Minnesota acts as a cardiac referral center may account for the slightly higher incidence of congenital heart disease in our series.

Comment

The initial patient who presented with pyloric stenosis is of interest for several reasons. Presentation at fourteen weeks is rare. Only six cases have been reported to develop after three months of age.[4,5,6,7B] None were associated with D.S. Three cases of pyloric stenosis with D.S. have been reported but clinic data related to the time of onset of symptoms is not available on these cases. In our patient, the upper GI series was done to demonstrate any abormal peristalsis and to judge the relative size of the lumen to the olive. The x-ray studies revealed there was decreased motility secondary to decreased force of the peristaltic waves which are normally quite forceful in typical cases of pyloric stenosis. This type of peristalsis has been seen by radiologists at the University of Minnesota Hospitals in children who have developed retardation for many reasons. The decreased force of gastric contractility may very well explain the delayed onset of symptoms in this patient.

TABLE 2
Other Conditions Reported to be Associated With Down's Syndrome

Condition:	Incidence per live birth
Hiatus Hernia[2]	Not Known
Cleft Lip[2]	1/500-1000
Cleft Palate[2]	1/750
Inguinal Hernia[2]	2-13/100
*Umbilical Hernia[2,24]	Depends on Age
Diaphragmatic Hernia[2]	Not Known
Exstrophy of Bladder[2,1]	1/30,000

*Increased incidence in Down's Syndrome reported in all above conditions.[24]

TABLE 3
Patients With Conditions Other Than GI Malformations in 110 Patients

Cataracts	5
Chronic Diarrhea	3
Lymphoma	2
Medullary Sponge Kidney	1
Chronic Infection	12
Lupus	1
Congenital Heart Disease	52
(AV Canal)	30

There has been reported a frequent association of pyloric stenosis in Long Arm "21" Syndrome (antimongolism).[25] Pyloric stenosis has been reported in association with Cerebro-Hepato-Renal Syndrome, Cornelia De Lange Syndrome, Smith-Lemili-Opitz Syndrome and 18 Trisomy Syndrome.[25]

Down's Syndrome (D.S.) and Tracheo-Esophageal Fistula (T.E.)

T. E. fistulae has been mentioned in association with D.S. in eight cases in the English literature.[2,3,23] Little clinical material is available to determine the types of fistulae and the clinical presentation in these cases.

Down's Syndrome and Duodenal Obstruction

In 1939 the association between D.S. and duodenal obstruction was observed.[2] A recent review revealed that 150 of 503 patients with congenital duodenal obstruction had D.S. (29%).[12] The incidence in the literature for duodenal obstruction in D.S. is about 26% [range 18-31%].[8,9,10,11,14,15] The vast majority of the duodenal obstructions in patients with D.S. are of the "intrinsic" variety. This fits well with the concept that in D.S. the bulk of observed pathology occurs because of development that is fundamentally different from normal. The reason for the aberrant development has not been entirely explained.

Patients with D.S. and duodenal obstruction had a significantly higher operative mortality (56%) than did those without D.S. operated on for duodenal obstruction (40%).[10,12]

Down's Syndrome and Hirschsprung's Disease (H.D.)

Hirschsprung's disease and its association with D.S. was first noted by Carter in 1958.[1] Since that time there have been twenty-four cases reported.[17,18] From nine studies of H.D., 2% of the patients with H.D. had associated D.S.[17] This differs from our findings in which 15% of patients with H.D. had associated D.S. In our series, 1.8% of patients with D.S. had H.D. In contrast to the H.D. patient that did not have D.S., the maternal age was advanced in all reported cases with associated D.S.[17]

Down's Syndrome and Imperforate Anus

Carter, in 1958,[1] reported two with D.S. and imperforate anus. Ten other patients are reported with D.S. and imperforate anus.[1,23] The three cases of imperforate anus and D.S. also had congenital heart disease. Recently another case of D.S. and imperforate anus was seen at the University of Minnesota Hospitals. This child did not have congenital heart disease but has a sibling with congenital pulmonic valvular stenosis.

Down's Syndrome and Annular Pancreas

Annular pancreas has an incidence in the general population of one in 10,000 to 40,000 live births.[24] D.S. occurred in 4-35% of these reported cases.[24] One of these cases also had Hirschsprung's disease and intestinal malrotation.[11]

Prognosis

In reviewing all gastrointestinal malformation, it becomes apparent that these are significant as causes of death in D.S., ranking only behind cardiac malformations and infections. They accounted for 8% of the total deaths in our series.

Etiology

It is also apparent that there is a great overlap between the various gastrointestinal malformations, and they often occur simultaneously in the same patient. The commonly cited etiological mechanism is that these malformations are caused either by defective canalization or vascular mechanisms with determination residency on chromosome 21. There is no direct evidence for this interpretation.

Recommendations

Because of the high incidence of gastrointestinal malformations in D.S., these should be carefully looked for in every newborn with this condition. It is recommended that a barium enema and a upper GI series with small bowel follow through be performed on all patients with D.S. The yield of pathology (12%) appears well worth the effort required. Conversely, careful attempts should be made to detect D.S. in all newborns with significant gastrointestinal abnormality since the diagnosis of D.S. is not always readily apparent in the newborn period.

Summary

One hundred and ten cases of D.S. were seen at the University of Minnesota Hospitals for 1963-1968. Fourteen patients had associated gastrointestinal malformations. Pyloric stenosis in association with D.S. has not been previously reported.

References 1-25 will be found on page 579.

Azulfidine Agranulocytosis with Bone Marrow

Megakaryocytosis, Histiocytosis and Plasmacytosis

KHOSROW JAMSHIDI, M.D.,* THOMAS ARLANDER, M.D.,†
MARIO C. GARCIA, M.D.,* HAROLD W. WINDSCHITL, M.D.‡ and
WILLIAM R. SWAIM, M.D.

SALICYLAZOSULFAPYRIDINE *(Azulfidine®)*§ is widely used in the treatment of ulcerative colitis.[1,2,3] Common side effects include headache, nausea, vomiting, epigastric distress, arthralgia, skin eruptions and a mildly elevated temperature. Other reactions such as crystalluria,[1] paresthesia,[4] diarrhea,[5] thyroiditis and tracheolaryngitis with bronchospasm,[6] have been described. Hematologic reactions may include methemoglobinemia, sulfhemoglobinemia,[7,8] cyanosis not related to met- or sulfhemoglobinemias,[1] Heinz body anemia,[8-10] hemolytic anemia[8-11] and jaundice.[12]

Agranulocytosis as a toxic manifestation of this drug, although uncommon, is well established. Thirteen cases with this serious complication have appeared in the literature (Table2).[1,2,12-22] Three additional unpublished cases have been reported to the A.M.A. Registry on Adverse Drug Reactions.£

This paper describes the clinical course and recovery of a patient with Azulfidine® agranulocytosis. Unique cellular changes observed in serial bone marrow examinations are described. Clinical, laboratory and therapeutic findings are compared with other cases in the literature.

Case Report

A 67-year-old white male farmer with dermatomyositis controlled with prednisone (20 mg every other day), was hospitalized for ulcerative colitis. Azulfidine, 1 gram four times a day, was added to the prednisone regimen. This resulted in prompt symptomatic improvement. Hematologic parameters were normal. Four week after discharge and six weeks after starting Azulfidine® he was rehospitalized because of cough, malaise, fever, and roentgenographic evidence of pneumonia. Hematologic studies showed anemia and leukopenia (white blood count, 550/mm³). The differential count was 97% lymphocytes and 3% monocytes. Blood cultures grew out E. coli. Azulfidine® was stopped, prednisone continued and the infection treated with penicillin, streptomycin and kanamycin. (See clinical course Figures 1 and 2.)

Table 1 details the sequential bone marrow changes following discontinuance of Azulfidine®. On the third hospital day the marrow was hypercellular and granulocytic elements were absent. Normoblasts were decreased and plasma cells, lymphocytes, histiocytes and megakaryocytes were strikingly increased. Three units of whole fresh blood were given because of anemia. A marked proliferation of immature granulocytes was present by the 10th day giving the appearance of a maturation arrest. On the 14th day these granulocytes were in various stages of maturity. This was followed by a return of granulocytes and reticulocytes to the blood. Subsequent bone marrows 28 and 115 days later were normal. During the period of agranulocytosis platelets remained slightly increased in numbers in the blood and plasma cells comprised up to 15% of the differential.

Using the leukocyte agglutinin method of Payne,[23] the patients serum on the ninth day contained antibodies which agglutinated leukocytes of two out of 10 normal compatible subjects. Similar studies 17 months later, with or without Azulfidine® in the test system, were negative.

Discussion

Absorption and Distribution

Salicylazosulfapyridine is a poorly absorbed sulfonamide composed of salicylic acid and sulfapyridine linked together by a diazo bond. When taken orally the drug is partially absorbed. A portion is excreted unchanged through the kidneys. The remainder is deposited in the connective tissue of the intestines where it is broken down to aminosalicylic acid and sulfapyridine. Although the mode of action of the drug is unknown, it is assumed that its therapeutic effect takes place in connective tissue.[1-3]

Pathogenesis of Agranulocytosis

The pathogenesis of drug-induced agranulocytosis is not clearly understood. Its low incidence suggests an idiosyncrasy in susceptible individuals. Various possibilities include interference with cellular metabolism, immune mechanisms, and suppression of production or inactivation of hematopoietic factor(s). The latter hypothesis remains a speculation.[33]

Interference with cell metabolism

The first hypothesis has been supported by studies of chlorpromazine-induced agranulocytosis, where interference of cellular metabolism has been demonstrated. In the presence of chlorpromazine, bone marrow incorporation of radio-labeled thymidine and uridine into the granulocytic series is defective.[24,25] These findings are not unique, however, since marrow incubation studies in 75% of random hospital patients also show defective incorporation. Similar studies have not been reported for Azulfidine®.

Immune Reaction

Immune mechanisms for drug related agranulocytosis have been demonstrated for some drugs.[18,26-30] Bone marrow aplasia on an immune

basis has been produced in experimental animals.[32] It has been suspected that certain drugs, including Azulfidine® act as haptens which are capable of combining with leukocyte constituents. This stimulates the production of antibodies directed against these same cells and in some cases the antibodies may react with leukocytes from individuals with compatible ABO and Rh blood factors. The leukocyte agglutinins found in our patient were obtained six days after blood transfusion. Repeat studies 17 months later were negative. There are a variety of possibilities to explain the presence of these weakly positive leukocyte agglutinins. These include: post-transfusion isoantibodies,[34-36] antibodies in transfused blood, and antibodies related to the patients collagen disease[37] and/or Azulfidine®.[18]

Blood, Bone Marrow and Leukemoid Reactions

The usual picture of a drug-induced agranulocytosis in its early stages is that of leukopenia with a hypocellular or, less commonly, a normocellular bone marow. Coupled with the leukopenia is an absolute reduction in numbers of granulocytes, monocytes and lymphocytes. The differential blood count shows a relative lymphocytosis, often 100%. Marrow elements are predominantly lymphocytes. The granulocytic series is markedly decreased or absent. The erythroid element of the marrow is slightly to moderately decreased, but may appear normal or increased because of the paucity of other cellular elements. Megakaryocytes are usually decreased and plasma cells are normal or decreased.

In contrast, the unusual hypercellularity of the bone marrow in our patient (Table 1) was due to marked increases in histiocytes, megakaryocytes, and plasma cells. The return of granulocytic cells to the bone marrow was followed by an intense neutrophilic leukocytosis and a marked absolute monocytosis in the blood. Leukocytosis in the recovery phase of drug induced agranulocytosis may be so intense, as it was in this case, that a leukemoid or leukoerythroblastotic picture is seen. This type of response, in addition to hyperplasia of granulocytic marrow elements, may be misinterpreted as a myeloproliferative disorder, leukemia,[38] or maturation arrest. With observation it will be appreciated that such patterns represent different periods of marrow recovery.[25]

Two additional unusual findings in this case were a peak lymphocytosis in the blood, which followed those of neutrophils and monocytes, and a plasmacytosis (15%). The lymphocyte pattern confirms Nja's observations in a case of Azulfidine® agranulocytosis. This is in contrast to the cell recovery pattern for chlorpromazine agranulocytosis.[25] The reason and significance of the delay in peak lymphocytosis is unclear. The plasmacytosis suggests the possibility that alterations in immune mechanisms may have occurred in this patient.

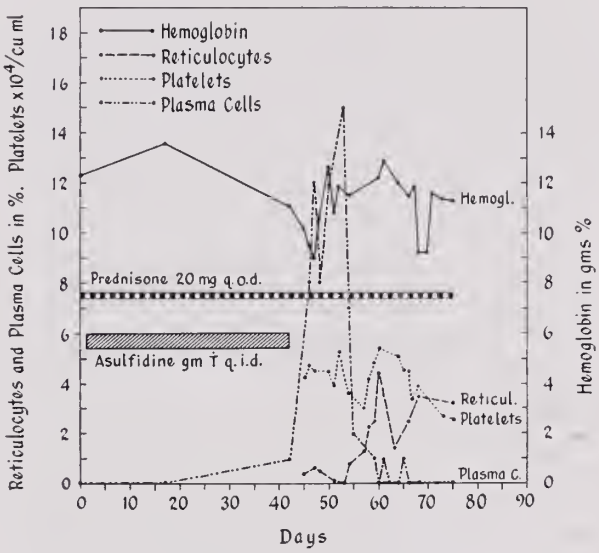

Fig. 1—Clinical Course—Hematology Data.

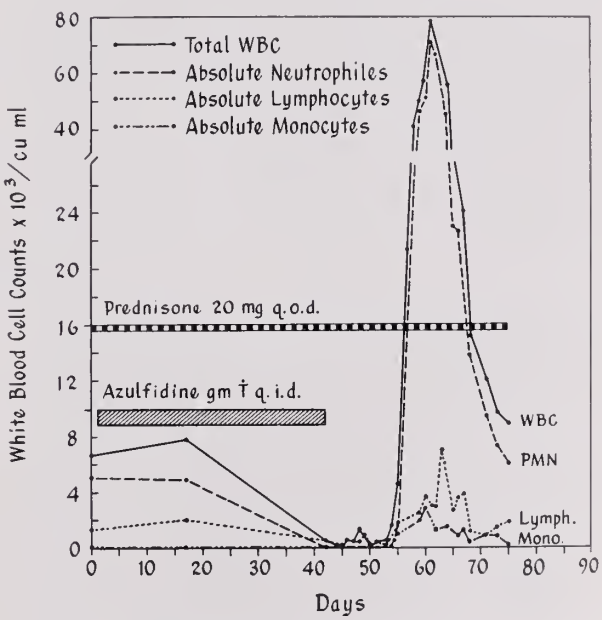

Fig. 2—Clinical Course—Hematology Data.

The increased numbers of histiocytes in the marrow may be the result of stimuli to clear the marrow of damaged cells. However, the increased numbers of megakaryocytes in the marrow, in addition to the histiocytosis, appears to be unique. No other reported case of Azulfidine® agranulocytosis showed similar features (Table 2.)[1,2,12-22] Additional sequential studies of blood and bone marrow in other cases will be needed in order to assess the significance of these findings.

Recognition and Therapy

Patients receiving drugs potentially toxic to the bone marrow should have regular blood studies including blood smear examinations and white blood counts. Fortunately, Azulfidine® agranulocytosis appears to be infrequent. In the event of fever, rash, "colds", sore throat or any unusual symptomatology patients should be instructed to stop drugs immediately, and contact their physician. If the blood and bone marrow findings are similar to those previously described, Azulfidine® should be discontinued and therapy directed toward combating infection.

Steroid Therapy

The use of corticosteroids in addition to antibiotics and blood transfusions, has been advocated by some,[39,41] however, this is controversial.[31,42] Our patient, Koskinen's, Ritz's and two of the three unpublished cases reported to the A.M.A. Registry on Adverse Drug Reactions received corticosteroids and all recovered. Only six of the remaining 12 patients (Table 2) who were not on sytemic corticosteroids recovered. This data does not establish the role of steroids in treating such patients, but it does emphasize the need for further information. Other types of steroids, such as anabolic steroids, have been effective in some types of drug-induced bone marrow aplasia.[45,46] None of the reported cases of Azulfidine® agranulocytosis have been treated with this class of steroids.

Antibiotics

Antibiotics play an important role in increasing survival. In the pre-antibiotic era the mortality of drug-induced agranulcytosis was as high as 80%.[41] Despite appropriate supportive measures and the use of appropriate antibiotics, mortality still remains high (5 to 50%).[41,43,44]

Summary

The course of a patient with Azulfidine®-induced agranulocytosis is described. Serial bone marrow studies during the period of agranulocytosis and recovery phase showed the unusual findings of hypercellularity with a marked increase in megakaryocytes, histiocytes and plasmacytes. The circulating blood showed plasmacytosis. This combination of blood and marrow findings have not been previously described. Upon recovery, the bone marrow and circulating blood were completely normal. Steroids may have contributed to the patient's survival. All patients reported (5), including the present case, who received steroids recovered.

Acute Acalculous Cholecystitis

RICHARD J. HOWARD, M.D.* and JOHN P. DELANEY, M.D., Ph.D*

Cholelithiasis is found in 90 to 95 per cent of patients with acute cholecystitis and is believed to be a major etiologic factor. Little attention, however, has been directed to those cases where acute cholecystitis occurs in the absence of stones. We review here all cases of acute acalculous cholecystitis occurring at the University of Minnesota and allied hospitals during a 16-year period 1954 through 1969.

Chart Review

In the years 1954 through 1969 780 patients underwent cholecystectomy for acute cholecystitis at the University of Minnesota Hospitals and affiliated teaching hospitals. In each instance the diagnosis was confirmed by pathologic examination. No calculi were found in 34 (4.4 per cent) specimens. The patients' ages ranged from 18 to 87 years (average 57).

Medical History

Only four patients had symptoms suggestive of gallbladder disease, fatty food intolerance. Eight patients developed acute acalculous cholecystitis while recovering from operative procedures, only two of which were intra-abdominal. Four others had suffered extensive trauma in automobile accidents, and two of these had operations related to the injuries.

Four other patients were alcoholics, and one of these developed cholecystitis while being treated for bleeding esophageal varices. Nine patients had been treated for cancer including lung, stomach, prostate, thyroid, cervix, breast and testis. Other associated medical problems included ulcerative colitis, heart disease, arteriosclerotic peripheral vascular disease, and gastric ulcer.

Symptoms and Signs

Right upper quadrant pain was the most common complaint, noted in 26 of the 34 case records. In two the pain was diffuse throughout the abdomen and in one it was periumbilical. Three patients had no pain and one patient was comatose.

Right upper quadrant tenderness was detected in 28 patients. Two had diffuse abdominal tenderness and three had none. Twenty-two patients vomited. Six of the 34 had a palpable right upper quadrant mass. Abdominal distension was present in 12, bowel sounds were decreased or absent in 14, and clinical jaundice was detected in seven instances. Twenty-seven patients had fever.

Laboratory Studies

The white blood cell count ranged from 4750 to 29,000 cell per cu mm, exceeding 10,000 in 23 instances. The serum bilirubin was measured in 25 patients and was elevated in 12, exceeding 3 mg/100 ml in seven. The serum glutamic oxalic transaminase was elevated in six of 10 measurements, and the alkaline phosphatase was increased in eight of 18 patients.

Roentgenographic Studies

Biliary x-ray studies were done in 12 patients. The gallbladder did not visualize in 11 examinations. Air was seen in the gallbladder lumen in one.

Preoperative Diagnosis and Operation Performed

There was a delay of one to 67 days from the onset of symptoms to operation. Acute cholecystitis was not suspected in 12 instances. Incorrect diagnoses included subhepatic abscess, hepatic abscess acute appendicitis, "inflammatory mass", ruptured spleen, and mesenteric vein thrombosis.

Cholecystectomy was performed in all cases, although cholecystostomy was done initially in three instances because inflammatory reaction obscured the anatomy. Elective cholecystectomy was performed one to two months later. Common bile duct exploration was carried out in four patients because of jaundice. Common duct

*Department of Surgery, University of Minnesota Hospitals, Minneapolis, Minnesota.
Reprints requests mail to: Dr. J. P. Delaney, Box 89, Department of Surgery, University of Minnesota Hospitals, Minneapolis, Minnesota 55455.

exploration was not performed in three jaundiced patients, one of whom had a normal operative cholangiogram.

Pathology and Bacteriology

Acute cholecystitis was confirmed histologically in all cases of acalculous cholecystitis. The gallbladder wall showed areas of gangrene in 14 specimens. There were three instances of empyema and three of localized perforation.

The bile was cultured from 17 patients and the surrounding peritoneal fluid from eight. Eight of the 25 specimens were sterile. *Escherichia coli,* the most common organism, was cultured eight times. Other organisms included alpha hemolytic streptococcus, coagulase negative staphylococcus, klebsiella, aerobacter, pseudomonas, clostridium, and bacteroides. In three instances the organism found in the bile had previously been cultured from the blood. One patient had a urinary tract infection caused by the same organism found in the bile.

Morbidity and Mortality

There were seven deaths. Two occurred in patients who had been involved in automobile accidents and had extensive injuries. Cholecystitis developed five and 35 days after injury. A 20-year old man was brought to the University of Minnesota Hospitals five days after treatment in another hospital for injuries sustained in an automobile accident. He was comatose and was operated upon because blood was found in the peritoneal aspirate. He died in the early postoperative period with pneumothorax and adrenal hemorrhage. A 66-year old woman died of congestive heart failure one month following cholecystectomy, vagotomy and gastrectomy.

Three deaths occurred in patients who developed acute cholecystitis while recovering from other surgical procedures. A 63-year old man who had the onset of symptoms 20 days after insertion of an aortic valve prosthesis died of cardiac arrest shortly after cholecystectomy. A 79-year old woman developed pneumonia after radium insertion for carcinoma of the cervix. She developed cholecystitis 27 days later and died of continuing pneumonia and septicemia one month following cholecystectomy. The third patient was a 73-year old man who had gram negative sepsis and cholecystitis following thyroidectomy and radiation for lymphoblastoma of the thyroid. A bleeding dyscrasia developed after cholecystectomy, and death resulted from gram negative sepsis.

Two other patients, both alcoholic, also succumbed. One had cholecystectomy for acute cholecystitis discovered during emergency portacaval shunt. He died 15 days postoperatively of recurrent upper gastrointestinal hemorrhage and hepatic coma. An 85-year old male developed congestive heart failure following cholecystectomy and died.

Three non-fatal complications related to cholecystectomy. Two patients had prolonged bile drainage which ceased spontaneously. A 78-year old man developed hepatitis six months following cholecystectomy, was treated medically and recovered.

Incidence

In large series of acute cholecystitis 90 to 95 per cent of the patients have gallbladder stones and two-thirds are women.[2,6,8] Conversely, three-fourths of the patients with acalculous cholecystitis are male. In the present series also, when six male patients from the Veterans Administration Hospital are excluded, 71 per cent of the patients were male. The incidence of the acalculous variant is significantly higher when cholecystitis occurs in the postoperative period [10,12], after trauma[11], or in children.[3,7]

Pathogenesis

Experimental work indicates that bile stasis, impairment of blood supply, and cystic duct obstruction are the most important factors in the development of acute cholecystitis.[13]

Infection has also been proposed as a cause of cholecystitis. Lindberg et al.[11] found infected bile in nine of 12 wounded soldiers with acute acalculous cholecystitis. Six of the nine had wounds infected by the same organism subsequently found in the bile. Cole et al.[4] have proposed that infection is a late event imposed upon an already inflammed gallbladder. A lower incidence of positive cultures of bile and gallbladder wall is found if the specimen is obtained in the early, rather than late, phase of acute cholecystitis.[1,8]

Reflux of pancreatic secretions into the gallbladder has also been implicated in the etiology of cholecystitis. Colp et al[5] found amylase and trypsin in the bile of inflammed gallbladders and Wolfer[14] produced cholecystitis by injecting

pancreatic juice into the gallbladder of dogs.

Clearly, no single explanation can account for all cases of acute acalculous cholecystitis. Most of our patients were being treated for other illnesses at the time of onset of acute cholecystitis. Eight developed cholecystitis while recovering from operations and four following extensive injuries. Several previous reports have implicated surgery and trauma as predisposing to acute acalculous cholecystitis.[10-12]

Many of our patients had arteriosclerosis. Their gallbladder blood flow may have been decreased to a level where further minor insults could lead to cholecystitis. No cystic duct obstruction was evident in these patients.

Summary

Thirty-three patients developed acute cholecystitis without gallbladder stones. There were 25 males and eight females. Three-fourths were older than 50 years. Only four patients had prior symptoms referable to the biliary tract. Eight developed acute cholecystitis while recovering from surgery, and four had suffered extensive trauma.

Their symptoms did not differ appreciably from patients with acute acalculous cholecystitis. Right upper pain and tenderness, vomiting, abdominal distention, decreased bowel sounds, jaundice, and fever were frequent.

Fourteen specimens showed gangrene. There were three instances of empyema and three of localized perforation. Seventeen of 25 specimens were infected; *E. coli* was the most common organism.

We believe that decreased gallbladder perfusion caused by arteriosclerosis possibly combined with a low cardiac output contributed to the development of cholecystitis. It is not clear if cystic duct occlusion was a factor.

Anorexia Nervosa

94-Year-Old Woman Treated with Electroshock

IRVING C. BERNSTEIN, M.D.*

ANOREXIA NERVOSA is a serious nervous condition in which the patient loses his appetite and systematically takes but little food, so that he becomes greatly emaciated."[1] When this illness endangers life, treatment modalities should be utilized which are effective in the shortest period of time.

Electroshock should be used to treat the affective components of severe psychiatric illnesses, whether they be neurotic depressions, psychotic depressions, schizophrenic reactions, or manic depressive reactions. It is also effective for psychoneurotic symptoms such as pain and anorexia which are indicative of severe affective states.[2] Anorexia Nervosa in young women has been treated successfully with electroshock,[3] but its use need not be limited to youthful patients with this illness.

*Clinical Professor of Psychiatry, and Obstetrics and Gynecology at the University of Minnesota, and Chief of Psychiatry at Mount Sinai Hospital in Minneapolis.

Case Report

A 94-year-old widow was admitted to Mount Sinai Hospital on May 22, 1971 after she had fallen to the floor and sustained an injury to her left hip. The orthopedist who saw her diagnosed her as "mentally disturbed and having a fracture in the intertrochanteric area of the left femur." This fracture was successfully operated upon on May 26, 1971. On May 27, 1971 she refused to eat and was noted to be uncooperative, agitated, depressed, and paranoid. This refusal to take anything by mouth continued, and she became progressively weaker. The doctors and hospital personnel involved in caring for her became concerned because she was obviously going to

Figure—Ninety-four-year-old widow treated for anorexia nervosa. (Permission given by daughter to use picture.)

starve herself to death.

Her only living relative, a daughter, was extremely distraught, especially about her mother's not eating, and had ambivalent feelings about permitting her mother to die. She said: "Mother has tried to control me all my life by making me feel guilty about not taking care of her, but she did get me out of Russia after World War I. Still, she's been sick so long she might as well die."

The patient's condition continued to deteriorate and on June 8, 1971 a psychiatrist was called in for consultation. He commented: "This lady has been schizophrenic for years, is now almost catatonic, and should be treated with electroshock immediately." With much reluctance, the daughter gave permission for electroshock therapy. Her attending physicians were not enthusiastic about this recommendation and decided to institute intravenous feedings instead. The patient's weight at this time was 80 pounds. With this conservative management, the patient's hydration improved somewhat, but she continued to starve herself. She was completely uncooperative and rebellious. Finally, on June 21, 1971, her doctors agreed the patient would not improve on conservative management and consented to the administration of electroshock. The first treatment was given the same day. After the second treatment on June 23, the patient began to eat and her general condition and attitude began to improve. Electroshock was discontinued after the fifth treatment on June 30, only nine days after it had been instituted, because of the patient's dramatic improvement, including a weight gain of six pounds. She was very cooperative, ate well, and showed almost no paranoid thinking. At this time, her daughter stated the patient was better than she had been for over 50 years and remarked sorrowfully that electroshock had been considered for her mother's schizophrenia 15 years earlier, but was not given because "the patient is too old." The patient continued to improve and was discharged to a home for the aged on July 12, 1971, when a bed first became available.

Discussion

This patient, despite her age, can be considered a case of anorexia nervosa. She demonstrated the typical psychodynamics that Frazier[4] describes. "These emaciated patients suffering from lack of affection and severe emotional isolation utilize the pursuit of thinness as a weapon in the struggle for control of family members." In addition, this case corroborates Kalinowsky's statement[5] that electroshock is more effective than neuroleptic drugs in many schizophrenic syndromes.

Summary

A case of anorexia nervosa has been presented to demonstrate the effectiveness of electroshock therapy in this entity and to emphasize that advanced age is no contraindication for its use.

Cover Photograph

"Tumbler Landscape"

The cover photo was taken two years ago by Dr. Donald C. Bell, internist, at Snowmass, Colorado. He and his family were at lunch and the empty tumbler on the table cast this unusual reflection. Dr. Bell thought this would create an interesting picture and took the cover photograph.

Dr. Bell practices at the Fairview Hospital and the Metropolitan Medical Center in Minneapolis, Minnesota.

Meeting

The 32nd Annual AMA Congress on Occupational Health will be held at The Drake Hotel in Chicago, September 11-12, 1972. Contact Dr. Henry F. Howe, AMA, 535 North Dearborn Street, Chicago for further information and reservations.

Case Report-

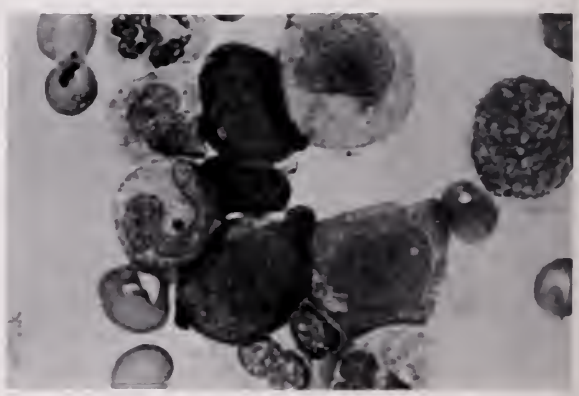
Megaloblastic Anemia and Oral Contraceptives

W. M. SALTER, M.D.*

ORAL CONTRACEPTIVES have become implicated in an ever increasing number of serious side effects.[1-3] Streiff[4] reported seven cases of megaloblastic anemia associated with the use of oral contraceptive agents. Others have similarly associated the use of oral contraceptive and folate deficiency.[5] This report concerns a severe megaloblastic anemia apparently due to long term cyclic administration of an oral contraceptive.

Case Report

A 47-year-old white female was hospitalized for weakness, lethargy and dyspnea on exertion progressively and gradually more severe over a four month interval. She had six previous pregnancies, the youngest child five years of age. She denied weight loss, sweats, fever or chills and had no diarrhea, change in character of stools, nausea or vomiting. Specifically she denied symptoms suggesting malabsorption problems, i.e. frothy foul stools fatty or oily appearing bowel movements. There was no numbness, tingling of hands or feet and no complaint of sore tongue. She had a past history of probable discoid lupus some fifteen years earlier. The patient's medications were only Ovulen-21 (ethynodioldiacetate and mestranol) and intermittent diuril (chlorothiazide) for mild dependent edema. She had taken Ovulen-21 on a 20-day cycle, five days off, continuously for over four years. She had no other past illnesses. Her diet had been well balanced with no peculiar dietary habits.



Physical examination found a pale-appearing but well nourished female. Her weight was 116 pounds. The tongue was pale and smooth. A grade 2/6 stystolic murmur was present at the left sternal border of the heart. The blood pressure was 120/76. The abdomen was normal. The liver and spleen were not palpable. There were no masses. The pelvic and rectal exams were also normal. There were small purpuric areas over both forearms and trace of edema of both lower legs. The reflexes were active and equal. The vibratory and position sense were intact. Coordination and muscle strength were also normal.

Laboratory Findings

Initial hemoglobin was 4.7 gm%, hematocrit 14%. RBC 1.4 million per cmm. The mean corpuscular volume was 147 cubic micra. The white blood count was 4,700 with 75% segmented neutrophils, 1% stabs, 23% lymphocytes and 1% eosinophils. The platelet count was 98,000. The peripheral blood smear showed prominent macrocytosis with some ovalocytes but only a mild anisopoikilocytosis. There were numerous hypersegmented neutrophils. A bone marrow aspiration revealed a myeloid erythroid ratio of 2:1 with erythropoiesis being megaloblastic (see Figure). Giant and hypersegmented neutrophils were present. The reticulocyte percentage was 0.2%. A serum iron was 270 micro gm% and the iron binding capacity 270 micro gm%. A gastric analysis revealed 55 millequivalents of free acid after 50 mgs. of histalog intramuscularly. The transaminase was 54 units, the lactic dehydrogenase 4700 units, and the serum bilirubin was 0.3 mg% total and 0.15 mg% direct. The total protein was 5.0 gm% with 3.4 gm% albumin. The BUN was 8 mg%, the cholesterol 145 mg%, and the alkaline phosphatase 53 international units. The fluorescent antinuclear antibody and L.E. preps were negative. A protein bound iodine was 6.4 mcg%. An eight-hour plasma B-12 absorption was calculated at 0.316% with normal values being greater than 0.2% absorption of administered dose of radioactive B-12. The serum B-12 was 140 picograms per ml‡ and serum folate was under 2 millimicrograms per ml†. The normal value of serum B-12 for females is 90-630 picograms and for folate, 5-21 millimicrograms per ml. A chest Xray and an upper GI with small bowel follow through studies were normal.

Hospital Course

Following completion of laboratory studies the patient was given 2 units of packed cells which brought the hemoglobin level to 8.4 gm%. The Ovulen-21 was withheld and folic acid 5 milligrams daily administered. Ten days following daily administration of folic acid

Figure—Bone Marrow Aspiration. Note megaloblastic changes and giant neutrophils.

the hemoglobin was 9.3 gm% and the reticulocyte count 4.0%. On the 16th day after beginning folic acid therapy the hemoglobin was 10.9 gm%, the hematocrit 32%, the white blood count 9,250 and the platelet count 451,000. Four weeks after initiating therapy the hemoglobin rose to 13.9 gm% and hematocrit 41%.

Comment

The diagnosis and management of megaloblastic anemias, formerly a straightforward problem, has been complicated in recent years with the use of diverse drugs singly and in combination. It is known that hydantoin derivatives and some barbituates may interfere in folate absorption and p-aminosalicylic acid and colchicine with B-12 absorption.[6,7] Streiff[4] recently described seven women with folate deficiency and anemia with no explanation other than the fact that all were taking oral contraceptives regularly for at least 1½ years. In his studies Streiff noted that oral contraceptives blocked the absorption of dietary folate (polyglutamic folate) but not folic acid as found in vitamin preparations (monoglutamic folate). He noted that polyglutamic folate must undergo enzymatic change before absorption takes place. Results on 18 normal female volunteers demonstrated that oral contraceptives caused a mean reduction in food folate absorption by approximately 50%. In view of such findings the rarity of anemia is not well explained except to say that the usual American diet contains considerably more folate than the minimum required by an adult. Also, restoration of folate levels may occur in most women during the five day cycle free of taking these drugs.[4] It should be pointed out that it is not necessary to discontinue oral contraceptives when they are implicated as the cause of megaloblastic anemia but folic acid supplementation is necessary.

Minnesota Medicine Cover Award, 1971

Louis A. Buie, Sr., M.D.

Sir Winston Churchill took up painting at age 40. Dr. Louis Buie, of the Emeritus Staff of the Mayo Foundation, waited until he was well past 70, and started then only because, during an illness, "my wife encouraged me to try." So energetically did he follow her advice that the Buie recreation room turned studio now hardly holds all his canvases. "I could always sketch." This talent is evident in charcoal heads of persons for whom he has high regard. With oils he paints "things I remember," and his memory is long, extending back to scenes of his South Carolina youth.

Dr. Buie is a world-famous proctologist and one of the first in his specialty. He practiced with the Mayo Brothers in Rochester.

The April, 1971, issue of MINNESOTA MEDICINE on which Dr. Louis A. Buie's painting "South Carolina, Remembered" is featured has been selected as the outstanding cover for 1971.

Letter to the Editor

Dear Editor:

This communication is prompted by my encountering an infant of seven months at a Crippled Children's Clinic on April 5th whose mother had been told by a Minnesota physician to begin the elimination of milk from her child's diet because it was bad for babies and children. The physician may have been misquoted, on the other hand, the mother was reducing the infant's milk under that understanding.

There seemed to be three reasons why the milk might be eliminated from the child's diet. The first is an allergic one which this child did not have. The second is an intolerance due to low lactose intolerance which this child did not seem to have either. Finally, the possibility that the fats of milk contribute ultimately to coronary problems. Since milk forms the essential part of an infant's diet throughout the first year at least, it would seem that eliminating it on this basis at the age of six months might be detrimental to the child's health. Ultimately, we may find that American children are given milk for too long a period of time and perhaps in too large quantities. At the present time despite the recent pronouncements about this by some in the field of cardiology, I question that the evidence is sufficiently sound to warrant tampering with the milk intake of infants below the age of one year. I refer your readers to a statement* put out by the Protein Advisory Group of the United Nations System concerning lactose intolerance. This Protein Advisory Group is made up of some very knowledgeable people in the field of childhood nutrition from all over the world. It is headed by Professor Bo Vahlquist who is director of the Department of Pediatrics in Uppsala, Sweden.

G. B. Logan, M.D.†
Rochester, Minnesota

*Copies may be obtained without charge from the Protein Advisory Group of the United Nations System, United Nations, New York 10017, U.S.A.

†Pediatrics, Allergy and Clinical Immunology, Mayo Clinic.

Dear Editor:

This is an addition to the letter that I wrote to you a short time ago regarding an apparent misunderstanding by at least one doctor and perhaps others in Minnesota about the need to restrict milk intake in babies. The initial letter concerned only lactose intolerance.

I should have included references to two articles in the February issue of *Pediatrics* for 1972. These articles concern the relationship between milk ingestion and atherosclerosis which is the concern of some cardiologists.

The first of the articles is a report from the Subcommittee on Atherosclerosis Council of Rheumatic Fever and Congenital Heart Disease of the American Heart Association. The second is a report of the Committee on Nutrition of the American Academy of Pediatrics. I will add only one quote from the latter report which summarizes the recommendation at the present time: "The Committee stresses that such dietary intervention is at present experimental and recommends against dietary changes for all children". The Academy of Pediatric Committee on Nutrition goes on to state that dietary intervention may be warranted in special circumstances but not before the children are one year of age.

George B. Logan, M.D.

PROTEIN CONTENT / 1 Cup Prepared Soup*

Bean with Bacon	7.7	Green Pea	7.8
Beef	9.1	Hot Dog Bean	8.6
Chicken Broth	8.4	Oyster Stew	6.0
Chicken 'N Dumplings	6.6	Pepper Pot	6.9
Chili Beef	7.0	Split Pea with Ham	11.6
Consomme	5.6	Vegetable Beef	5.7

When protein is the focal point in your patients' special diets, Campbell's Soups can be a convenient supplementary source of that essential nutrient.

* From "Nutritive Composition of Campbell's Products" which gives values of important nutritive constituents of all Campbell's Products. For your copy, write to Campbell Soup Company, Dept. 365, Camden, New Jersey 08101.

There's a soup for almost every patient and diet ..for every meal and, it's made by Campbell

the 3 phases of Eve

All women are not equal in their endogenous hormonal output. And, while all oral contraceptives are fundamentally effective, they exhibit **differences in their activity levels and estrogen-progestogen ratios that affect different women differently**—in both short and long-term use. Some brands may be insufficient for the woman's needs or else may exceed them.

Searle offers a family of O.C. products that covers the range of women's needs to help you provide the right pill for the right woman at the right time.

the Ovulen phase

Most women* with a **balanced hormone profile** a **normal menses** do best on a middle-of-the-road p that is neither estrogen dominant nor strongly progestogen dominant.

(*Typical clues—normal body build and breasts feminine appearance, healthy skin and hair. Vagin cytology slide—balanced "pink and blue.")

Some women having problems on other O.C.s might do well on Ovulen.

Ovulen has a distinctive hormonal balance that combines moderate estrogenic activity with a sli progestogen dominance. It has an excellent recor of patient acceptance.

Ovulen®

Each white tablet contains: ethynodiol diacetate 1 mg / mestranol 0.1 mg

SEARLE

For brief summary of prescribing information, see following page.

the Demulen phase

Many women* who secrete **more estrogen** than most do well on a pill with lower estrogen activity and an increased progestogen overbalance.

(*Typical clues—shorter, plumper, full-breasted, with glowing skin and no wrinkles. Vaginal cytology slide "pink.")

Some women with special conditions that may be aggravated by higher estrogen-activity products may do better on this ratio.

Demulen combines minimal estrogenic activity with a moderate ratio of progestogen overbalance. It is particularly well suited to the young when low-dose (activity) is preferred. Demulen offers little risk of the most potent progestogen side effects; early breakthrough bleeding is often transient.

Demulen®

Each white tablet contains ethynodiol diacetate 1 mg / ethinyl estradiol 50 mcg
Each pink tablet in Ovulen-28* and Demulen*-28 is a placebo, containing no active ingredients
Both Ovulen and Demulen are available in 21- and 28-pill schedules

the Enovid-E phase

Some women* who secrete **less estrogen** than most do best on a pill with a moderate estrogen overbalance.

(*Typical clues—oily complexion, acne, hirsutism, masculinity, flat chest. Vaginal cytology slide—"blue.")

Patients with estrogen deficiency may show:

premenopausal syndrome
early-cycle bleeding
scanty menses
intermittent depression
increased appetite
steady weight gain
vaginal candidiasis

Enovid-E not only provides increased estrogenic activity with low progestogen activity, but also contains the only progestogen that is not antiestrogenic. Therefore it offers less risk of high-dose progestogen side effects.

Enovid-E®

Each tablet contains: norethynodrel 2.5 mg / mestranol 0.1 mg

Oral contraceptives are complex medications and, after reference to the prescribing information, should be prescribed with discriminating care.

for the 3 phases of Eve:

a family of O.C. products

Ovulen®

Each white tablet contains:
ethynodiol diacetate 1 mg., mestranol 0.1 mg.

Demulen®

Each white tablet contains:
ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.

Each pink tablet in Ovulen-28® and Demulen®-28 is a placebo, containing no active ingredients.

Actions—Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note—Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication—Ovulen and Demulen are indicated for oral contraception.

Contraindications—Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings—The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain[1-3] leading to this conclusion, and one[4] in this country. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll[3] was about sevenfold, while Sartwell and associates[4] in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as nonusers. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations preexisting uterine fibromyomas may increase in size. Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. Any possible influence of prolonged Ovulen or Demulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Ovulen or Demulen therapy. The age of the patient constitutes no absolute limiting factor, although treatment with Ovulen or Demulen may mask the onset of the climacteric. The pathologist should be advised of Ovulen or Demulen therapy when relevant specimens are submitted. Susceptible women may experience an increase in blood pressure following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives—A statistically significant association has been demonstrated between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals and mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function: increased sulfobromophthalein retention and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine and decrease in T^3 uptake values; metyrapone test and pregnanediol determination.

Medical Writing Awards: 1971

"Who can confidently say what ignites a certain combination of words, causing them to explode in the mind?" E. B. White, Elements of Style

Who indeed?

Certainly not I.

Nevertheless I shall try to guess why the Board of Editors picked the following three articles as the best published in MINNESOTA MEDICINE in 1971:

Bring Back the Mustard Plaster, December, 1971, Seymour Handler, North Memorial Hospital, Minneapolis.

Splenic Rupture: A Review of 114 Cases, March, 1971, Dean B. Pratt, Robert C. Andersen, and Claude R. Hitchcock, Hennepin County General Hospital, Minneapolis.

A Physician by the Name of Ohiyesa, July, 1971, Thomas W. Milroy, Student Health Service, University of Minnesota, Minneapolis.

Why did the Board blow their minds over these three?

No one can say for sure.

Titles

But I think the three titles had a great deal to do with winning.

Take, for example, "Bring Back the Mustard Plaster." Now there's a title with flair. And mystery. It's got enough of both to lure the reader to find out who's plastering whom.

At first blush, you might not consider "Splenic Rupture: A Review of 114 Cases" as a title with much clout. You'd be wrong. It has clout for a couple of reasons—some obvious, others not so obvious.

In the first place, 114 cases with ruptured spleens are a lot of cases. The reader can only surmise that these authors must know what they're 'alking about. This is obvious enough. What's not so obvious is the importance of the authors' credentials and the readers' natural interest.

When you read a title, you consider the source. Hennepin County General Hospital has a national reputation for treating domestic casualties. This then is an article you must respect. Besides, ruptured spleens is a subject that would naturally interest many practicing physicians. After all, anytime the physician treats an accident victim with abdominal injuries, the thought of a bleeding gaping spleen flits through his mind.

Why "A Physician by the Name of Ohiyesa" has appeal is hard to explain. But the appeal is there. It's mostly an esthetic matter. The title just has lyrical charm—the right ring. Perhaps it's the Indian name of "Ohiyesa." Somehow that stirs the soul.

Something to Say

There's more, of course, to writing an award winner than picking a title.

In fact, there are three things, the title being one of them. John Shaw Billings (1838-1913), a physician who started the *Index Medicus,* defines these three as well as anyone:

> "First have something to say,
> 2nd say it, and
> finally give it an accurate title."

All of our winners had something to say.

Handler, a pathologist, said this:

> "If a physician must do something—or the patient feels he must do something—consider a mustard plaster. The patient will know something is being done. It will keep him busy while nature effects a cure."

Humor has its place, and Handler has used it well to say what we sometimes need to be reminded of.

Another man in another time, this one a clinician, said it this way:

> "It is a great mistake to suppose that Nature always stands in need of the assistance of Art . . . nor do I think it below me to acknowledge that, when no manifest indication pointed out to me what was to be done, I have consulted the safety of my patient and my own reputation effectually by doing nothing at all."—Thomas Sydenham (1624-1689).

This is what the men from Hennepin County had to say:

"(1) Splenic injury is common following abdominal trauma.

(2) Injury to the spleen must always be sus-

pected if the patient shows signs of shock or abdominal injury, especially if there are fractured ribs on the left or other signs of injury to the left side of the trunk.

(3) Splenic injury may be insidious or delayed in its manifestations and, in lieu of exploration, expectant observation should be carried out for at least seven days in any case of moderate to severe trauma to the left side of the trunk.

(4) As an isolated injury, a traumatically ruptured spleen does not result in a great blood requirement or in great morbidity or mortality. These sequelae are usually the result of other associated injuries sustained at the time of the accident.

(5) Pedestrian injuries carry a higher morbidity, mortality, blood requirement and longer hospital stay than other types of injury.

(6) Anticoagulation is not indicated except for specific complications following splenectomy for traumatic rupture.

(7) The entity of spontaneous rupture of the normal spleen is nonexistent and probably represents overlooked trauma."

And this is part of Doctor Milroy's message:

"In the late winter of 1858 near Redwood Falls, Minnesota Territory a dying Indian mother gave birth to her fifth child, a boy, who later, as a man, would distinguish himself as physician, author, lecturer and leader of his people. However, until the boy could earn a more dignified name he had to bear the name "Hakadah," meaning "the pitiful last."

"About four years later this lad was given a name to be proud of: one that foretold his future success and was determined by a lacrosse contest. To the camp of Mankato or Blue Earth on the Minnesota River, several bands of the eastern Dakotas had come for midsummer contests and festivities. This season the most important event was the lacrosse game between the Kaposia and the Wahpeton bands. With about fifty players on each side, what a contest this must have been! After a long struggle the Wahpetons were victorious when one of their players carried the ball across the opponents' goal line. To the victors went the privilege of giving a new name to one of their worthy little warriors. At a ceremony following the game the little boy, Hakadah, was brought to the center of the circle and received the name Ohiyesa: winner, or one who advances."

Saying It

I have given these excerpts of the winners' prose because the excerpts illustrate that there are different ways of saying things, each effective in the right setting. None of the authors, incidentally, used the traditional IMRAD (Introduction, Methods, Results, and Discussion) approach. And neither do you if you submit an article to this journal. We ask only that you present your message, or argument, or evidence logically and clearly. Whether your combination of words will explode in our minds remains to be seen.

Richard L. Reece, M.D.
Minneapolis, Minnesota

Idiopathic Scoliosis*

THE LOSS OF functional spine stability and adverse cosmetic effects resulting from idiopathic scoliosis are often associated with impairment of pulmonary and cardiac function and emphasize the need for early diagnosis and treatment. Basic and clinical scoliosis research has yielded valuable information concerning genetic influences, structural alterations, and the efficiency of treatment methods to correct the spinal deformity. For those of us not actively involved with scoliosis treatment requiring specialized training and continuous exposure, a basic understanding of its clinical course and early detection is essential to insure prompt and adequate treatment of patients and their families.

Certainly Minnesota is fortunate to have such medical pioneers in the care of crippled children, as Arthur Gillette and Carl Chatterton, when the active treatment of scoliosis was in its infancy. Their early leadership and the development of the Gillette Children's Hospital for Crippled Children created one of the nation's leading centers for the study and treatment of scoliosis. Under the guidance of Doctors John Moe and Robert Winter an active scoliosis service at Gillette Children's Hospital has been developed and maintained to care for affected patients and increase our knowledge about this condition.

With a continued multidisciplinary approach to the problems of scoliosis we shall hopefully advance from a successfully treatable disorder to a preventable one.

Lee C. Detenbeck, M.D.
Rochester, Minnesota

*See page 529.

The Specialized Orthopedic Surgery Program at Gillette Children's Hospital

When Gillette Children's Hospital moved to its present location in Phalen Park in St. Paul, its first concern was as it still is, the proper care of the child handicapped or crippled by an orthopedically improvable condition. The orthopedic staff was concerned with this child's welfare and there was no movement nor attempt to segregate any special orthopedic deformity or disease to any specific staff member.

In 1947 after a meeting of a newly formed small orthopedic group (The Contemporary Orthopedic Club), a Gillette staff member of the Club became interested in the problem of scoliosis. To him it became quite obvious that scoliosis was not as well treated nor managed at Gillette Children's Hospital as it was at the Hospital for Ruptured and Crippled under Dr. John Cobb nor as it was treated at the Milwaukee Children's Hospital under the care of Dr. Walter Blount and Dr. Al Schmidt.

On his return from this meeting he asked the Chief of Staff, Dr. Carl C. Chatterton, if it was possible to establish a scoliosis service at Gillette. The positive answer was quickly forthcoming.

There were some restrictions requested by Dr. Chatterton. The child should not be subjected to extensive surgical procedures which would endanger his survival. Fortunately, this was the era of rapid transition to good surgical care, to better anesthesia, blood replacement, and improved knowledge of surgical physiology, most of which were the aftermath of World War II.

It was an easy step in the surgical treatment of scoliosis to obtain supervision of anesthesia from the anesthesiology department of the University of Minnesota. The newly formed blood bank of the Red Cross Unit of St. Paul provided an ample supply of well matched blood. The danger of operative mortality from extensive surgical procedures on the spine became markedly decreased.

The scoliosis service at Gillette Children's Hospital thus became a reality, under the supervision of Dr. John Moe in January of 1948. Within three months there were 25 scoliosis patients in the hospital, all candidates for surgical correction.

Because of lack of experience, much advice was asked of the current scoliosis authority, Dr. John Cobb of the Hospital for Ruptured and Crippled in New York City. Dr. Cobb was magnanimous in his effort to help.

Since those early days of a subspecialty service in orthopedic surgery at Gillette Children's Hospital, many changes have occurred. The scoliosis service has enlarged and has become one of the nation's centers. Other subspecialty services have been established including club feet, hand problems, amputees, hip disabilities in children, cerebral palsy and myelomeningocele. The last two have become increasingly important for they have been neglected in the past, much as scoliosis had been neglected.

Early diagnosis is the key to quality treatment. The obstetrician must learn to evaluate the newborn infants hips. If there is a question as to hip dyplasia or subluxation, the orthopedic surgeon must be consulted. The pediatrician must be likewise knowledgeable. Myelodysplasia must be recognized at birth and a knowledgeable neurosurgeon and orthopedic surgeon must see the infant within a few hours of his birth.

With this type of progressive approach, pediatric orthopedists have now learned to control or cure conditions considered hopeless 25 years ago.

New Methods of Pain Relief

Intractable pain remains one of the most serious of our unsolved medical problems. Recent advances in the therapy of pain have been in two areas: The first is the development of stereotactic percutaneous cordotomy. This procedure can be done with the patient awake and even seriously debilitated patients can be treated. The procedure is performed under fluoroscopic control and a needle is inserted through the C2 neural foramen laterally into the subarachnoid space. The spinal cord is visualized by the use of emulsified pantopaque and the needle directed into the anterior lateral quadrant of the spinal cord. The spinothalamic tract is then destroyed by electrocoagulation. The overall success rate and complication rate is approximately the same as for open surgical cordotomy, but the procedure is much simpler for the patient and a major operative procedure is avoided by this technique.

The newest investigative area in pain control is in the use of various forms of electrical stimulation for the relief of pain. The electrical stimulation can be used in several ways. External stimulation simply applied on the skin, over motor points, peripheral nerves, or bony prominences will relieve many kinds of pain on a temporary basis. Most patients find the devices too cumbersome for general use, but they are quite effective in temporary pain relief. A second form which has proved very successful, is peripheral nerve stimulation. Permanently implanted electrodes attached to a small radio receiver are placed around the injured nerve from which the pain is emanating. By external controls the patient is able to stimulate transcutaneously and produce sensation in the distribution of the affected nerve which successfully blocks pain. Slight hypesthesia is usually produced, but no disability of motor function. Pain relief after stimulation may be prolonged up to several hours so that the use of the device is intermittent.

Another area where permanent implantation of a stimulating device is employed is in stimulation of the posterior columns. Again a small electrode is placed over the posterior column and attached to a subcutaneously implanted radio receiver. Transcutaneous stimulation from an external power source then produces a tingling sensation in the body below the level of the implantation. This sensation has been successful in blocking pain of a variety of causes: chronic low back syndrome secondary to arachnoiditis, spinal cord injury, phantom limb, cancer and rheumatoid arthritis.

While these procedures are still in the investigative stage, the results obtained so far are highly encouraging. The stimulation procedures seem to be much more effective in normal individuals without significant psychological overlay and the majority of the failures of stimulation have come in patients with serious psychiatric problems. The presence of drug addiction is not a contraindication, but is a problem which must be solved separately after the pain relief is affected.

The next area for exploration in stimulation for pain control is in the use of permanently implanted electrodes within the brain. A great deal of experimental work has been done in animals which indicates that there are several areas in which chronic brain stimulation may be useful for the relief of pain and possibly chronic affective disorders. This work is still very much in the investigative stage, and only a few patients have been so treated. However, preliminary results are highly encouraging and it is expected that this field will develop as the instrumentation is improved.

Sigmoidal Complications of Left Ovarian Enlargement

RAYMOND A. LEE, M.D.;* LOUIS F. SILVERMAN, M.D.† and JOSEPH H. PRATT, M.D.*

DIAGNOSIS, THERAPY, and prognosis of ovarian tumors are predicated on etiologic and histologic factors. Because the ovaries are bilaterally symmetric organs, little thought usually is given to the significance of the side of involvement, other than where to place the abdominal incision.

Enlargement of the right ovary represents no appreciable mechanical hazard to the adjacent ascending colon, and the passage of solid or semiliquid stool rarely is embarrassed. The left ovary, however, is so situated that sigmoid colon and mesentery are in jeopardy should significant ovarian enlargement occur. This is especially true if the patient has had previous pelvic surgery and the bowel is adherent to the left adnexa. Impaired vascular integrity, bowel angulation, or interference with the passage of formed stool may result from the mechanical effects of left ovarian enlargement. Bowel adhesions or mesenteric invasion by the ovarian neoplasm increases the technical problems and associated risk of oophorectomy, and may even result in the necessity for sigmoidal resection.

We have recently had two cases in which an enlarged left ovary impinged on the sigmoid colon, adding appreciably to the technical problems of left oophorectomy and hence prompting this review.

Report of Cases

Case 1

A 28-year-old housewife with known thrombopathy presented with a three to four months' history of melena associated with nausea and an aching left lower quadrant abdominal pain. Ten days before examination she had experienced an acute exacerbation with nausea, emesis, dysuria, and a temperature of 101 F. Her past medical history was relevant in that a total abdominal hysterectomy and right salpingo-oophorectomy were performed five years previously. The postoperative course was complicated by hemorrhage requiring reexploration and ligation of the right uterine and both hypogastric arteries to achieve hemostasis. She subsequently underwent uneventful repair of a vesicovaginal fistula here.

She had a long, cylindrical mass in the left lower quadrant of her abdomen. On pelvic examination the mass was demonstrated to be about 12 cm in diameter, cystic, soft, and semimovable. Routine laboratory examination was unremarkable. Proctologic examination to 15 cm above the dentate line demonstrated the presence of a smooth, soft, probably cystic extrarectal mass. Cystoscopic examination revealed an extrinsic deformity of the left side of the bladder, and excretory urography confirmed the presence of a left lower abdominal soft-tissue mass.

Laparotomy revealed the pelvis mass to be a hemorrhagic cyst of the left ovary, 15 by 10 cm in size. The sigmoid was adherent over the top and lateral to the cyst so that the cyst extended into the mesentery of the sigmoid. With considerable difficulty, sigmoid and mesenteric vessels were mobilized from the dome of the cyst, resulting in two rents of considerable size in the mesentery but not grossly impairing the blood supply to the colon. The cyst was removed intact and proved to be a hemorrhagic endometrioma. The postoperative course was uneventful, except for nausea lasting four days, and the patient was dismissed from the hospital on the eighth postoperative day.

Case 2

A 40-year-old obese housewife, gravida 2, para 2, presented with a six months' history of urinary incontinence and recent onset of rectal pain and blood-tinged rectal discharge. Three years prior to admission she had undergone dilatation and curettage followed by total abdominal hysterectomy and right salpingo-oophorectomy. The pathologic diagnosis was reported as proliferative endometrium and chronic cervicitis. The right tube and ovary were not remarkable.

A lower abdominal mass was palpable, and pelvic examination revealed it to be an eight by 10-cm semimovable left pelvic tumor. Barium enema demonstrated the sigmoid colon to be pushed to the right by an extrinsic soft-tissue mass.

At laparotomy, a 15 by 10-cm multilocular benign serous cystadenoma of the left ovary was found; it was pushing the sigmoid colon far to the right. Careful, tedious mobilization was required to allow intact removal of the cyst. There was no damage to the adherent colon, and its vascular supply seemed adequate. The postoperative course was uneventful.

tomy with additional procedures involving sigmoid colon or sigmoid mesentery were reviewed for the 10-year period, 1956 through 1965. In this group were 40 cases where the integrity of the sigmoid was sufficiently jeopardized for the surgeon to note the need either for careful mobilization or for more extensive procedures involving the sigmoid (Table 1).

TABLE 1
Presenting Symptoms of Complications From Left Ovarian Enlargement

Symptoms	Malig.	Benign	Inflam.	Total

Abdominal pain	4	5	7	16
Fever	1	0	3	4
Hematuria	1	1	0	2

Age at the time of operation ranged from 14 to 85 years, with an average of 47 years. Six patients were 35 years old or younger. Fifteen of the patients had malignant lesions, of which four were bilateral. Seventeen cases involved unilateral benign tumors, while eight were inflammatory masses, of which two were bilateral.

The presenting symptoms were varied and are described in Table 1. The patients frequently had more than one primary complaint. Abdominal pain could be expected to be a major complaint of a group of patients with ovarian tumor, and it was the most commonly elicited symptom. It was generally in the lower abdomen and frequently in the left lower quadrant.

The most interesting finding in this group of patients is the high incidence of bowel symptoms. Eleven of the 40 patients had noted a change in bowel habits, either constipation or thin stools, or even diarrhea, but almost 50% of those with benign lesions had symptoms, presumably because their cystic masses were larger and caused greater mechanical problems. There were 23 additional complaints of bloating, nausea, and melena, all presumably due to the ovarian enlargement encroaching upon the mesentery of the sigmoid or compromising the lumen of the bowel. This is a distinct contrast to the paucity of the gynecologic complaints (10 of 40), six of which were abnormal bleeding. Approximately half the patients knew a mass was present.

Physical findings usually involved the presence of a mass, which was palpable abdominally in 26 cases and by pelvic examination in 40. There were no enormous cysts in this group; the average diameter was 10 to 12 cm and, generally, these pelvic masses were "soft" or "cystic" in nature.

Routine laboratory studies were of little diagnostic aid. Inflammatory conditions were characterized by elevated leukocyte counts and sedimentation rates. Hemoglobin values ranged from 10.1 to 14.5 gm. Leukocyte counts varied from 2,600 to 14,600 (interestingly, the low value was in a patient with an acute tubo-ovarian abscess). Routine urinary examination followed the anticipated pattern, with both malignancy and inflammatory disease producing significant proteinuria and hematuria, but few changes were associated with the benign lesions. The average sedimentation rate in malignancy was 42.4 mm in one hour, ranging from 13 to 110 mm. In those patients with inflammatory disease, sedimentation rate averaged 36.7 mm, varying from 13 to 90 mm, while sedimentation rate in benign ovarian neoplasia averaged 15.6 mm, ranging from 3 to 30 mm.

The results of proctoscopic examination, colon Xray, and urologic examinations are detailed in Table 2. Hysterosalpingography was performed in one patient who had an acute tubo-ovarian abscess and defined obstruction to the left tube.

Technical problems encountered at surgery are described in Table 3. In general, it is necessary to use sharp dissection to mobilize the sigmoid with its mesentery from the underlying left adnexal mass. Identification of the left ureter is also necessary before resection is possible. The sigmoid

and its mesentery may require repair secondary to the surgical trauma. Because of impairment of the blood supply or direct invasion of the sigmoid by the ovarian enlargement, primary sigmoid resection may be necessary. This was necessary in eight instances.

TABLE 3
Technical Problems Encountered at Operation

Problem	No.
Difficulty mobilizing sigmoid	23
Sigmoidal trauma to mesentery	22
Sigmoid resection	8
Bowel repair	9

Discussion

A significant difference in operative risk prevails when comparing oophorectomy with sigmoid resection. As an indication of that difference, hospital mortality figures for these procedures were compared over this same 10-year span. Oophorectomy was associated with a hospital mortality rate of 0.65%, while that for sigmoid resection was 2.76%.

It is apparent that the gynecologic surgeon must be prepared to recognize and treat intestinal disease or that he must have available consultation by a gastrointestinal surgeon.

In the past, many surgeons thought that they could not operate on the unprepared colon without high morbidity and mortality. Herrington and his co-workers[1], and Schnur et al.,[2] have shown that this is not true. Herter and Slanetz[3] reviewed the histories of 1,042 patients who had undergone resection of the colon, some of whom had received antibiotic preparation and some only cleansing enemas. They concluded that, if the anastomosis was made in the peritoneal cavity, postoperative complications occurred at the same ratio in both groups. Therefore, if one finds himself faced with the need to perform a resection of unprepared colon, he should proceed with this treatment unless the intestine is full of hard stool.

In the course of hysterectomy in the premenopausal female, preservation of some ovarian tissue is a common goal. In the absence of ovarian pathology necessitating sacrifice of the right ovary, it appears reasonable to propose that selective removal of the left ovary may forestall the later development of sigmoid complications should ovarian enlargement subsequently occur.

Catatonic Syndrome

The objective changes associated with this syndrome include negativistic reactions, automatic changes, mutism, flexibilitas cerea, and episodes of pathognomonic excitement. Although the catatonic syndrome is seen most frequently in certain psychologic disturbances, such as schizophrenia, it has also been associated with numerous other central nervous system disturbances. Aside from the associated psychogenic relationships, typical catatonic syndromes may occur as a result of trauma to brain tissues. Such psychogenic states have occurred with subdural hematoma, in multiple, discrete, and coalescent areas of the encephalomalacia, and in multiple petechial hemorrhages. Catatonic states have also occurred in acute demyelinization of the central nervous system, in serous meningitis, or in other conditions with which there was an associated increased intracranial pressure.

According to Micheels, several workers have been able to produce a catatonic syndrome in experimental animals, using bulbocapnine, carbon dioxide, nitrogen, and other chemical or biochemical substances. On the basis of these experiments, certain writers have suggested that catatonia is a general reaction occurring as a result of alteration of metabolic functions.

DRIVING ON FREEWAYS is actually safer than on roads and streets close to home. Be extra alert in familiar surroundings.

Bring 'em back ALIVE!

Pre-Sate®
(chlorphentermine HCl)

CAUTION: Federal law prohibits dispensing without prescription.

Indications: Pre-Sate (chlorphentermine hydrochloride) is indicated in exogenous obesity, as a short term (*i.e.*, several weeks) adjunct in a regimen of weight reduction based upon caloric restriction.

Contraindications: Glaucoma, hyperthyroidism, pheochromocytoma, hypersensitivity to sympathomimetic amines, and agitated states. Pre-Sate (chlorphentermine hydrochloride) is also contraindicated in patients with a history of drug abuse or symptomatic cardiovascular disease of the following types: advanced arteriosclerosis, severe coronary artery disease, moderate to severe hypertension, or cardiac conduction abnormalities with danger of arrhythmias. The drug is also contraindicated during or within 14 days following administration of monamine oxidase inhibitors, since hypertensive crises may result.

Warnings: When weight loss is unsatisfactory the recommended dosage should not be increased in an attempt to obtain increased anorexigenic effect; discontinue the drug. Tolerance to the anorectic effect may develop. Drowsiness or stimulation may occur and may impair ability to engage in potentially hazardous activities such as operating machinery, driving a motor vehicle, or performing tasks requiring precision work or critical judgment. Therefore, such patients should be cautioned accordingly. Caution must be exercised if Pre-Sate (chlorphentermine hydrochloride) is used concomitantly with other central nervous system stimulants. There have been reports of pulmonary hypertension in patients who received related drugs.

Drug Dependence: Drugs of this type have a potential for abuse. Patients have been known to increase the intake of drugs of this type to many times the dosages recommended. In long-term controlled studies with high dosages of Pre-Sate, abrupt cessation did not result in symptoms of withdrawal.

Usage In Pregnancy: The safety of Pre-Sate (chlorphentermine hydrochloride) in human pregnancy has not yet been clearly established. The use of anorectic agents by women who are or who may become pregnant, and especially those in the first trimester of pregnancy, requires that the potential benefit be weighed against the possible hazard to mother and child. Use of the drug during lactation is not recommended. Mammalian reproductive and teratogenic studies with high multiples of the human dose have been negative.

Usage In Children: Not recommended for use in children under 12 years of age.

Precautions: In patients with diabetes mellitus there may be alteration of insulin requirements due to dietary restrictions and weight loss. Pre-Sate (chlorphentermine hydrochloride) should be used with caution when obesity complicates the management of patients with mild to moderate cardiovascular disease or diabetes mellitus, and only when dietary restriction alone has been unsuccessful in achieving desired weight reduction. In prescribing this drug for obese patients in whom it is undesirable to introduce CNS stimulation or pressor effect, the physician should be alert to the individual who may be overly sensitive to this drug. Psychologic disturbances have been reported in patients who concomitantly receive an anorexic agent and a restrictive dietary regimen.

Adverse Reactions: Central Nervous System: When CNS side effects occur, they are most often manifested as drowsiness or sedation or overstimulation and restlessness. Insomnia, dizziness, headache, euphoria, dysphoria, and tremor may also occur. Psychotic episodes, although rare, have been noted even at recommended doses. **Cardiovascular:** tachycardia, palpitation, elevation of blood pressure. **Gastrointestinal:** nausea and vomiting, diarrhea, unpleasant taste, constipation. **Endocrine:** changes in libido, impotence. **Autonomic:** dryness of mouth, sweating, mydriasis. **Allergic:** urticaria. **Genitourinary:** diuresis and, rarely, difficulty in initiating micturition. **Others:** Paresthesias, sural spasms.

Dosage and Administration: The recommended adult daily dose of Pre-Sate (chlorphentermine hydrochloride) is one tablet (equivalent to 65 mg chlorphentermine base) taken after the first meal of the day. Use in children under 12 not recommended.

Overdosage: Manifestations: Restlessness, confusion, assaultiveness, hallucinations, panic states, and hyperpyrexia may be manifestations of acute intoxication with anorectic agents. Fatigue and depression usually follow the central stimulation. Cardiovascular effects include arrhythmias, hypertension, or hypotension and circulatory collapse. Gastrointestinal symptoms include nausea, vomiting, diarrhea, and abdominal cramps. Fatal poisoning usually terminates in convulsions and coma.

Management: Management of acute intoxication with sympathomimetic amines is largely symptomatic and supportive and often includes sedation with a barbiturate. If hypertension is marked, the use of a nitrate or rapidly acting alpha-receptor blocking agent should be considered. Experience with hemodialysis or peritoneal dialysis is inadequate to permit recommendations in this regard.

How Supplied: Each Pre-Sate (chlorphentermine hydrochloride) tablet contains the equivalent of 65 mg chlorphentermine base; bottles of 100 and 1000 tablets.

Full information available on request.

Division, Warner-Lambert Company
Morris Plains, New Jersey 07950

for the practical generation

Pre-Sate®
(chlorphentermine HCl)

the trend is toward our kind of anorectic

Not a controlled drug under the Comprehensive Drug Abuse Prevention and Control Act

- low potential for abuse
- less CNS stimulation than with d-amphetamine or phenmetrazine

Effective anorectic adjunct to your program of caloric restriction and diet re-education

- weight loss comparable to d-amphetamine and phenmetrazine, superior to placebo
- convenient one-a-day dosage

P-21-B/W

Pre-Sate® (chlorphentermine HCl)...the increasingly practical appetite suppressant

When you select this familiar antibiotic for IV infusion you have available a broad dosage rang that hospitalized patients may need.

Intravenous Lincocin (lincomycin hydrochloride, Upjohn), with its 1.2 to 8 grams/day dosage range, covers many serious and even life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. Lincocin IV therefore can be as useful in your hospitalized patients as its IM use has proved to be in your office patients. As with all antibiotics, *in vitro* susceptibility studies should be performed.

1.2 to 8 grams/day IV dosage range: Most hospitalized patients with uncomplicated pneumonias respond satisfactorily to 1.2 to 1.8 grams/day of Lincocin IV. These doses may have to be increased for more serious infections. In life-threatening situations as much as 8 grams/day has been administered intravenously to adults.

In usual IV doses, Lincocin (lincomyc hydrochloride, Upjohn) should be diluted in 250 ml or more of normal saline solution or 5% glucose in water But when 4 grams or more per day is given, Lincocin should be diluted in n less than 500 ml of either solution, and the rate of administration should not exceed 100 ml/hour. Too rapid intravenous administration of doses exceeding 4 grams may result in hypotension or, in rare instances, cardiopulmonary arrest.

Effective gram-positive antibiotic: Lincocin IV is effective in respiratory tract, skin and soft-tissue, and bone

ifections caused by susceptible strains
pneumococci, streptococci, and
aphylococci, including penicillin-
sistant strains. Staphylococcal strains
sistant to Lincocin (lincomycin
ydrochloride, Upjohn) have been
covered. Before initiating therapy,
lture and susceptibility studies should
performed. Lincocin has proved
luable in treating patients hyper-
nsitive to penicillin or cephalosporins,
nce Lincocin does not share
tigenicity with these compounds.
owever, hypersensitivity reactions
ve been reported, some of these in
tients known to be sensitive to
nicillin.

ell tolerated at infusion site: Lincocin
travenous infusions have not
oduced local irritation or phlebitis,
ien given as recommended. Lincocin
usually well tolerated in patients who
e hypersensitive to other drugs.
evertheless, Lincocin should be used
utiously in patients with asthma or
gnificant allergies.

patients with impaired renal function,
e recommended dose of Lincocin
ould be reduced to 25—30% of
e dose for patients with normal
dney function. Its safety in
egnant patients and in infants
ss than one month of age has
t been established.

ncocin may be used with other
timicrobial agents: Since Lincocin
stable over a wide pH range, it is
itable for incorporation in
travenous infusions; it also may be
administered concomitantly with other antimicrobial agents when indicated. However, Lincocin should not be used with erythromycin, as *in vitro* antagonism has been reported.

Lincocin®

Sterile Solution (300 mg per ml)

(lincomycin hydrochloride, Upjohn)

For further prescribing information, please see following page.

© 1972 The Upjohn Company

Sterile Solution (300 mg. per ml.)

Lincocin®

(lincomycin hydrochloride, Upjohn)

Up to 8 grams per day by IV infusion for hospitalized patients with life-threatening infections. Lincocin is effective in infections due to susceptible strains of streptococci, pneumococci, and staphylococci. As with all antibiotics, *in vitro* susceptibility studies should be performed.

Each preparation contains:	Lincomycin hydrochloride monohydrate equivalent to lincomycin base
250 mg Pediatric Capsule	250 mg
500 mg Capsule	500 mg
*Sterile Solution per 1 ml	300 mg
Syrup per 5 ml	250 mg

*Contains also: Benzyl Alcohol 9 mg; and, Water for Injection—q.s.

Lincocin (lincomycin hydrochloride) is indicated in infections due to susceptible strains of staphylococci, pneumococci, and streptococci. *In vitro* susceptibility studies should be performed. Cross resistance has not been demonstrated with penicillin, ampicillin, cephalosporins, chloramphenicol or the tetracyclines. Some cross resistance with erythromycin has been reported. Studies indicate that Lincocin does not share antigenicity with penicillin compounds.

CONTRAINDICATIONS: History of prior hypersensitivity to lincomycin or clindamycin. Not indicated in the treatment of viral or minor bacterial infections.

WARNINGS: *CASES OF SEVERE AND PERSISTENT DIARRHEA HAVE BEEN REPORTED AND HAVE AT TIMES NECESSITATED DISCONTINUANCE OF THE DRUG. THIS DIARRHEA HAS BEEN OCCASIONALLY ASSOCIATED WITH BLOOD AND MUCUS IN THE STOOLS AND HAS AT TIMES RESULTED IN AN ACUTE COLITIS. THIS SIDE EFFECT USUALLY HAS BEEN ASSOCIATED WITH THE ORAL DOSAGE FORM BUT OCCASIONALLY HAS BEEN REPORTED FOLLOWING PARENTERAL THERAPY.* A careful inquiry should be made concerning previous sensitivities to drugs or other allergens. Safety for use in pregnancy has not been established and Lincocin (lincomycin hydrochloride) is not indicated in the newborn. Reduce dose 25 to 30% in patients with severe impairment of renal function.

PRECAUTIONS: Like any drug, Lincocin should be used with caution in patients having a history of asthma or significant allergies. Overgrowth of nonsusceptible organisms, particularly yeasts, may occur and require appropriate measures. Patients with pre-existing monilial infections requiring Lincocin therapy should be given concomitant antimonilial treatment. During prolonged Lincocin therapy, periodic liver function studies and blood counts should be performed. Not recommended (inadequate data) in patients with pre-existing liver disease unless special clinical circumstances indicate. Continue treatment of β-hemolytic streptococci infections for 10 days to diminish likelihood of rheumatic fever or glomerulonephritis.

ADVERSE REACTIONS: *Gastrointestinal*—Glossitis, stomatitis, nausea, vomiting. Persistent diarrhea, enterocolitis, and pruritus ani. *Hemopoietic*—Neutropenia, leukopenia, agranulocytosis, and thrombocytopenic purpura have been reported. *Hypersensitivity reactions*—Hypersensitivity reactions such as angioneurotic edema, serum sickness, and anaphylaxis have been reported, sometimes in patients sensitive to penicillin. If allergic reaction occurs, discontinue drug. Have epinephrine, corticosteroids, and antihistamines available for emergency treatr it. *Skin and mucous membranes*—Skin ra s, urticaria, vaginitis, and rare instances o v exfoliative and vesiculobullous dermatitis ve been reported. *Liver*—Although no dire e lationship to liver dysfunction is establi d, jaundice and abnormal liver function as (particularly serum transaminase) have en observed in a few instances. *Cardiovas ar*—Instances of hypotension following p n teral administration have been repo d, particularly after too rapid IV admin a tion. Rare instances of cardiopulmonar ar rest have been reported after too rapi V administration. If 4.0 grams or more ad n istered IV, dilute in 500 ml of fluid ad administer no faster than 100 ml per l ur *Special senses*—Tinnitus and vertigo ve been reported occasionally. *Local reac ns*—Excellent local tolerance demonstrat to intramuscularly administered Linc in (lincomycin hydrochloride). Reports of in following injection have been infreq ly Intravenous administration of Lincoc in 250 to 500 ml of 5% glucose in dis ed water or normal saline has produce no local irritation or phlebitis.

HOW SUPPLIED: *250 mg* and *500* Capsules—bottles of 24 and 100. *S le Solution, 300 mg per ml*—2 and 10 ml als and 2 ml syringe. *Syrup, 250 mg per* —60 ml and pint bottles.

Dr. Carl C. Chatterton and Gillette Children's Hospital

J. H. MOE, M.D. and R. B. WINTER, M.D.

THE ORTHOPEDIC SURGEON of today enters his practice after four or more years of concentrated study, instruction and practice of his specialty. He must demonstrate his capabilities in this specialty by passing a rigid examination before he is certified as a specialist.

In the early years of this century, the training of the orthopedic surgeon was quite different. Once he decided on an orthopedic career, he sought areas and institutions where he could be exposed to men whose primary interest lay in this field. He endeavored to obtain an association with such men and to act as their assistant. Often, he hoped to become a partner to such a man.

Such were the aims and ambitions of Dr. Carl Chatterton when he first came to St. Paul, Minnesota in 1910 to assist in the care of indigent crippled children at the Minnesota State Hospital and during the following year when he was an intern at the City and County Hospital. He had a good friend in Dr. Ancker during that year of internship and he took Dr. Ancker's sage advice that, "If you watch your P's and Q's you might land a job with Dr. Gillette."

Dr. Arthur Gillette

Dr. Arthur Gillette was a pioneer orthopedic surgeon. He attended Hamline University in St. Paul and later the Minnesota Hospital College from 1883 until 1885. He transferred his allegiance to the reorganized St. Paul Medical College in 1886, the year he was graduated. He specialized in the orthopedic care of the crippled and deformed child and his intense interest was in the field of children's orthopedics. He initiated the thought of a state controlled and financed institution for the care of the indigent crippled child in 1897 when he appeared before the legislative body known as the Minnesota Conference of Charities and Corrections. He read to them a paper entitled "The Duty of the State to its Crippled and Deformed Children."

Dr. Gillette was helped in his endeavors by a crippled girl named Jessie Haskins who the year before had presented a plea to that same legislative body for state help to the indigent crippled

Fig. 1—Gillette Children's Hospital in the horse and buggy days, approximately 1910.

child. The paper in 1897 read by Gillette was followed the same year by another plea by Jessie Haskins begging them for help.

The joint efforts of this crippled girl and Gillette met with success, particularly when he offered his services free to give orthopedic help to the crippled child. A bill was passed by the legislature of Minnesota providing such a state aid—the first state in the Union to do so.

The state law to provide for the care, education, and treatment of the indigent, crippled and deformed children of the State of Minnesota was passed in 1897. The Board of Regents of the University of Minnesota was given the power to act in its formation and supervision and $5,000 was appropriated for its support.

The City and County Hospital in St. Paul was its first home. A ward was given exclusively for the care of these children at a rate so low that is was possible to care for 80 children during the first two years of the institution's existence. Appropriations then came more easily and the work increased so rapidly that the ward became filled. The necessity of a separate building became apparent. A structure adjoining the City and County Hospital was then used. This structure was donated to the State of Minnesota by the City of St. Paul in 1907. A group of St. Paul citizens, the Commercial Club and the Business League, responded the same year with a purchase of twenty-three acres of land near the outskirts of St. Paul. This was also given to the State. This land was adjacent to what later became Phalen Park and is the present site of Gillette Children's Hospital.

In 1907 the State Board of Control was put in charge of the Minnesota State Hospital for Indigent Crippled and Deformed Children. In 1909, $55,000 was appropriated to construct the first portion of the present building on the land adjoining Phalen Park. In 1913, $60,000 more was appropriated to build an addition. The same year the property adjoining the City and County Hospital was given back to the City of St. Paul and all the children were transferred to the new building near Phalen Park.

Dr. Carl Chatterton

Dr. Carl Chatterton was born in the small country town of Peterson, Iowa in 1885. His father, Allen Smith Chatterton, (Mother—Jennie) was a general practitioner, a country doctor of the type now almost extinct.

He took his medical education at Northwestern University and during his senior year he saw a message on the blackboard indicating that the City and County Hospital in St. Paul offered an examination for interns. Dr. Chatterton and three of his classmates took this examination and shortly thereafter, Dr. Ancker came to Chicago to tell them of the fine internship at his hospital. Two years were offered, one in orthopedics at the Minnesota State Hospital, the other at the City and County Hospital. Dr. Chatterton was interested in the thought of helping the crippled children and he accepted these offers although prior to this he had planned on obstetrics.

During these years he gained the confidence and friendship of Dr. Gillette. At the completion of his internship he was offered an association with this well known orthopedic surgeon. This he proudly accepted.

He retained this association until the death of Dr. Gillette on March 24, 1921. He developed a sound and lasting knowledge of general orthopedics but his love for children's orthopedics predominated.

With the death of Dr. Gillette came the ap-

Fig. 2—Dr. Chatterton and a patient with tuberculosis of the spine, approximately 1930.

pointment of Dr. Chatterton to the position of Chief of Staff of the Minnesota State Hospital for Indigent Crippled and Deformed Children.

It was renamed in 1925 by an act of the legislature to honor Dr. Gillette in recognition of his work on behalf of the crippled child. Since then, it has been known as Gillette Children's Hospital. Dr. Chatterton served as its Chief of Staff from 1921 to 1955.

More appropriations for further additions were authorized. In 1925, the Michael Dowling Memorial Hall was donated by Dowling and the Bankers Association of St. Paul. This added an auditorium with an adjoining library, school, and classroom facilities.

Chatterton continued as Chief of Staff until 1955 when at the age of 70 he made the decision to resign as Chief. He has continued to be on the active Orthopedic Service Staff and his interest and attention to the orthopedically handicapped child remains undimmed. Since his semi-retirement the growth and expansion of Gillette Children's Hospital continued.

For many years following World War I the administration of the hospital was in the capable hands of Miss Elizabeth McGregor while the school of Nursing was supervised by her sister, Miss Margaret McGregor. It was during these years that many of the happy memories of Gillette Children's Hospital developed. Dr. Chatterton still vividly recalls the performing parrot, Polly, who could imitate the children and whose talking abilities caused much laughter and often some concern.

Dr. Chatterton recalls also the days of the influenza epidemic in 1919 when many children died in the hospital; some days as many as four or five. Children who had skeletal and joint tuberculosis were easy victims of this devastating epidemic.

While under the direction of Miss McGregor. the out-patient department was relocated and recreation room facilities were added. In 1949, when Miss Elizabeth McGregor retired, Miss Jean Conklin became administrator of Gillette Children's Hospital. Under her direction the hospital program has continued to grow. In 1959, a new Service Wing was constructed which included an x-ray laboratory, dentistry, speech, and hearing facilities, photography laboratory, central supply, and a new braceshop. In 1960 a surgical wing was

Fig. 3—Dr. Chatterton making rounds, April, 1970.

Fig. 4—Dr. Chatterton standing beside the painting of Dr. A. J. Gillette, founder of the Hospital.

built which included two new operating rooms, remodeling of one old operations room, a new cast room, a new postoperative recovery room, a doctor's lounge and locker room, and offices.

Gillette Children's Hospital

In 1959, the legislature passed a law enabling Gillette Children's Hospital to collect on hospital insurance carried by the parents of the patients if such insurance was available. In 1967, the legislature passed a law enabling Gillette Children's Hospital to bill parents according to their ability to pay and to collect from all other available sources including insurance companies and federally-financed health programs. In 1967, the legislature also passed a law creating the Medical Education and Research Account Fund allowing surgical fees to be collected by the doctors for this fund to be used in medical education and research.

Many orthopedic surgeons have received their training in children's orthopedics at Gillette Children's Hospital under Dr. Chatterton since residents first came under his supervision there in 1921. Many also have spent a period of their internship there and some of them thereby developed an interest which led them to continue training in orthopedic surgery. The present orthopedic staff is largely made up of men who have spent a year of their training in children's orthopedics at this institution.

Throughout the many years that Dr. Chatterton was Chief of Staff at Gillette Children's Hospital, he was first and foremost a superb teacher. He is Emeritus Associate Professor in Orthopedic Surgery at the University of Minnesota. He is a senior member of the American Orthopedic Association. He was a founding member of the Central States Orthopedic Society, later renamed the Clinical Orthopedic Society. He also founded the Minnesota-Dakota Orthopedic Society.

After sixty years of continuous service to the Crippled Children of the State of Minnesota, Dr. Chatterton is now retiring from active participation in the care of Gillette Children's Hospital patients.

His interest in their future remains unaltered. We hope that Minnesota will always be a place where such pioneers can see their dreams fulfilled.

The Development of an Alcoholism Unit in a Private General Hospital

THE REVEREND PHILIP L. HANSEN*

IF A PERSON IS sick enough to die from the uncontrolled use of alcohol or to destroy his life and those he loves, it would seem that he ought to be considered sick enough to be admitted to a community hospital and to receive the kind of care he deserves.

In 1944, a special committee of the American Hospital Association recommended that "The primary point of attack (on alcoholism) should be through the general hospital. Because of the completeness of its facilities and of its accessibility, it is the logical place to which an alcoholic or his family would turn." This statement was approved by the American Hospital Association in 1957. It has only been recently that this concept has been put into practice. St. Mary's alcoholism unit in Minneapolis opened in December 1968, and the unit at Northwestern began to receive patients on July 27, 1970. Both of these units were filled in a week and have remained full. I am working closely with St. John's Hospital in St. Paul and St. Cloud Hospital in St. Cloud both of which soon will start programs similar to ours.

The unit at Northwestern Hospital would not exist were it not for the fact that a few staff physicians and others realized that alcoholism is treatable. In a number of instances they had had experience, within their family, of successful treatment elsewhere, so they became the driving force in supporting Northwestern's treatment unit.

Current Staffing

The most difficult aspect of beginning such a unit is the staffing. At present I have the following personnel, most of them arrested alcoholics: a head nurse, a psychologist, three counselors on alcoholism, a person as liaison between Alcoholics Anonymous and outpatient resources, and a graduate theologian working in the outpatient follow-up program. Besides this first line staff there are the other nurses, L.P.N.'s, clergy, orderlies, and so on. I hire the people who will work in our unit because I want people who have some empathy for the alcoholic and his illness. To be effective in this work you must unlearn your discipline and be willing to learn some new skills. A good therapist may be found among the trades or even among the clergy. Northwestern Hospital had never hired a clergyman, and when the word came that a preacher was going to head up the alcoholism treatment unit there was some vigorous criticism. Nevertheless, this is not the kind of work for which you can hire people on the basis of a standard job application. You must have some measure of their ability to communicate with people, and they must have some insight into the dynamics of this illness, alcoholism.

Program

The first objective in treating the alcoholic is to receive the patient and keep

*Director, Alcoholism Unit, Northwestern Hospital, Minneapolis.

him alive. At this point everyone works to support the physicians and nurses. Detoxification is the first step, and perhaps the easiest part of the entire treatment routine. The basic goal is to withdraw the patient from all mood-modifying chemicals as safely and quickly as possible. This is the task of the medical staff and they do it effectively. Almost all of the detoxification is done in the same hospital room the patient will occupy in the weeks to come. In 120 admissions up to the end of October at Northwestern Hospital only three patients were moved to intensive care or to another medical unit because of complications. Nevertheless, the risk of complications is one of the things that has convinced me that alcoholism should be treated in the community hospital. The availability of the broad range of medical services is very reassuring to everyone on the unit's staff. When the patient arrives, the vital statistics have been gathered, and the doctor has been consulted, the nurses move into one of the routines that has been established, and the early part of treatment is begun.

When the patient has been detoxified he enters the flow of the treatment program. At 9 a.m. each weekday one of the 12 steps of Alcoholics Anonymous (AA) is lectured on and discussed. Then general group therapy sessions begin. After lunch there is a lecture or audiovisual presentation. The latter part of the afternoon is spent reading, going for a walk in the park, or visiting with the counselor. Each evening there is either a lecture by some consultant or an activity of AA that involves the outside community. Some of the finest communicators in the field of alcoholism come in and talk to the patients. Early in the patient's hospital stay, we inform AA (in the area where the person lives) and tell them that the patient is in the treatment unit. An AA representative is asked to contact the patient and his spouse, who will be introduced to AA in their home area while treatment continues at Northwestern.

Two afternoons a week the spouse is asked to come to the hospital for the couple's group therapy. This procedure has proven to be very helpful. On Sunday the patients who choose to do so are taken to church near the hospital.

No patient is admitted to the unit unless they agree to stay for a minimum of 21 consecutive days. This does not mean it is a 21-day treatment, but rather a minimum open-end stay. The average stay is about one month, with the women remaining a bit longer than the men.

If the patient's hospitalization program does not cover treatment for alcoholism, the Hospital requires a cash deposit to cover a minimum stay of 21 days. This causes us some frustration when the patient wants in, but also prevents many financial problems after the patient has left. We have had excellent support from the hospitalization insurance companies, which only further supports the premise that this illness should be treated in the hospital. Every patient in our unit is admitted with a diagnosis of alcoholism, which is exciting in itself when we recollect how long the physician has had to go through diagnostic and moral gymnastics to get the patient into the hospital for detoxification. Each bed in the alcoholism unit is an acute bed and the cost is the same per day as any other acute bed in the hospital.

The Unit's task is to take a chemically dependent person, get him well physically, and then prepare him to go back to society to live and to cope as comfortably as possible with reality. We try to use every available resource and skill to do this. The greatest healing is done by the patients themselves. What we on the staff attempt to do is create a healing milieu.

Physical Setting

We inherited a brand new circular unit not unlike any circular unit of us

has seen. We took the nurses' station out of the middle and put it near the entrance. In the center is a lounge area. When the alcoholic patient goes to treatment, part of his problem is dehumanization and desocialization. The patients in the unit are together whether they like it or not, and this aspect of treatment I would hate to give up. It is too easy for the patient who has been running away, to run away to his room at the end of some long hall. We have no private rooms, either, because they, too, permit desocialization to continue.

Cooperation with the Medical Staff

Cooperation from the medical staff has been excellent. Fifteen doctors from several specialities have volunteered to take patients who have no staff physician. Staff physicians are encouraged to follow their patients through the treatment program. At times the system may be cumbersome, but in the long run there will be many doctors well versed in detoxification and the dynamics of such treatment. Teamwork with lay counselors is essential. This is a good example of using paramedical personnel to the utmost.

When one out of 20 employees in America—including executives—has alcoholism, it's time for some plain talk about alcoholism. The alcoholic's family, friends and employer may mean well, but the silent treatment is no way to treat a disease. And alcoholism is a disease from which recovery is possible, rather than a moral weakness for which the alcoholic should be pitied—or fired. It's a disease which ranks with heart disease, cancer and severe mental disorders as a public health menace.

The National Council on Alcoholism has pioneered in setting up joint union-management alcoholism programs. In these programs, industry is achieving *recovery rates averaging 60 to 70 percent*. Management profits by retaining its experienced employees and regaining lost productivity—estimated at six billion dollars. Unions profit by increasing health and welfare protection for members and keeping them in the active work force.

If you think alcoholism is affecting your business, **talk it over with the Director of Labor Management Services, National Council on Alcoholism, 2 Park Avenue, New York, N.Y. 10016.**

STUART PHARMACEUTICALS | Division of ICI America Inc. | Wilmington, Del. 19899 | Pasadena, Calif. 91109

a new outlook in chronic pain

of moderate to severe intensity

Though Talwin® can be compared to codeine in analgesic efficacy, it is not a narcotic. So patients receiving Talwin for prolonged periods face fewer of the consequences you've come to expect with narcotic analgesics. And that, in the long run, can mean a better outlook for your chronic-pain patient.

Talwin Tablets are:

- **Comparable to codeine in analgesic efficacy:** one 50 mg. Talwin Tablet appears equivalent in analgesic effect to 60 mg. (1 gr.) of codeine. Onset of significant analgesia usually occurs within 15 to 30 minutes. Analgesia is usually maintained for 3 hours or longer.
- **Tolerance not a problem:** tolerance to the analgesic effect of Talwin Tablets has not been reported, and no significant changes in clinical laboratory parameters attributable to the drug have been reported.
- **Dependence rarely a problem:** during three years of wide clinical use, only a few cases of dependence have been reported. In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.
- **Not subject to narcotic controls:** convenient to prescribe—day or night—even by phone.
- **Generally well tolerated by most patients:** infrequently cause decrease in blood pressure or tachycardia; rarely cause respiratory depression or urinary retention; seldom cause diarrhea or constipation. If dizziness, lightheadedness, nausea or vomiting are encountered, these effects tend to be self-limiting and to decrease after the first few doses. (See last page of this advertisement for a complete discussion of adverse reactions and a brief discussion of other Prescribing Information.)

50 mg. Tablets

Talwin®

brand of

pentazocine (as hydrochloride)

the long-range analgesic

a new outlook in chronic pain

of moderate to severe intensity

Contraindications: Talwin, brand of pentazocine (as hydrochloride), should not be administered to patients who are hypersensitive to it.

Warnings: *Head Injury and Increased Intracranial Pressure.* The respiratory depressant effects of Talwin and its potential for elevating cerebrospinal fluid pressure may be markedly exaggerated in the presence of head injury, other intracranial lesions, or a preexisting increase in intracranial pressure. Furthermore, Talwin can produce effects which may obscure the clinical course of patients with head injuries. In such patients, Talwin must be used with extreme caution and only if its use is deemed essential.

Usage in Pregnancy. Safe use of Talwin during pregnancy (other than labor) has not been established. Animal reproduction studies have not demonstrated teratogenic or embryotoxic effects. However, Talwin should be administered to pregnant patients (other than labor) only when, in the judgment of the physician, the potential benefits outweigh the possible hazards. Patients receiving Talwin during labor have experienced no adverse effects other than those that occur with commonly used analgesics. Talwin should be used with caution in women delivering premature infants.

Drug Dependence. There have been instances of psychological and physical dependence on parenteral Talwin in patients with a history of drug abuse and, rarely, in patients without such a history. Abrupt discontinuance following the extended use of parenteral Talwin has resulted in withdrawal symptoms. There have been a few reports of dependence and of withdrawal symptoms with orally administered Talwin. Patients with a history of drug dependence should be under close supervision while receiving Talwin orally.

In prescribing Talwin for chronic use, the physician should take precautions to avoid increases in dose by the patient and to prevent the use of the drug in anticipation of pain rather than for the relief of pain.

Acute CNS Manifestations. Patients receiving therapeutic doses of Talwin have experienced, in rare instances, hallucinations (usually visual), disorientation, and confusion which have cleared spontaneously within a period of hours. The mechanism of this reaction is not known. Such patients should be very closely observed and vital signs checked. If the drug is reinstituted it should be done with caution since the acute CNS manifestations may recur.

Usage in Children. Because clinical experience in children under 12 years of age is limited, administration of Talwin in this age group is not recommended.

Ambulatory Patients. Since sedation, dizziness, and occasional euphoria have been noted, ambulatory patients should be warned not to operate machinery, drive cars, or unnecessarily expose themselves to hazards.

Precautions: *Certain Respiratory Conditions.* Although respiratory depression has rarely been reported after oral administration of Talwin, the drug should be administered with caution to patients with respiratory depression from any cause, severe bronchial asthma and other obstructive respiratory conditions, or cyanosis.

Impaired Renal or Hepatic Function. Decreased metabolism of the drug by the liver in extensive liver disease may predispose to accentuation of side effects. Although laboratory tests have not indicated that Talwin causes or increases renal or hepatic impairment, the drug should be administered with caution to patients with such impairment.

Myocardial Infarction. As with all drugs, Talwin should be used with caution in patients with myocardial infarction who have nausea or vomiting.

Biliary Surgery. Until further experience is gained with the effects of Talwin on the sphincter of Oddi, the drug should be used caution in patients about to undergo surgery of the biliary t

Patients Receiving Narcotics. Talwin is a mild narcotic antago Some patients previously receiving narcotics have experienced withdrawal symptoms after receiving Talwin.

CNS Effect. Caution should be used when Talwin is administ to patients prone to seizures; seizures have occurred in a few patients in association with the use of Talwin although no cause effect relationship has been established.

Adverse Reactions: Reactions reported after oral administr of Talwin include *gastrointestinal:* nausea, vomiting; infrequ constipation; and rarely abdominal distress, anorexia, diar *CNS effects:* dizziness, lightheadedness, sedation, euphoria, h ache; infrequently weakness, disturbed dreams, insomnia, syn visual blurring and focusing difficulty, hallucinations (see *A CNS Manifestations* under WARNINGS); and rarely tremor, tability, excitement, tinnitus. *Autonomic:* sweating; infrequ flushing; and rarely chills. *Allergic:* infrequently rash; and ra urticaria, edema of the face. *Cardiovascular:* infrequently dec in blood pressure, tachycardia. *Other:* rarely respiratory depres urinary retention.

Dosage and Administration: *Adults.* The usual initial adult do 1 tablet (50 mg.) every three or four hours. This may be incre to 2 tablets (100 mg.) when needed. Total daily dosage should exceed 600 mg.

When antiinflammatory or antipyretic effects are desired in a tion to analgesia, aspirin can be administered concomitantly Talwin.

Children Under 12 Years of Age. Since clinical experience in l dren under 12 years of age is limited, administration of Talwi this age group is not recommended.

Duration of Therapy. Patients with chronic pain who have rec Talwin orally for prolonged periods have not experienced w drawal symptoms even when administration was abruptly dis tinued (see WARNINGS). No tolerance to the analgesic effect been observed. Laboratory tests of blood and urine and of liver kidney function have revealed no significant abnormalities a prolonged administration of Talwin.

Overdosage: *Manifestations.* Clinical experience with Talwin o dosage has been insufficient to define the signs of this condition.

Treatment. Oxygen, intravenous fluids, vasopressors, and c supportive measures should be employed as indicated. Assiste controlled ventilation should also be considered. Although n phine and levallorphan are *not* effective antidotes for respira depression due to overdosage or unusual sensitivity to Talwin, r enteral naloxone (Narcan®, available through Endo Laboratorie a specific and effective antagonist. If naloxone is not available, r enteral administration of the analeptic, methylphenidate (Rital may be of value if respiratory depression occurs.

Talwin is not subject to narcotic controls.

How Supplied: Tablets, peach color, scored. Each tablet con Talwin (brand of pentazocine) as hydrochloride equivalent to 50 g base. Bottles of 100.

Winthrop Winthrop Laboratories, New York, N. Y. 10016 (15

Special Article

Systematized Nomenclature of Pathology

Conversion to the Computer Language of Medicine

ARTHUR H. WELLS, M.D.*

A DESCRIPTION OF the unique characteristics of the Systematized Nomenclature of Pathology[1] (SNOP) follows. A few highlights of the gestational period of SNOP with results of the Field Trial Edition and its Visual Aid are covered. The story would not be complete without reviewing the frustrating experiences with the World Health Organization (WHO) and the Council on International Organizations of Medical Sciences (CIOMS).

You will forgive a recording of some of the successes which have spurred the committee on to establish a master system to contain the whole of clinical medicine. For one thing all hospital records should be in one code and for another medical science should not be handicapped by failing to develop a computer language of all of medicine, an accomplishment long overdue.

Unique Identity

The SNOP published in 1965 by the College of American Pathologists is indeed a unique classification, coding system and nomenclature of medical diagnostic terms. One could create a usable coding system of medical terms by attaching numeric equivalents to a haphazard collection of names of diseases and agents. For this one need simply to arrange these terms with their codes in alphabetic order. The Current Medical Information and Terminology[2] (CMIT) of the American Medical Association (AMA) could be an example. The CMIT serves a much needed purpose as an official dictionary with French, German and Spanish cross reference but not a storage and retrieval vehicle, let alone a computer language of medicine. Classification and definition are the essence of knowledge. Classification alone delimits entities, defines knowledge, exposes ignorance, advances understanding, permits comparison, reveals interrelationships, promotes varied generalizations and indicates areas of needed investigation and research. CMIT plus a Systematized Nomenclature of Medicine (SNOMed) based on SNOP would be a profound contribution to medical science. Current Procedural Terminology[3] (CPT) of the AMA may well be accepted as the fifth therapeutic and procedural field of SNOP.

SNOP as a Classification System

The SNOP was developed as a detailed classification of all of its entities as they relate to each other. The unique separation of the medical diagnostic terms into their basic linguistic components of site, visible alteration, physiologic activity and etiologic entity was the result of independent advice of two distinguished biometrions, E. Cuyler Hammond of the American Cancer Society, Inc. and Harold Dorn of the National Institutes of Health (deceased).

These four fields named Topography (T), Morphology (M), Function (F), and Etiology (E), became the basis for a skeleton of a decimal and duodecimal classification. With four digits, 9,999 groupings and entities can be placed in each field, beyond this alphabet letters can be used for the last two digits. The first edition has 22,428 entries in the combined alphabetic indices. Room was left in all fields, sections and groups for expansion.

Topography

For practical reasons including frequency of disease in certain sites and number of anatomic structures, Topography was arranged into 140 two-digit sites and areas. Each of these was expanded into a four-digit code which together contain over 4,000 detailed anatomic entities in the first edition. The practical need of a two-digit code for 140 sites necessitated the use of a duodecimal division. In the mid-sixties the most efficient computer handling of this was by the use of the single punches + and −. We called them X and Y. They required only one pass

*4640 London Road, Duluth, Minnesota, 55804.

through the card sorter whereas alphabetic codes per se required two passes.

Our topology terms were taken from the internationally accepted "Nomia Anatomica." The decimal systems of M, F and E permit any degree of utilization depending on the interests of the user. Thus pure morphologists could use only Topography and Morphology or a psychiatric diagnosis could be reduced to one general term in the psychiatric field of Function or one of ten subgroup titles.

"Unit of Information"

An analysis of the defects of the Standard Nomenclature of Diseases and Operations[4] (SNDO) led to an attempt at creating a "unit of information" system of medical coding so basic in a linguistic code. An etiologic agent or a physiologic alteration of a given lesion must be coded separately; thus - acute staphylococcic pneumonia with acidosis is acute pneumonia (T and M) staphylococcus (E), acidosis (F).

Furthermore, only one morphologic complication was coded to a disease process; thus - ruptured duodenal ulcer with hemorrhage and peritonitis is duodenal ulcer with rupture (T and M) duodenal ulcer with hemorrhage (T and M) peritonitis (T and M).

Creating a Nomenclature

In addition to a classification and a coding system, an attempt was made to create a nomenclature. Granted, an international agreement on medical terms and their meanings is eventually imperative. Witness the twenty year practically unsuccessful struggle of the International Union Against Cancer to arrive at preferred names of the neoplasms. A common language acceptable to nearly all races and nations is a certainty given sufficient time.

In SNOP a preferred term receives first listing while synonyms are placed below and inset thus:

8483 Mucinous adenocarcinoma
Mucinous carcinoma
Colloid carcinoma
Colloid adenocarcinoma
Gelatinous carcinoma
Gelatinous adenocarcinoma

This is considered the scientific and logical method of arriving at general agreement on obsolescence. That is when the term has fallen into disuse, it is eliminated and does not hang around forever. In reverse, a new term can be added as a synonym if it becomes generally accepted.

Structuring the Computer

This type of nomenclature has a fundamental practical value for structuring the computer. Once it has been "taught" the preferred terms and their synonyms it can store them under one code number and on retrieval it will print out the preferred term. Since 25 percent of the 22,428 entries in the alphabetic indices of SNOP are synonyms one can easily see why an unstructured computer system such as that of Chandler-Smith could hardly be expected to properly retrieve its input especially with the conflicting individuality of several physicians. On the other hand unstructured natural language systems will accept practically anything you wish to store. There will be more on this subject later.

History of the Construction of SNOP

For those mathematically inclined, this thesis has necessitated a recent review of 72 inches of those communications which were saved and not relegated to the wastebasket. Stacked one sheet upon the next these sheets run 200 to the inch for a grand total of 14,400. Each letter has an average of 30 typewritten lines, but then I didn't read every line or page.

The original Committee on Nomenclature and Classification of Diseases, in spite of its distinguished membership, had not accomplished much in five years. Frank Queen, the Chairman, explained that there were no funds available. In late 1957 a series of letters concerning action resulted in the resignation of all but one member. A newly appointed group communicated their original ideas by mail. All felt that additions to or a separate section of SNDO was indicated. A large number of classifications were collected from institutions throughout the country.

First Meeting of Committee

The first meeting of the committee was held in June of 1958 at the new AFIP building in Washington. Here the futility of using SNDO was agreed to by all. A good beginning on a classification of morphologic alterations was accomplished. Once a skeleton classification was agreed upon a division of the work of collecting the entities was easy.

Subcommittees and Grants

Subcommittees established groups and individual entries with code numbers within the larger fields and sections. By 1959 the American Cancer Society, Inc. (ACS) agreed to provide the assistance of its statistical and computer departments to the effort with the invaluable assistance of E. Cuyler Hammond and his assistant, Mrs. Constance Percy. In September of 1960 we received a research grant from the National Institutes of Health of approximately $50,000 a year for three years. After this there were committee meetings every two months with intervening subcommittee meetings. Frequently disagreements led to heated arguments. There are twenty rejected classifications of the field of Topography in the files.

Enlarged Committee

By 1961 the committee was enlarged by five pathologists with special interest in the various disciplines of clinical pathology. They completed the field of Function. Of all the contributors in and out of the committee, the work of Sheldon C. Sommers and Louis B. Thomas was exceptional, especially the weeks spent compiling the returns from the field trial and editing the first edition.

Field Trial Edition and Its Visual Aid

Three hundred and fifty pathologists volunteered to use SNOP in their own laboratories for one year and report back their experience. The reports covered a quarter of a million surgical specimens and 6,000 autopsies. Ninety-four percent were pleased with SNOP and decided to use it in their laboratories. Over 500 other copies had been sent to selected pathologists and record librarians. Great numbers of suggestions, omissions and corrections were thus accumulated for processing. The many praises of the work were encouraging.

The need for a compendium with 95 percent of the more common diagnoses made in a pathology service of a general hospital was recognized. This was accomplished separately with the aid of 265 pathologists. This publication reduced the time of locating code numbers to a few seconds in the experience of most of the volunteers. Seventy-four percent felt that it was "useful" or "very useful." A few stated that it made the difference between using or discarding SNOP in their financially embarrassed laboratories.

CIOMS, WHO, ICD and ICDA

The urgent need for international agreement on medical nomenclature led the committee to a long series of lectures and exhibits in foreign countries. These were held at international pathology society meetings in Zurich and Moscow in 1962, Mexico City and San Salvador in 1963, London in 1964, Kyoto and Leyden in 1966, and Toulouse in 1967. It was necessary to turn down other requests for presentations because of lack of personal funds among committee members.

The Council on International Organizations of Medical Sciences (CIOMS) is composed of all international societies of the medical sciences except public health which is represented by the World Health Organization (WHO). CIOMS called a meeting of representatives of its ten international societies of the disciplines of anatomic and clinical pathology in Brussels in October 1965. After considerable discussion the representatives present unanimously approved a program for devloping an international nomenclature and code based on SNOP. The executive committee and later in 1968 in Paris, the General Assembly approved this with the stipulation that the pathologists' groups should develop and try out their fields of interest before the other specialties were involved in a Systematized Nomenclature of Medicine (SNOMed).

SNOMed

William McMenemey, neuropathologist of London was appointed chairman of the project. He started to organize his committee. A. P. Messerli, executive secretary of CIOMS sent a list of the international societies of pathology requesting a division of the pages of SNOP according to the areas of interest of the various societies. Suddenly Messerli was replaced in his position. Shortly thereafter McMenemey wrote that he could not get funds to proceed with meetings for his assignment.

It happens that CIOMS can barely exist on the dues of its members. WHO and UNESCO routinely provide funds for special projects which they must approve. WHO has a classification and coding system, the International Classsification of Diseases[5] (ICD). This publication is a most extensive collection of terms in clinical medicine including most of the specialties. It has been accepted and used successfully by the prin-

cipal health departments of the world for the statistical analysis of causes of death. WHO offered CIOMS financial aid to develop an International Nomenclature of Diseases (IND). A. G. T. Robb-Smith, Oxford professor of pathology and long-standing consultant in the development of ICD, was to become the chairman of this endeavor.

In his letters, Robb-Smith described SNOP with an obviously fixed mind and in an authoritative style. He insisted that Chandler-Smith's Natural Language computer storage system would cover the needs of pathology. Furthermore, there was nothing wrong with ICD as a storage and retrieval vehicle. Following a committee meeting in Florence, Italy, he proceeded to develop IND in the tradition of the Nomenclature of Disease of the Royal College of Physicians of London (1869 to 1957-7th ed.) In its prepublication "Computerized Drafts," it is a random collection of slightly over 1.000 morphological, functional and etiological terms with about 300 definitions and no code. Less than five percent of terms in the disciplines of medicine appear in the original trial publication. The book will be a badly needed and an important landmark when published. If it should ever cover the field of medical science and have an acceptable classification and code it would soon be in daily use in medical institutions throughout the modern world.

Since ICDA (Adapted)[6] the United States version of ICD has replaced SNDO in 90 percent of the hospitals in this country. A brief evaluation of both is indicated. ICD and its offspring ICDA had their basis of origin in the 1800's, originally designed for collecting public health statistics. Since 1949, there has been an all-out effort to add diagnostic terms from most fields of clinical medicine. The overloaded single four-digit field spilled out into "E", "N" and "Y" fields.

Briefly, if a neurosurgeon or pathologist wished a pinpoint storage of a case of meningioma in the corpus collosum or a tuberculoma in the left internal capsule it would be out of the question using the ICDs. If one wished to store the name of a single organism of a large unlisted group of bacteria or viruses it must be filed with "other bacteria." If the disease is in most specific sites of the body it must be filed as "other sites." The great majority of non-fatal diseases occur in groups with a single code number, thus the computer cannot print out a large percent of the single disease entities. The magnificent collection of diagnoses in ICD and ICDA must be restructured to meet the requirements of today's mechanical technology.

Computer Age

This is the computer age. Physicians must utilize this mechanical brain much more than they have to date. The computer can be trained or "structured" to store complete classifications with codes so that one need not code diagnoses to store them. The simply typed or spoken disease name or any of its synonyms will be stored and retrieved. Thus using SNOP one can retrieve complete discharge notes on patients including history, physical findings, symptoms, diagnoses, autopsy findings and eventually therapy, possibly using CPT of the AMA. Groups of patients with any single one of the listed features recorded may be retrieved. Eventually diagnostic and therapeutic aids will be available along with many other uses.

Selected Highlights of SNOP's Reception

Seminars, workshops, lectures and exhibits have been conducted annually at CAP-ASCP meetings in Chicago, New York, Miami and Seattle. Nine thousand copies of SNOP have been sold throughout much of the world. At the last of the workshops in Chicago, George E. Gantner, associate professor, medical examiner and computer expert of St. Louis, presented his publication, "Data Processing Methods for Diagnostic Codes—Systematized Nomenclature of Pathology." It covers the many uses of SNOP and is available at the CAP office at a nominal price. Recently Doctor Gantner has developed an Automatic Autopsy Protocol for Computer and a Compendium for Forensic Pathology using SNOP code. The former can completely replace the use of a medical secretary.

Virgil Slee of the Commission on Professional and Hospital Activities of Ann Arbor accepted SNOP on their computer to store pathologists' records from hundreds of hospitals throughout the country. The National Heart and Lung Institute of the Public Health Service and the International Society of Cardiology utilized SNOP code in their classifications.[7,8]

Within two months of our exhibit in Kyoto with the assistance of John W. Berg of the Na-

tional Cancer Institute, the Japanese pathologists were given permission to translate SNOP to Japanese using the SNOP code. They had finished the translation a year later and were storing all autopsy diagnoses from all parts of the nation on a computer in Tokyo.

Ronald S. Beckett, chief pathologist of the large (900 bed) Hartford General Hospital working with the chief record librarian, Jean A. Ryan, RRL, has published articles[9] and given lectures on the use of SNOP for record room computer storage of diagnoses in all specialties of medicine. They claim great success in using SNOP for three years and 300,000 discharge diagnoses using some 800 additional new terms for the entire field of clinical medicine. This work has led Roger Cote on the Faculty of Medicine at the University of Sherbrooke to translate SNOP into French and use it for central computer storage of general hospital records for 18 hospitals in Quebec.

Eric P. van der Esch of Wilhelmia Gasthuis, University of Amsterdam, writes that the pathologists of Holland have financed a project PALGA. This will translate the English of SNOP into the Dutch and Latin languages. This is planned to result in central computer storage of all autopsies performed in Holland when it is finished.

Following a recommendation to the publishing company by Professor H. Hemperl, Head of the Department of Pathology of the University of Venusberg in Bonn, to the publishing company, Springer-Verlag requested permission in 1968 to publish SNOP as a book in four languages—English, German, French and Italian. The Board of Governors of CAP, contrary to the wishes of the committee, refused to permit the use of English. The publisher dropped the project.

In the Department of Anatomical Pathology of the National Institutes of Health, Louis B. Thomas computerized 200,000 diagnostic terms from autopsies performed over the previous ten years. He experienced excellent retrieval of diagnostic information. Later with the assistance of Arnold Pratt, hospital discharge notes on patients' charts were computerized with success.

Of all the uses of SNOP, undoubtedly the most productive was that of Arnold W. Pratt, Director of Computer Research and Technology at the National Institutes of Health. Using SNOP and assisted by his staff of linguists over the past six years he has promoted the computerization of medicine more than any one individual. He has revealed the amazing complexity of the natural language of medicine as used by highly trained physicians.[10] The computer must be structured to receive these numerous expressions as synonyms of preferred terms. This new science of Computational Linguistics reached a peak of practical accomplishment with the machine translation from Russian into English. This work is referred to as the "IBM-Georgetown Experiment." It was recognized that the computer which has the capacity to handle symbols effectively can also treat words as symbols and language as a string of symbols. The jargon of this science is guaranteed to lose the uninitiated in seconds. For one thing, linguistic analysis reveals a mixture of Latin, Greek and English suffixes and prefixes are used frequently and interchangeably. There is also a heterogeneous linguistic origin found in single word forms and a veritable jumble of compound word forms used routinely by physicians. A few examples will illustrate this:

Semantically Equivalent Phrases

muscle atrophy
atrophy of muscle
atrophic muscle
muscular atrophy

parathyroid gland adenoma
parathyroid adenoma

congenital aortic stenosis
congenital stenosis of aorta

acute staphylococcus pneumonia
acute pneumonia due to staphylococcus

It becomes abundantly apparent that a natural language classification of medical terms is much more complicated than it was before January of 1965 when SNOP was written. Numerous synonyms must be added in all fields. Suffixes and prefixes may need inclusion. When this and more is accomplished, the computational linguists will be needed to structure the computer to automatically handle the language we unconsciously scramble.

Contacts with the American Medical Association have been continuous from the first meeting at the AFIP in 1958 when Mrs. Adelaide Hayden, Asst. Editor of SNDO was present. We assisted Burgess Gordon with his editing of the pathology

aspects of CMT. After a series of meetings in November 1964, Hugh H. Hussey, director of scientific activities of the AMA offered to store SNOP on their computer with the prospect of making additions and eventually automatically print out the second edition of SNOP on the computer which prints the JAMA and other journals. Unbeknown to the committee this was never accomplished. At present the matter of preparing a master nomenclature and code of clinical medicine using the assistance of the various national specialty societies is pending in the House of Delegates. The AMA is unquestionably the natural owner of a SNOMed—a computer language of medicine. The task of seeking out the terms for this publication can be accomplished without much difficulty from the extensive publications of the various specialties. How to get authoritative approval of the nomenclature and properly classify the terms will be more difficult.

Summary

I would like to end my presentation with a listing of the unique structure and exclusive features to be found in SNOMed. You can compare them with those of the ICDs, SNDO, CMIT and others. They include:

1. A classification and coding system of medical terms into their "medical parts of speech," i.e., Site, Morphology, Etiology, Physiology, Therapy and Diagnostic Procedures in the style found in SNOP.
2. A classification and code for practically all terms in all specialties of medicine for their routine clinical practice for a single central storage and retrieval department.
3. Numerical equivalents with equal recognition of each disease entity (mild or fatal), each anatomic site, each named morphologic change, each altered function and insofar as is practical each etiologic agent.
4. A hierarchal classification and code using the decimal system permits a flexible contraction of any part of the detailed lexicon.
5. The use of well organized and constructed compendiums that assist the general hospital as well as specialty institutions with an almost instantaneous code for 95 percent of their diagnoses.
6. There will be a coded classification of every anatomic site of practical importance to each of the various specialties of medicine.
7. The expert guidance and assistance of Arnold Pratt, M.D. and his computational linguists of Computer Research and Technology of NIH, plus his encoding instructions for the use of SNOP.
8. Probably the only complete single source of internationally (IND of CIOMS) and nationally (CMIT of AMA) approved preferred nomenclature at the time of publication.
9. The capability of receiving printouts of any requested set of clinical information from a computer encoded with the numerical indexes of SNOMed and the instructions of computational linguists with simple natural language storage (typing) eliminating hand coding.

But most thro' midnight streets I hear
How the youthful Harlot's curse
Blasts the new born Infant's tear,
And blights with plagues the Marriage hearse.*

*William Blake: London.

Legislation

Interim Committees Focus on Health Issues

THE COMMITTEE SYSTEM is the legislature's way of delegating responsibility and maintaining a continuous, smooth functioning operation in the face of manifold and complex problems. Not all legislative responsibility can be efficiently carried out by a legislative body acting as a whole nor can all issues be given in depth consideration during the 120 day regular biennial sessions. This has given rise to Permanent, Interim and Standing Committees. Standing Committees function through each legislative session. Permanent Committees and Commissions, as distinguished from those operating only during sessions or the interim between sessions, are established to deal with problems of a continuous and recurring nature.

Interim Committees and Commissions are designed to operate during the period between regular sessions of the legislature. Many Standing Committees are also activated during the interim period. These committees investigate and study various programs and policies which are expected to be the subject of legislation in the next session. Committees and subcommittees studying a variety of state concerns will be reporting their findings and making recommendations to the 1973 Legislature based on information obtained since the 1971 session.

This interim period has been shortened considerably by the length of the special session last year. However, several committees have been studying numerous health or medically related matters of importance to medicine during this period. This is not surprising as there were well over 300 health related bills introduced and considered by the 1971 Legislature. Attracting much public attention this year were interim hearings of a special House Subcommittee on Nursing Homes during which extensive testimony, both pro and con, was given regarding the quality of care in Minnesota nursing homes. This committee, chaired by Representative Gary Flakne of Minneapolis, also has been conducting on-site inspections of certain nursing homes to attempt to evaluate the need for special legislation in 1973. The Minnesota State Medical Association has assisted this committee by arranging for physicians, primarily from the MSMA Committee on Aging, to accompany the committee on their inspection tours. The Medical Education Subcommittee of the House Appropriation Committee has been especially active this interim. As medical education was heavily funded by the 1971 Legislature, progress reports are being made to this committee by administrators and directors of the various graduate and undergraduate programs in medical education. Presentations have been made to the committee regarding the new two-year Medical School at the University of Minnesota, Duluth, the newly funded four-year Medical School at Mayo, the expanded Medical School program at the U of M, and various graduate and undergraduate hospital based programs. The committee has been keenly interested in learning of the progress made in the training of family practitioners as these programs were given top priority last session. Committee members have generally reacted favorably to the progress reports given to date.

The Medical Education Committee has also scheduled hearings to study the adequacy or need for funding of nursing and other allied health education programs.

A special charge given the House Medical Education Subcommittee this interim was to attempt to resolve the interdisciplinary problems which arose last session over MSMA's Delegatory Bill and Comprehensive Health Planning proposal to certify allied health manpower through a health manpower commission.

The Health Subcommittee of the House Health Welfare and Corrections Committee has met a number of times this interim to discuss such matters as health maintenance organizations, comprehensive health planning, the State Board of Health, certification of need legislation and various other matters relating to health delivery. Governmental reorganization of the occupational and professional licensing boards has been the subject of much staff research and committee deliberation, especially on the Senate side of the Capitol.

The Senate Civil Administration Subcommittee on Health Services and Consumer Affairs and the Senate Committee on Health and Welfare have listened to departmental and research staff presentations suggesting an overhaul of the independent licensing board structure especially in the area of the health professions. Legislation may be recommended for 1973 by these interim committees calling for consumer representation, central housing

and administrative services for the licensing boards and possibly a superboard which would license all the health professions.

The activities and organization of the State Board of Health have also come into sharp focus during this interim period. Dr. Warren Lawson, Executive Secretary of the State Board of Health, has presented detailed testimony to interim committees on more than one occasion. Historically a target for governmental reorganization, the State Board of Health has been provided ample opportunity in the interim hearings to advise the legislators of its activities and operations.

Also of interest to medicine is a special Subcommittee on Alcohol and Drug Laws of the House Judiciary Committee which is considering the advisability of recodification of the numerous State laws relating to alcohol and drugs. Input from the MSMA Subcommittee on Alcoholism and Drug Abuse will be made before this interim committee formulates its recommendations. A Subcommittee of the Senate Judiciary Committee is considering a proposal for a new professional corporation act to replace the separate acts now existing for each separate profession including medicine.

In the area of welfare the 1971 Legislature charged the Commissioner of Public Welfare with developing a comprehensive plan for the future use of State institutions, to make recommendations regarding community based programs and generally to review and revamp Department of Public Welfare programs relating to mental illness, retardation and inebriety. As a result of this charge Welfare Subcommittees in both the Senate and House have been appraised of progress in this area by personnel from the Department of Public Welfare. A final plan will presumably be forthcoming this year.

Coming under close scrutiny by legislative interim committees in the Senate and House is the welfare appropriation for medical assistance. While testimony on nursing home rates have monopolized much of the committees' time, other components of the medical assistance dollar have also been discussed including proposals to curb presumed overutilization of medical services.

The aforementioned areas of interest to medicine are by no means inclusive of all the health related subjects coming under the purview of the interim committees during this seemingly brief interval between sessions. It should be apparent to the reader though that the legislative responsibility of the MSMA is an on-going one which does not end with each session's adjournment. Interim committee hearings are audited regularly by MSMA representatives and appropriate testimony given when indicated. The legislative proposals embodied in these interim committee reports are obviously only recommendations. Often these interim reports fail to see the light of a legislative day particularly if its interim advocate(s) are not reelected. Chances are though that most interim recommendations will be considered by some legislators to be worthy of introduction in bill form making it all the more important for medicine to assist and participate in the legislative process between, as well as during, each session.

A Strange Language

A Lawless Language is English:
The plural of box is boxes,
But more than one ox is not oxes.
One fowl's a goose, more are two geese,
But more than one mouse is certainly not meece.
On the contrary for mouse, the plural is mice,
While the plural for house is never hice!
If more than one man is always men,
The plural of pan should then be pen?
One may be that and two may be those,
But the plural of hat is surely not hose!
Masculine pronouns are he, his and him.
Imagine the feminines she, shis and shim!
The English language, I think you'll agree,
Is as strange a language as ever could be.

140/90 is normal blood pressure...or is it?

An extensive study based on nearly 4 million life insurance policies suggests that a blood pressure reading of 140/90 requires close medical supervision.

Study Findings. Twelve years ago the Society of Actuaries reported on an extensive study based on the lives and deaths represented by almost 1 million life insurance policies. From this vast survey—"The Build and Blood Pressure Study"[1]—insurance experts concluded that:

Blood pressure above 140/90 is accompanied by increased morbidity and requires close medical attention.

Even small increments in either systolic or diastolic blood pressure progressively and steeply shorten life expectancy.

Other Studies. Studies conducted with large numbers of patients since that time have echoed the above findings. Two studies published in 1970—the VA Cooperative Study Group on "Effects of Treatment on Morbidity in Hypertension"[2] and the "Framingham Study"[3]—suggest that treatment of even mild hypertension may, over time, offer significant benefits to the patient.

Another Point of View. Although a growing body of studies suggests that treatment of mild hypertension is warranted, medical opinion is not unanimous. Some clinicians recommend that drug treatment for mild hypertension be reserved for patients with additional risk factors such as smoking, high cholesterol

levels, heart or kidney involvement, or a family history of vascular disease. Dr. Walter M. Kirkendall stated this position in his recent paper "What's With Hypertension These Days?"[4] Discussing the management of hypertension in patients with a sustained diastolic pressure up to 100 mm Hg, he said: "Generally, I do not recommend antihypertensive therapy unless patient's blood pressure approaches the upper limit for the group and a number of adverse factors exist, such as male sex, family history of vascular disease, youth, evidence of heart or kidney involvement."

Drug Therapy for Hypertension. Although opinion varies on when to start drug therapy for mild hypertension, many physicians agree that treatment should start with a thiazide diuretic such as HydroDIURIL. For the adult patient, the usual starting dosage is 50 mg b.i.d. Dosage adjustments are recommended as the patient responds to treatment. The patient whose therapy begins with HydroDIURIL frequently can continue to benefit from it, because HydroDIURIL usually maintains its antihypertensive effect even when therapy is prolonged.

4. Kirkendall, Walter M.: "What's With Hypertension These Days?" Consultant, Jan. 1971.

25- and 50-mg tablets

HydroDIURIL®

(Hydrochlorothiazide|MSD)

Therapy to Start With

Drug Therapy for Hypertension. Although opinion varies on when to start drug therapy for mild hypertension, many physicians agree that treatment should start with a thiazide diuretic such as HydroDIURIL. For the adult patient, the usual starting dosage is 50 mg b.i.d. Dosage adjustments are recommended as the patient responds to treatment. The patient whose therapy begins with HydroDIURIL frequently can continue to benefit from it, because HydroDIURIL usually maintains its antihypertensive effect even when therapy is prolonged.

CONTRAINDICATIONS: Anuria; increasing azotemia and oliguria during treatment of severe progressive renal disease. Known sensitivity to this compound. Nursing mothers; if use of drug is deemed essential, patient should stop nursing.

WARNINGS: May precipitate or increase azotemia. Use special caution in impaired renal function to avoid cumulative or toxic effects. Minor alterations of fluid and electrolyte balance may precipitate coma in hepatic cirrhosis.

When used with other antihypertensive drugs, careful observation for changes in blood pressure must be made, especially during initial therapy. Dosage of other antihypertensive agents, especially ganglion blockers, must be reduced by at least 50% because HydroDIURIL potentiates their action.

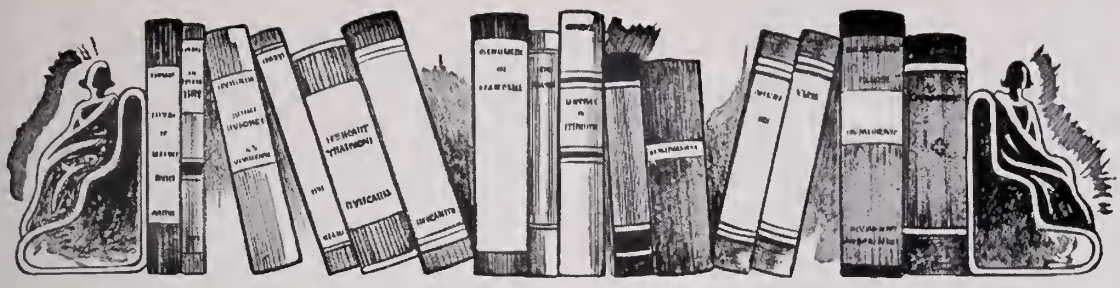
Stenosis and ulceration of the small bowel causing obstruction, hemorrhage, and perforation have been reported with the use of enteric-coated potassium tablets, either alone or with nonenteric-coated thiazides. Surgery was frequently required, and deaths have occurred. Such formulations should be used only when indicated and when dietary supplementation is impractical. Discontinue immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occurs.

Thiazides cross placenta and appear in cord blood. In women of childbearing age, potential benefits must be weighed against possible hazards to fetus, such as fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult.

The possibility of sensitivity reactions should be considered in patients with a history of allergy or bronchial asthma. The possibility of exacerbation or activation of systemic lupus erythematosus has been reported for sulfonamide derivatives, including thiazides.

PRECAUTIONS: Check for signs of fluid and electrolyte imbalance, particularly if vomiting is excessive or patient is receiving parenteral fluids. Warning signs, irrespective of cause, are dryness of mouth, thirst, weakness, lethargy, drowsiness, restlessness, muscle pains or cramps, muscular fatigue, hypotension, oliguria, tachycardia, and gastrointestinal disturbances. Hypokalemia may develop (especially with brisk diuresis) in severe cirrhosis; with concomitant steroid or ACTH therapy; or with inadequate electrolyte intake. Digitalis therapy may exaggerate metabolic effects of hypokalemia, especially with reference to myocardial activity. Hypokalemia may be avoided r treated by use of potassium chloride or giving fo with a high potassium content. Similarly, any chlor deficit may be corrected by use of ammonium chlor (except in patients with hepatic disease) and larg prevented by a near normal salt intake. Hypochlorer alkalosis occurs infrequently and is rarely severe. severely edematous patients with congestive failure renal disease, a low salt syndrome may occur if diet salt is unduly restricted, especially during hot weath

Thiazides may increase responsiveness to tubo rarine. The antihypertensive effect of the drug may enhanced in the postsympathectomy patient. Arte responsiveness to norepinephrine is decreased, nec sitating care in surgical patients. Discontinue drug hours before elective surgery. Orthostatic hypotensi may occur and may be potentiated by alcohol, barb urates, or narcotics.



Pathological changes in the parathyroid glands w hypercalcemia and hypophosphatemia have been se in a few patients on prolonged thiazide therapy. T effect of discontinuing thiazide therapy on serum c cium and phosphorus levels may be helpful in asse ing the need for parathyroid surgery in such patier Parathyroidectomy has elicited subjective clinical i provement in most patients, but has no effect hypertension. Thiazide therapy may be resumed af surgery.

Use cautiously in hyperuricemic or gouty patien gout may be precipitated. May affect insulin requi ments in diabetics; may induce hyperglycemia a glycosuria in latent diabetics.

ADVERSE REACTIONS: Rare reactions inclu thrombocytopenia, leukopenia, agranulocytosis, apl tic anemia, cholestasis, and pericholangiolitic hepatit Nausea, vomiting, diarrhea, dizziness, vertigo, par thesias, transient blurred vision, sialadenitis, purpu rash, urticaria, photosensitivity, or other hypersen tivity reactions may occur. Cutaneous vasculitis p cipitated by thiazide diuretics has been reported elderly patients on repeated and continuing expos to several drugs. Scattered reports have link thiazides to pancreatitis, xanthopsia, neonatal thro bocytopenia, and neonatal jaundice. When adve reactions are moderate or severe, the dosage thiazides should be reduced or therapy withdraw

Book Reviews

CURRENT DIAGNOSIS AND TREATMENT, 1972. Krupp, M.A., and Chatton, M. J. Lange Medical Publications, Los Altos, Ca., 1972. 962 pages. Paper back $11.00.

This work was first published in 1962 with re-issue of copyrights and presumably new editions approximately yearly. The first item of business perusing a re-issue is to determine whether the recent copyright, 1971, and the 1972 on the cover indicate that the material is updated. There are indeed many references to 1970 and 1971 publications indicating immediacy of the material. I prefer to see the references keyed specifically to statements instead of being simply listed generally at the end of chapters. The sections fulfill the purpose of a textbook in medicine outlining the important features of disease, their diagnosis and treatment, and listing significant references for further reading. There are 34 collaborators mostly from the faculties of Stanford and San Francisco.

PEDIATRIC THERAPY, 4th Edition. H. C. Shirkey, Editor, C. V. Mosby Company, Saint Louis, 1972, $34.50.

This volume is a welcome review of the 1968 date line 3rd Edition. It stands to become as useful to the family practitioner and pediatrician as the Bible is to the clergyman.

This formidable compendium by todays experts on their recommendations for specific therapy for specific disease deserves consultation when an unfamiliar disease problem occurs in a pediatric patient.

This book will also provide a useful consultation regarding therapy for familiar conditions to discover better ways to approach an old problem or confirm a present regular prescription. *Pediatric Therapy,* 4th Edition is a recommended best buy.

Warren J. Warwick, M.D.
Minneapolis, Minnesota

INSTRUCTIONAL COURSE LECTURES. The American Academy of Orthopedic Surgeons. Vol. xx, 1971. Publishers: C. V. Mosby Co., St. Louis, Missouri.

As in past volumes, the 1971 *Instructional Course Lectures* provides an excellent review of selected topics related to orthopedic surgery by leading authorities.

Especially well done are sections dealing with cerebral palsy, with particular emphasis on the lower extremity, and the discussion of intertrochanteric osteotomy of the hip for degenerative joint disease by Karl H. Mueller.

Other fine contributions include surgical anatomy of the knee and a section on lower extremity bracing. Arthur J. Helfet has written a section which nicely describes the early changes of osteoarthritis of the knee. The author's discussion of surgery for this condition is quite superficial and should be better covered in future volumes.

The use of medullary fixation as a primary treatment in fractures of forearm bones is recommended in a section written by Fred T. Sage. However the use of compression plate fixation for most of these fractures appears to be gaining wider acceptance as results of treatment are accumulated.

This is an excellent volume on many timely subjects and is recommended for all of those interested in orthopedics.

Lee C. Detenbeck, M.D.
Rochester, Minnesota

APPROACH TO THE MEDICAL CARE OF THE SICK NEWBORN, by Sophie H. Pierog, M.D., and Angelo Ferrara, M.D., the C. V. Mosby Company, St. Louis, 1971: 292 pages; Price $11.50.

The subspecialty of pediatricts called *neonatology* is so new that it is peopled almost entirely by physicians who have learned from each other and from their own experiences. What they have learned in the last decade they are now teaching to tomorrow's innovators in a few major centers. Most of the information needed for the care of the sick newborn thus is available only in the pages of scattered journals, limited circulation manuals for nurses and residents and in the minds of the neonatologists themselves.

Into this little book, two obviously experienced and thoughtful pediatricians have poured a great deal of valuable information. The material is presented in short, pithy chapters in which good use is made of charts, flow diagrams, tables, and well organized prose. Line drawings are used to advantage as chapter headings and to illustrate such diverse subjects as gestational age and prevention of maternal Rh sensitization.

The book opens with a short initial section on the organization of newborn services and closes with a series of appendices which include details on procedures (such as umbilical vessel cannulation and blood sampling microtechniques) infant drug dosages, formula contents, and normal laboratory values. The rest of the book covers in a concise, readable way most of the problems—physical, physiological, sociological, and economic—that the physician, the infant, the infant's parents, and the community have to face.

This book should be of value to pediatric and obstetric residents and to nursing personnel in newborn intensive care units. More important, however, would be its availability to any physician who cares for newborns in the community hospital away from a specialized neonatal care unit. Two evenings spent perusing these pages will pay off in better care for the normal newborn and greater salvage of the sick newborn whether transferred to a specialized center or not.

Charles W. Jarvis, M.D.
St. Paul, Minnesota

Hexachlorophene Merry-Go-Round

The U.S. Food and Drug Administration is developing reservations concerning the safety of hexachlorophene following reports that untoward results have been observed in rats and monkeys previously exposed to the drug in abnormally large quantities.

Such reports should be interpreted with great caution. In the case of the experimental rats the animals were fed hexachlorophene. No one has ever recommended the oral route for human beings. In the case of the baby monkeys, one authority estimates that from four to six times greater amounts were used than is customary for humans.

The FDA, in announcing restrictions on the use of hexachlorophene, stated that there has been no evidence of harm to humans when it is used as recommended. One of the standard cautions has been for careful clear water rinsing after bathing.

The head of the Canadian Health Department Food and Drug Directorate said that the bacteria-destroying chemical has been used without ill effect for more than 20 years to bathe newborn infants. Other than advising physicians to ensure careful compliance with instructions for proper use the Canadian said further that his committee would monitor further developments and would not change policy until results of experiments were known.

The backlash effect in the United States is already evident. There are reports of nurseries wherein epidemics of staphylococcal skin disease have developed following discontinuance of hexachlorophene bathing.

It doesn't take a very long memory to go back to prehexachlorophene days when such epidemics were stubborn and dangerous—sometimes being associated with fatalities.

Further animal experimental studies are being done. In view of the fact that no human toxicity under normal use conditions has ever been reported it would seem to be wise to await the additional information which will be provided.

March 1972 issue, Indiana Med. Assn. Permission to copy granted by Frank B. Ramsey, M.D.

Calm as a clock your knowing hand directs,
Rhei, jalapae ana grana sex,
Or trace on some tender missive's back,
Scrupulos duos pulveris ipecac;
And leaves your patient to his qualms and gripes,
Cool as a sportsman banging at his snipes.
But change the tune, the person, and the place,
And be yourself "the interesting case,"
You'll gain some knowledge which it's well to learn;
In future practice it may serve your turn.
Leeches, for instance—pleasing creatures quite;
Try them—and bless you—don't you find they bite?*

*Oliver Wendell Holmes, Sr.: The Morning Visit, 1849.

A MINNPAC INVITATION

The MINNESOTA MEDICAL POLITICAL ACTION COMMITTEE invites you to support the singularly most effective means available to make medicine's voice heard in the political arena—MINNPAC/AMPAC.

Join MINNPAC today. Participate in the political and governmental process which will ultimately determine how the practice of medicine will be structured during this decade. Your $25.00 includes both MINNPAC and AMPAC dues and will be used to assist in electing responsible men and women in both parties to the State Legislature and to Congress. The MINNPAC Board of Directors is charged with the responsibility of urging physicians and their wives to become actively involved in the support of candidates and the party of their choice. *YOUR* help is needed *NOW!* Complete the application form or merely send your $25.00 check to: MINNPAC, Metro Medical Building, 825 South 8th Street, Room 503, Minneapolis 55404.
P.S. Those of you who have already sent your check—*Thank You!*

☐ Please bill me $25.00 for my annual membership in MINNPAC and AMPAC.
☐ Membership contribution is enclosed.

Section 1 of Two Sections

The negative power of undue anxiety
in congestive heart failure...
This man thinks he can no longe
take breathing for granted.

Typical of many patients with congestive heart failure, he also suffers from severe anxiety, a psychic factor that may influence the character and degree of his symptoms, such as dyspnea. His apprehension may also deprive him of the emotional calm so important in maintenance therapy.

Aid in rehabilitation

Specific medical and environmental measures are often enhanced by the antianxiety action of adjunctive Libritabs (chlordiazepoxide). Libritabs can also facilitate treatment of the tense convalescent patient until antianxiety therapy is no longer required. Whereas in geriatrics the *usual daily dosage* is 5 mg two to four times daily, the *initial dosage* in elderly and debilitated patients should be limited to 10 mg or less per day, adjusting as needed and tolerated.

Concomitant use with primary agents

Libritabs is used concomitantly with certain specific medications of other classes of drugs, such as cardiac glycosides, diuretics, antihypertensives, vasodilators and oral anticoagulants, whenever excessive anxiety or emotional tension adversely affects the clinical condition or response to therapy. Although clinical studies have not established a cause and effect relationship, physicians should be aware that variable effects on blood coagulation have been reported very rarely in patients receiving oral anticoagulants and chlordiazepoxide HCl.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Indicated when anxiety, tension and apprehension are significant components of the clinical profile.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

Prompt relief of pain is a lot of what the practice of medicine is all about... East or West.

In much of the Far East, the analgesic efficacy of Empirin® Compound with Codeine would probably be measured against acupuncture, an ancient and traditional therapeutic system.

In America, codeine sets such a high standard for oral analgesia, that it has become a criterion in terms of which other major oral analgesics are most often measured.

Synthetic and other oral analgesics may offer some of the properties of codeine, but not one can provide both its benefits and potency. And codeine provides an antitussive bonus.

Empirin Compound with Codeine is the most widely used, and probably the most pharmaceutically elegant analgesic preparation providing codeine. It's the time-tested combination for predictable pain relief . . . whether the pain is visceral or musculoskeletal; acute or chronic.

New prescription flexibility. At your discretion, and where state law permits, a prescription for Empirin Compound with Codeine may now be refilled up to five times in six months.

Empirin Compound with Codeine No. 3 contains codeine phosphate (32.4 mg.) gr. ½. No. 4 contains codeine phosphate* (64.8 mg.) gr. 1. *(Warning—may be habit-forming.) Each tablet also contains: aspirin gr. 3½, phenacetin gr. 2½, caffeine gr. ½. Bottles of 100 and 1000.*

But for relief of Western pain

MINNESOTA MEDICAL POLITICAL ACTION COMMITTEE

A MINNPAC INVITATION

The MINNESOTA MEDICAL POLITICAL ACTION COMMITTEE invites you to support the singularly most effective means available to make medicine's voice heard in the political arena—MINNPAC/AMPAC.

Join MINNPAC today. Participate in the political and governmental process which will ultimately determine how the practice of medicine will be structured during this decade. Your $25.00 includes both MINNPAC and AMPAC dues and will be used to assist in electing responsible men and women in both parties to the State Legislature and to Congress. The MINNPAC Board of Directors is charged with the responsibility of urging physicians and their wives to become actively involved in the support of candidates and the party of their choice. *YOUR* help is needed *NOW!* Complete the application form or merely send your $25.00 check to: MINNPAC, Metro Medical Building, 825 South 8th Street, Room 503, Minneapolis 55404.
P.S. Those of you who have already sent your check—*Thank You!*

☐ Please bill me $25.00 for my annual membership in MINNPAC and AMPAC.
☐ Membership contribution is enclosed.

BECAUSE ALLERGIES ARE A YEAR-ROUND THING.

That's why you need to remember Novahistine LP.
A liquid formula that relieves nasal congestion,
And it's available only at your

NOVAHISTINE® LP

DOW PHARMACEUTICALS

Why send him to the islets of Langerhans?

Since sulfonylureas promote the release of insulin which is lipogenic and helps transport glucose into adipose tissue...

And since many overweight patients already have normal or high levels of endogenous insulin, why not consider DBI-TD?

It lowers blood sugar without stimulating insulin secretion from the pancreas. And this may be important to the dieting diabetic.

In adult-onset, nonketotic diabetics uncontrolled by diet alone...

DBI-TD® **Geigy**
phenformin HCl

lowers blood sugar without raising blood insulin.

DBI® phenformin HCl
Tablets of 25 mg.
DBI-TD® phenformin HCl
Capsules of 50 and 100 mg.

Indications: Stable adult diabetes mellitus; sulfonylurea failures, primary and secondary; adjunct to insulin therapy of unstable diabetes mellitus.
Contraindications: Diabetes mellitus that can be regulated by diet alone; juvenile diabetes mellitus that is uncomplicated and well regulated on insulin; acute complications of diabetes mellitus (metabolic acidosis, coma, infection, gangrene); during or immediately after surgery where insulin is indispensable; severe hepatic disease; renal disease with uremia; cardiovascular collapse (shock); after disease states associated with hypoglycemia.
Warnings: Use during pregnancy is to be avoided.
Precautions: 1. *Starvation Ketosis:* This must be differentiated from "insulin lack" ketosis and is characterized by ketonuria which, in spite of relatively normal blood and urine sugar, may result from excessive phenformin therapy, excessive insulin reduction, or insufficient carbohydrate intake. Adjust insulin dosage, lower phenformin dosage, or supply carbohydrates to alleviate this state. **Do not give insulin without first checking blood and urine sugar.**
2. *Lactic Acidosis:* This drug is not recommended in the presence of azotemia or in any clinical situation that predisposes to sustained hypotension that could lead to lactic acidosis. To differentiate lactic acidosis from ketoacidosis, periodic determinations of ketones in the blood and urine should be made in diabetics previously stabilized on phenformin, or phenformin and insulin, who have become unstable. If electrolyte imbalance is suspected, periodic determinations should also be made of electrolytes, pH, and the lactate-pyruvate ratio. The drug should be withdrawn and insulin, when required, and other corrective measures instituted immediately upon the appearance of any metabolic acidosis.
3. *Hypoglycemia:* Although hypoglycemic reactions are rare when phenformin is used alone, every precaution should be observed during the dosage adjustment period particularly when insulin or a sulfonylurea has been given in combination with phenformin.
Adverse Reactions: Principally gastrointestinal; unpleasant metallic taste, continuing to anorexia, nausea and, less frequently, vomiting and diarrhea. Reduce dosage at first sign of these symptoms. In case of vomiting, the drug should be immediately withdrawn. Although rare, urticaria has been reported, as have gastrointestinal symptoms such as anorexia, nausea and vomiting following excessive alcohol intake.

President's Letter

Change

THE MINNESOTA STATE MEDICAL ASSOCIATION'S 119th Annual Convention has passed into history. One-fourth of our membership registered and participated in the scientific and business sessions. This is encouraging because the Minnesota State Medical Association can be representative of only those physicians who wish to express their views and can enhance the knowledge of only those who avail themselves of the opportunities to learn. Change is occurring. The scientific assembly had a new format and was well accepted. The Permanent Evaluation Committee suggested changes that the delegates implemented and is considering others. The House of Delegates has endorsed the principle of open elections and directed the formation of an Ad Hoc Abortion Study Committee, as well as directing new and renewed activity toward many of our scientific and non-scientific committees.

There was one surprise, a disappointing one. Most physicians I know feel that the AMA needs to change, but the AMA's Long Range Planning and Development Council heard only eighteen witnesses. The Council assembled its members from all corners of the nation on its own initiative, it was not directed to do so. Granted the site chosen by the AMA was removed from the main convention proceedings, the proceedings were often closer to a debate than an information gathering forum, and the original invitation was too easily interpreted as overly restrictive in what testimony would be heard, but after years in "organized medicine" and one of your delegates to the AMA, I was surprised to find so few who actually availed themselves of this opportunity to present their feelings about the AMA and what course it should follow in the future. The Council on Long Range Planning and Development should be commended for its appearance at our state meeting. Their presence denotes interest and willingness to change on the part of AMA. It is my sincere desire that you will share with your officers and councilors your feelings about the AMA *Your* AMA delegation would like to accurately represent you at future national conventions.

Two more changes. First, kudos for outstanding performance during his year as president to my dear friend, Robert T. Kelly. Peace and more time for your family, Bob. Secondly a welcome to John J. Regan, president-elect. I look forward to our association in the coming years.

"Cholangiolitic" Hepatitis and Cirrhosis ("Primary Biliary" Cirrhosis)

A Brief Review with Special Reference to Atypical Cases

GENE HARTMANN, M.D. AND C. J. WATSON, M.D., Ph.D.*

AHRENS AND CO-WORKERS[1] in their well known paper on "primary biliary" cirrhosis, credit Murchison with the first description of a case in 1869. It is interesting that Murchison's case was listed as "alcoholic cirrhosis." Hanot in 1875 described cases of "hypertrophic cirrhosis with chronic jaundice,"[2] also emphasizing lack of ascites and frequency of pruritus. These cases were very similar clinically and in gross pathologic terms to what today is commonly called "primary biliary" cirrhosis. Xanthomatosis has often been associated with this type of cirrhosis, and for a time Thannhauser and co-workers[3] believed that intrahepatic xanthomata were the cause of an obstructive biliary cirrhosis. Yet cases in which this sequence might be assumed, are rare. Also, there have been many instances in which a primary biliary obstruction such as stone, stricture, or cancer, has caused development of xanthomata as a result of the secondary hyperlipemia.[1] Ahrens[1] emphasized that many cases of "primary biliary" cirrhosis have been described both with and without xanthomatosis. Recent reviews[4-6] are in accord.

Clinical Features

Although an insidious onset of jaundice and pruritus is common, there are some remarkable variations in the clinical picture. The patient may be completely asymptomatic, or complain of nothing more than itching and/or darkening (melanosis) of the skin, even without jaundice. Less commonly, fatigue, weakness, loss of weight and loose stools are the presenting complaints. Abdominal pain, at times simulating biliary colic, may occur. In exceptional cases a history of exposure to chemicals or an earlier attack of hepatitis is noted. Females are affected much more often than males, and more frequently in middle age.[1,4]

The physical findings vary with the evolution of the disease. The liver is invariably palpable, often markedly enlarged and usually not tender. Evidence of pruritus is common. Jaundice is usual but variable and xanthomata are often encountered. Quite frequently there is prominent darkening of the skin, at times constituting the patient's chief complaint. This is generally believed to represent a melanosis,[1] though it has not been explained. Spider nevi are usually not as prominent as in Laennec's cirrhosis.

Laboratory Findings

Of the laboratory findings the most consistent and at times the only abnormality is an elevated serum alkaline phosphatase. When pruritus is present this is accompanied by marked increases of serum bile acids, particularly the trihydroxycholanic type.[7] The serum cholesterol,[4,8] mainly the esterified fraction, as well as phospholipids and total lipids[9] are characteristically increased and the greater the increase the more likely the appearance of xanthomata. The α_2[9] and β globulins[4] are likewise increased with the hyperlipidemia. Highly significant increases of IgM and antimitochondrial antibodies are rather characteristic.[9-11] The serum albumin usually remains at a relatively normal level for years. This together with the increased serum cholesterol bespeaks a relatively normal hepatocellular function. Late in the course of the disease, often only after years of chronic jaundice and pruritus, hepatocellular function fails progressively and the clinical picture may then resemble a more ordinary type of cirrhosis. In this late stage ascites may appear,

*University of Minnesota Medical Research Unit, Northwestern Hospital, Minneapolis, Minnesota 55407. Aided by a grant from Mr. & Mrs. D. E. Mudgett.
Address for proofs: Dr. C. J. Watson, Northwestern Hospital, Minneapolis, Minnesota 55407.

but even in its absence esophageal varices may bleed and cause death.

Terminology and Pathologic Classification

The designation "primary biliary" cirrhosis was introduced by Dauphinee and Sinclair in 1949[12] and championed in the following year by Ahrens and co-workers.[1] Though widely used, the term has not been acceptable to many students of liver disease, as cirrhosis is preceded by a protracted form of hepatitis. Other designations include "chronic nonsuppurative destructive cholangitis,"[13] "chronic intrahepatic obstructive jaundice,"[5] "nonobstructive cholangitic biliary cirrhosis,"[14] "chronic intrahepatic obliterating cholangitis,"[15] and "cholangiolotic"[16] or "cholangiotoxic" cirrhosis.[16] The term "pericholangiolitic" has also been used.[6,18,19] Injury, destruction or lysis of the smaller biliary channels are suggested in these terms. They were implicit in the designation "cholangiolitic" as used in 1946 by Watson and Hoffbauer,[17] for this form of cirrhosis, as well as its preceding hepatitis. The term "cholangiole" is used arbitrarily to include the ampullae of the bile capillaries (canal of Hering) as well as primary and interlobular bile ductules. At the time of their description, Watson and Hoffbauer[17] were more concerned with functional than anatomic considerations and the lack of definite histologic criteria no doubt accounts for failure of the term "cholangiolitic" to gain more widespread acceptance. Rössle[16] had used the term "cholangiolotic" for such cases, possibly in analogy with "nephrotic," to avoid implication of an inflammatory in contrast with a metabolic process. However, the term "cholangiolitic" appears justified in view of the evidence of a preliminary hepatitis (portal cellular exudate), the marked cholangiolysis and the disappearance of cholangioles. The term was later validated in the recognition by MacMahon[18,19] and others[4,6,13,20] that cholangiolysis is characteristic and evidently a basic phenomenon of the disease together with the clear evidence of chronic hepatitis which precedes the cirrhosis. The early abnormality and progressive disappearance of primary bile ducts in the portal spaces has become widely accepted as a histologic criterion for the diagnosis of "cholangiolitic" or "primary biliary" cirrhosis.

Case Reports

We have recently studied two cases* with the histologic diagnosis of hepatitis and cirrhosis ("primary biliary" cirrhosis). Their chemical and immunologic findings were quite atypical.

Case 1

A 70-year-old white female was first seen on August 11, 1970, with nausea, vomiting, and right lower abdominal pain radiating to the right flank. Her past history included cholelithiasis and mild episodes of cholecystitis. There had been no jaundice or pruritus. Physicial examination revealed a number of spider nevi and hepatosplenomegaly. The patient underwent a laparotomy for bowel adhesions. The liver was noted to be large and diffusely nodular. The patient was discharged after a few days but readmitted on November 29, 1970 for failure to regain strength. On December 11, 1970, a second laparotomy was done to determine the status of her biliary tract. The gallbladder was

*We are grateful to the attending physicians, Drs. Robert Scott and James Myhre, for permission to report Cases 1 and 2 respectively.

TABLE 1
Essential Laboratory Data in Case 1, Female, 70, 1970-71

Serum (see Normal Range, Table 2)	8/11/70	11/30/70	1/11/71	3/16/71
Bilirubin (mg%)				
Prompt direct	0.9	0.2	1.2	0.4
Total	1.6	0.8	2.5	1.5
Cholesterol (mg%)		176	185	246
Triglycerides (mg%)				55
Bile Acids (mg%)				
Trihydroxy			2.1	
Dihydroxy			0.8	
Alkaline Phosphatase, I.U.	490	425	520	259
SGOT (units)	79	94	96	84
SGPT (units)		22	38	16
Albumin (gm%)	3.4	3.2	3.0	3.4
α_1 globulin (gm%)		0.2		
α_2 globulin (gm%)		1.4	1.4	
β globulin (gm%)		1.1		
γ globulin (gm%)		1.8		

Addition data: (1/11/71) Antimitochondrial antibody titer 1:10; (11/30/70) BSP retention 14%, 45' after after 5 mg/kilo; prothrombin time 14.2/12.1; cephalin chol. flocculation 4+; thymol turbidity 11 units; FANA, latex fixation, Australia antigen, all negative; normal amounts of IgA, IgG, and IgM, on immunoelectrophoresis.

removed. There was chronic cholecystitis and cholelithiasis. The common duct was slightly thickened but not dilated, containing several 1 mm stones. T-tube drainage was instituted and continued until January 19, 1971. A wedge biopsy of the liver, on microscopic examination (Figure 1)* revealed: (1) marked sparsity of portal biliary radicles; (2) nodular cirrhosis; (3) occasional epitheloid cell granulomas; (4) prominent portal lymphocytic exudate, and (5) evidence of mild cholestasis, i.e., bilirubin staining of cells and occasional bile thrombi. The pathologist† stated that the histologic picture, especially the evidence of cholangiolysis, was most compatible with "primary biliary cirrhosis," rather than a secondary biliary cirrhosis in which ductular proliferation is prominent. The laboratory data, as shown in Table 1, were discordant with the histologic diagnosis except for a striking increase in alkaline phosphatase. The serum bilirubin was moderately increased and remained elevated two months after the second laparotomy. The serum cholesterol, antimitochondrial antibody, and immunoglobulins were normal. The serum bile acids were normal in accord with the absence of pruritus.

*We are indebted to Dr. N. Kostich, pathologist, for the microphotographs of Figures 1 and 2.

†We are indebted to Dr. Fred Lott for this report.

Fig. 1—Liver biopsy section from Case 1. Hematoxylin and eosin, X 100. Chronic hepatitis-cirrhosis, with marked paucity of portal biliary radicles.

Case 2

A 59-year-old white female was found on a routine office visit to have an elevated erythrocyte sedimentation rate and an abnormal BSP retention. The patient denied any physical complaints. Her past medical and family history was noncontributory, except that the patient admitted to five or six cocktails per day. There was no known exposure to hepatitis and no history of transfusions or needle puncture. Physical examination revealed a multilobular thyroid, punctate palmar erythema and palpable, slightly enlarged spleen and liver. The remainder of the examination was essentially normal.

Laboratory data (Table 2) revealed a striking increase of serum alkaline phosphatase, with elevated serum bilirubin, SGOT, increased α_2 and γ globulins, cholesteral and BSP retention. The antimitochondrial antibody and FANA (fluorescent antinuclear antibody) were not significantly increased, nevertheless IgM was at least two and a half times normal. An upper gastrointestinal x-ray showed a pedunculated mass arising from the lesser curvature of the stomach. At operation the gastric tumor was removed, proving to be an inflammatory fibroid of the stomach. An operative cholangiogram and wedge liver biopsy were done. The former was normal and palpation of the common duct revealed no

Fig. 2—Liver biopsy section from Case 2. Hematoxylin and eosin, X 100. Chronic hepatitis, paucity of bile ductules; epithelioid cell granuloma around damaged small bile duct.

TABLE 2
Essential Laboratory Data in Case 2, Female, 59, 1971

Serum	Normal Range	6/22	6/24	6/25	6/26	7/2
Bilirubin (mg%)						
Prompt direct	<0.3	1.9			1.0	1.9
Total	<1.5	3.0			2.1	3.0
Cholesterol, total (mg%)	(150-300)	410	360			333
Triglycerides (mg%)	(30-135)		163			
Alkaline Phosphatase, I.U.	(30-85)	2296	1960			1550
SGOT (units)	(10-50)	166	171			133
Albumin (gm%)	(3.4-4.4)	3.42		3.65		
α_1 globulin (gm%)	(0.1-0.3)	0.27		0.29		
α_2 globulin (gm%)	(0.5-0.7)	1.00		0.80		
β globulin (gm%)	(0.7-1.1)	1.46		1.03		
γ globulin (gm%)	(0.8-1.4)	2.56		2.04		
IgA	(0.14-0.26)			0.2		
IgG	(0.7-1.5)			1.17		
IgM	(0.07-0.13)			0.36		

Additional data: (6/22 to 6/26) Prothrombin time 12.9/12.9; thymol turbidity 12 units; Australia antigen negative; Serum Fe 210, TIBC 338; ESR 70 min/1 hr; antimitochondrial antibody 1:10; serum bile acids: trihydroxy 0.2, dihydroxy 2.6 mg% (normal: 1.4 ± 0.32; 0.43 ± 0.05).

abnormality. Histologic examination of the liver biopsy (Figure 2) revealed a marked infiltrate of chronic inflammatory (round) cells in the periportal spaces. There was a striking paucity of bile ducts and those still present were at times surrounded by epithelioid cells and multinucleated giant cells. There was a very early fibrosis in the portal spaces. No necrosis was seen. These findings were considered to be consistent with a cholangiolitic hepatitis-cirrhosis transition, or early "primary biliary" cirrhosis. Despite the excessive intake of alcohol there was no suggestion of alcoholic hepatitis or fatty metamorphosis.

Comment

Both cases were atypical for chronic cholangiolitic hepatitis-cirrhosis transitions. Neither patient had pruritus nor elevated serum bile acid concentrations and neither exhibited obvious jaundice (though with mild serum bilirubin elevations). One patient had hepatosplenomegaly and nodular cirrhosis; the other a slightly enlarged liver and spleen, but marked chronic hepatitis with very early fibrosis. In both cases, however, the serum alkaline phosphatase was greatly increased and the characteristic histologic evidence of cholangiolysis and granulomata was noted.

In Case 1 the common duct contained some 1 mm stones but there was no evidence of biliary obstruction either in the duct itself or in the liver, thus the cirrhosis was not believed to be of the obstructive or cholostatic type, but rather, in view of the histologic changes, of the primary cholangiolitic type. The minute stones in the gallbladder and common duct may have been caused by a change in composition of the bile due to the diffuse disturbance in the intrahepatic bile ducts.

The failure to find hepatitis associated antigen (HAA) in the blood of either case, is not surprising.

While most cases of cholangiolitic cirrhosis run true to form, there are deviant cases, very difficult to classify.[1,4,21] Granulomas are often encountered in cholangiolitic in contrast with other forms of cirrhosis.[13] It has been suggested that they may represent a reaction to damaged bile duct epithelium or may result from an altered immunologic state. Immunoglobulins, especially IgM and complement have been found by Paronetto and Popper[22] in the bile ducts. Large pyroninophilic cells in the portal tracts around small bile ducts have been shown to contain IgM.[22] Serum antibodies to mitochondria,[10] positive fluorescent antinuclear antibody[10,11] and rheumatoid factor[11] are commonly observed, as well as antibodies to bile duct epithelium[23] and smooth muscle.[10] Increased complement fixation titers have been reported.[6]

Etiology

Drugs

The histologic picture of "primary biliary" cirrhosis, including cholangiolysis, has been observed occasionally in patients receiving tolbutamide,[24] methyltestosterone,[25] and chlorpromazine.[26] Although the histologic change may revert to normal after cessation of the drug, irreversible and even fatal cases of cirrhosis presumed to be on such a chemical basis, have been reported. It may be that such chemicals serve to trigger an abnormal immune response, or chemical allergy, or that they activate a resident virus.

Virus

Recently, Krohn and associates[27] have revived interest in a viral etiology. By electron microscopy, they demonstrated particles similar to the Australia antigen in 11 of 12 patients with "primary biliary" cirrhosis. Antigen and/or antibody were found in nine of ten by means of immunoelectrophoresis. This finding has not yet been confirmed. Kaplan and Grady,[28] using conventional techniques, without electron microscopy, failed to demonstrate the Au antigen in a series of such cases. If the disease is secondary to a virus the usual absence of any history of infectious hepatitis[1,29] will have to be reconciled, possibly on the basis of a peculiar immunologic status.

The renewed interest in a viral etiology calls to mind a remarkable case reported in 1946.[17] The patient had infectious (epidemic) hepatitis at age 15, at which time her sister also had the disease but recovered completely. Thenceforth she had recurrent or waxing and waning jaundice for the remainder of her life. In brief she had long-standing pruritus, chronic jaundice and hepatosplenomegaly. The first biopsy at age 38 revealed chronic hepatitis. Ten years later she had definite cirrhosis on biopsy, which (on recent re-examination*) revealed a marked paucity of small bile ducts in the portal space quite compatible with a "cholangiolitic" hepatitis-cirrhosis transition. One year after this she died from a bleeding esophageal varix. The liver weighed 3,000 gms and presented a somewhat coarsely nodular appearance. It is reasonable to believe

*We are indebted to Dr. Robert Hebbel for examining this with us.

that this was related to the early attack of infectious hepatitis which resulted in a chronic active hepatitis, eventuating in cholangiolitic cirrhosis.

Treatment

No specific therapy is known. The prognosis is uniformly poor although the course is often long and chronic, ranging up to 18 years.[4,29] Treatment with steroids and 6-mercaptopurine has been of little value in halting the progression of the disease. Pruritus has often been satisfactorily controlled with bile acid sequestering resins,[30] although continued use may result in vitamin K or D deficiency, thus promoting a hemorrhagic tendency as well as the skeletal demineralization which the disease regularly imposes in varying degree.

Fischer and Schmid[31] have reported improvement in two cases following treatment with azathioprine. Alarcon-Segovia et al.[32] advocated using azathioprine to alleviate pruritus.

Summary

"Cholangiolitic" or "primary biliary" cirrhosis is a reasonably well defined clinical, immunologic and histologic entity, but cases with dysharmonious features are at times encountered, two of which are described. The term "cholangiolitic" is preferred because of the characteristic cholangiolysis and chronic hepatitis preceding the cirrhosis. Newer knowledge of the disease is reviewed and the relative importance of chemical, viral, and immunologic factors in etiology is considered. The histologic picture of the liver of a case reported 25 years ago, in which a viral etiology was strongly suspected, on re-examination revealed the presence of cholangiolysis, the importance of which had not been recognized at that time.

An important recent paper by Maddrey and associates[33] relating to 68 cases of primary biliary cirrhosis, reports failure to find HAA more frequently than in the population generally.

Acute Hyperthermia with Anesthesia

JOSEF K. WANG, M.D.*

ACUTE HYPERTHERMIA is a rare but potentially fatal complication of general anesthesia. It has followed all forms of general anesthesia. It affects apparently healthy patients undergoing relatively minor surgical procedures. In affected individuals general anesthesia causes a rapid rise in body temperature which, unless rapidly corrected by immediate cooling, is followed by convulsions and death.

The etiology of the acute hyperthermia is unknown, although it has been proposed as an uncoupling of oxidative phosphorylation[1] and as a result of sustained muscular contractions.[2]

A number of families have been reported in whom several members have suffered acute hyperthermia. The tendency to develop this complication appears to be inherited as an autosomal dominant characteristic.[3]

Recent clinical observations strongly suggest a link between this complication and some type of myopathy.[4,5,6,7] Biochemical estimations in the fatal cases showed very high serum-levels of creatine phosphokinase, phosphate and potassium.[4,6] It has also been described in a patient with myotonia congenita.[8]

All patients who are to undergo general anesthesia should be asked about any family history of acute hyperthermia or anesthetic deaths. Suspected patients should be examined clinically and screened by serum creatine phosphokinase levels, so that affected individuals can be warned not to have general anesthetics.[4] Several patients who have survived acute hyperthermia have later had no untoward effect from regional block.[3] Temperature monitoring should be routine during general anesthesia for those suspected so that acute hyperthermia can be corrected at the earliest possible stage.

In almost every instance of reported acute hyperthermia some degree of generalized muscular rigidity preceded the rise in body temperature. Some patients responded to succinylcholine with muscular rigidity. An unusual reaction to succinylcholine, or the development of the generalized muscular rigidity is sufficient grounds for canceling the operation.

Treatment of acute hyperthermia consists of effective cooling and correction of metabolic acidosis. It is not sufficient to apply ice bags to the body surface. Aggressive surface cooling by immersing the patient into ice water bath may be effective in children if begun early. The Wangensteen Gastric Hypothermia Unit affords a quick, simple and effective means of cooling during the period of tremendous heat production.[9] Exchange transfusion with compatible cool blood should be considered. The increased rate of metabolism indicates the necessity of mechanical ventilation with high inspired oxygen concentration. Adequate dosage of sodium bicarbonate or THAM should be given intravenously without hesitation and pharmacological support of a failing circulation is often required. Prophylactic measures, early recognition of this complication and prompt treatment will reduce the high mortality of acute hyperthermia.

Nasopharyngeal Carcinoma

JUDD H. CHIDLOW, M.D.* AND LAWRENCE W. DeSANTO, M.D.*

In carcinoma of the nasopharyngeal region, the problem is difficult because the site of the lesion is not easily approached and because the lesion is generally diagnosed late and has a tendency to metastasize early. The nasopharynx is hidden by the palatal curtain, is situated under the base of the skull, and is adjacent to the many vital structures in the skull as well as those of the lateral and posterior aspects of the neck.

Fortunately, malignant lesions in this region are relatively rare, comprising 0.05% of all malignancies; malignancies of the head and neck constitute 3%. Orientals, particularly the southern Chinese, have a higher incidence of nasopharyngeal lesions; such lesions account for 0.3 to 0.5% of all cancers. Cancer of the nasopharynx is the most common nasopharyngeal tumor in children and is often misdiagnosed because of the high incidence of malfunctioning eustachian tubes in this age group.

Cause

The cause is unknown, but recent studies have demonstrated high titers of anti-Epstein Barr virus in more than 50% of persons with proved nasopharyngeal cancer. Men are affected three times more often than women and have a poorer prognosis, as is true in most types of malignancies of the head and neck. The average age of the patients is in the fifth decade, and the average duration of symptoms prior to diagnosis is six to nine months. Generally, the patients feel well, until the advanced stage of the disease. The late diagnosis and aggressiveness of most of these tumors and their frequent metastases account for the poor prognosis.

Anatomic and Embryologic Features of the Nasopharynx

The nasopharynx is different embryologically from the lower food and airway passages. Because it develops as part of the nose, morphologically and functionally, the nasopharynx is related to the nose and not to the pharynx; its function is respiratory. This air-containing cavity, which occupies a space 4 by 4 by 2 cm, communicates anteriorly with the nose, laterally with the middle ears, and inferiorly with the oropharynx. The posterior wall is covered by squamous epithelium. The roof and lateral walls back to the eustachian tube orifices are typically covered with stratified ciliated columnar epithelium with mixed serous and mucus secreting glands. In the lateral walls between the patches of squamous and ciliated surfaces, some have found a transitional type of epithelium. The floor, that is, the dorsal surface of the soft palate, is continuous with the nasal passages and is lined with columnar ciliated epithelium. After trauma, whether by the adenotome or by chronic irritation of infection, respiratory epithelium changes to squamous epithelium.

The entire region is transversed by lymphatic vessels. Because these vessels communicate freely across the midline, bilateral metastatic involvement of cervical glands is common. However, one side is usually affected first. From the adjacent retropharyngeal nodes, the upper deep jugular nodes are next involved by tumor spread.

Diagnosis

As with all malignancies, early diagnosis is the key to successful treatment. The inaccessibility of the nasopharynx and the insidious onset of the tumors make early diagnosis particularly difficult. The patient's history and the use of the nasopharyngeal mirror, anterior rhinoscope, and the nasopharyngoscope are helpful in this regard.

Perhaps the earliest symptoms are those of a postnasal irritation, with repeated attempts to clear the throat in an effort to remove the focus of irritation. Usually, superficial ulcers streaked with fresh blood mixed with secretions are apparent next. Ciliary function is altered, leading to stagnation of secretions and halitosis. Nasopharyn-

*Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

geal tumors are not generally rapid growing.

The symptoms and signs are related to direct invasion of adjacent structures and to metastasis (Table 1). For diagnostic purposes, it is useful to categorize the manifestations into four groups: (1) nasopharyngeal, (2) otologic, (3) ophthalmoneurologic, and (4) metastatic. Nasopharyngeal manifestations include obstruction (either unilateral or bilateral), changes in speech (hyponasality or rhinolalia clausa), and anterior or posterior rhinorrhea, usually with bleeding. Otologic symptoms consist of obstruction of the eustachian tube, with conductive hearing loss. There may be otitis media, which is usually serous rather than purulent. All patients with unilateral serous otitis media must have an adequate nasopharyngeal examination. Extension of the tumor from the nasopharynx leads to neurologic abnormalities. All the cranial nerves are vulnerable, but the sixth nerve is most commonly involved. The resulting paralysis of the lateral rectus muscle leads to diplopia. Next most frequently involved, in order of decreasing frequency, are the fifth, third, and fourth cranial nerves. Headaches, difficulty in swallowing, and hoarseness may result if the tumor encompasses the vagus nerve. Metastatic extension, first to the retropharyngeal nodes and then to the upper deep jugular nodes, typically occurs early; a node between the mastoid process and angle of mandible is one of the first to be involved.

TABLE 1
Major Signs and Symptoms of Nasopharyngeal Carcinoma

Sign or symptom	Approximate per cent
Enlarged cervical lymph node	60
Blockage of ear(s)	40
Bloody nasal discharge	30
Nasal obstruction	<30
Speech changes	<30
Double vision	<30

Mirror

A complete ear, nose, throat, and neck examination should be done, after which attention is focused on the nasopharynx. The region is anesthetized with a topical spray. For best visualization, the largest nasopharyngeal mirror possible should be used; a No. 2 mirror usually is adequate. The nose should be constricted with neosynephrine or cocaine and epinephrine for the anterior rhinoscopy examination, and, if necessary, the nasopharyngoscope may be employed. Any bleeding on palpation of the lesion is suggestive of malignancy. Catheters inserted through the nose and out the mouth to elevate the soft palate are useful. Findings may be minimal, such as a fullness in the postnasopharyngeal wall, a narrow fossa of Rosenmüller with intact mucosa, or a compressed torus tubarius. The lateral bands may be enlarged. If there is a nontender node in the upper deep jugular chain, a biopsy specimen should be removed from any suspicious area in the nasopharynx. Submucosal tissue must be obtained, and often several specimens are needed from different areas of the tumors. The tissue should not be squeezed or traumatized any more than is absolutely necessary because this interferes with the microscopic diagnosis, which is difficult even under the best conditions. Roentgenograms of this region are valuable. Findings on sinus films, on roentgenograms of the lateral submento-vertical and occipitosubmental regions, and on tomograms may range from a small mass in the nasopharynx to slight enlargement of the foramina of the skull base or gross destruction of adjacent structures.

The clinical stages of nasopharyngeal carcinoma according to the American Joint Committee[1] in May 1965 are presented in Table 2.

TABLE 2
Clinical Stages of Nasopharyngeal Carcinoma, as Modified From the American Joint Committee[1] Report of May 1965

Stage	Comment
I	Tumor in one site of nasopharynx; that is, I: tumor in posterosuperior wall (valut) and II tumor in lateral wall
II	Tumor in two sites of nasopharynx
III	Clinically palpable cervical nodes that are no fixed
IV	Fixed nodes or distant metastasis

Generally, nasopharyngeal tumors are highly malignant and undifferentiated. The degree of anaplasia in different parts of the same tumor may vary widely from the primary site to the metastatic sites. The site of predilection is probably the fossa of Rosenmüller, but because the tumors usually are large when diagnosed, this is only speculation.

Treatment

Prior to 1900, cancer of the nasopharynx was treated with surgery and electrocoagulation, but the results were unsuccessful. Since that time surgery has had a minor role, being reserved for slow-growing low-grade tumors that rarely metastasize, such as angiofibrosarcomas, malignant

nixed tumors, and cylindromas, all of which are extremely rare in the nasopharynx.

^{60}Cobalt Irradiation

External megavoltage irradiation with ^{60}CO is the chief modality for the treatment of nasopharyngeal carcinoma. This consists of between 6,000 and 8,000 rads to the primary lesion during a six-week period. At the same time a slightly smaller dose is given to the neck, regardless of whether nodes are involved or not. Being thinner than the head, the neck requires about 10% less irradiation. The orbit, paranasal sinuses, and base of the skull are included with the primary site but the doses to each are different, depending on the extent of involvement. The submaxillary and submental nodes are not routinely included because they are rarely sites of metastasis. All other areas in the side of the neck above the clavicles are included, inasmuch as microscopic nests of tumor cells are more readily controlled than are large tumor masses.

Generally, lymphosarcomas are the most radiosensitive and require a lower dose. The more anaplastic the tumor, the better its initial response. Recurrences are frequent. Squamous cell carcinomas give the poorest irradiation response. Tumors that invade bone and nerves are more radioresistant. The shrinkage from treatment reduces pressures on nerves and therefore relieves pain and obstruction. The regression rate of a neoplasm is considered in determining the final dose. Radium seeding or onlays are used only after maximal external irradiation has been delivered.

Supportive therapy during irradiation consists of a high caloric and vitamin diet, dental hygiene, periodic hematologic checks, and careful observation.

The side effects and complications of irradiation thearapy are numerous (Table 3).

Chemotherapy

All cytotoxic drugs have deleterious side effects. The rationale for the prolonged administration of drugs is the subjection of the tumor cells to the continuous action of cytotoxic drugs at various phases of their vulnerability. Antimetabolites and alkylating agents are used most commonly. Evidence indicates that cancer cells are in the systemic circulation early in the disease. Some authors recommend the oral administration of methotrexate, 2.5 mg twice daily for seven to 10 days, to all patients who are being prepared for radiotherapy. However, most authors reserve chemotherapy for palliation after irradiation fails.

Surgery

Radical neck dissection is indicated for uncontrolled neck disease when the primary tumor in the nasopharynx is successfully treated. Occasionally, when neck dissections are done for persistent nodes after irradiation, no viable tumor cells are found.

TABLE 3
Complication of Irradiation in Carcinoma of the Nasopharynx

Site or type	Complication
Mouth	Loss of taste, dryness, mucositis, trismus, dehydration, dysphagia, and anorexia
Teeth	Ischemic devitalization, leading to radionecrosis of those in field (3rd molars especially)
Nasal cavity and paranasal sinuses	Mucositis, ulcers, suppurative maxillary sinusitis, possible fibrous adhesions, and fibrous atresia of choanae
Skin	Erythema, desquamation, blistering, and crusting (with conventional equipment); dry desquamation (with ^{60}Co)
Hair	Temporary epilation
Radiation sickness	Anorexia, nausea, and vomiting
Hemopoietic system	Depression of leukocytes and platelets
Brain stem	Myelitis and possible transverse myelitis
Larynx	Chronic laryngitis (transient); perichondritis (rare)
Bone	Osteitis of vertebrae and sinus walls
Muscles	Atrophy
Eyes	Conjunctivitis, keratitis (rare), and cataracts (rare)
Ears	Depressed cerumen gland in cartilage canal; fibrous muscular fixation, cochlear, and vestibular depression (rare)

Recurrences

Recurrences are common. Within 18 months, 50% of the patients will have recurrences that are clinically apparent, and recurrences have been noted as long as 10 years after treatment. About 30% of the patients will have recurrence at the primary site. Sixty-six per cent will have distant metastasis within two years and 80% within three years. Some radiotherapists use additional irradiation to recurrences, after careful evaluation of the patient. However, for the best chance of cure, the initial external roentgen therapy to the primary site and neck should be maximal. The management of distant metastasis to the skeletal system, liver, or lymph nodes is only palliative, but usually relieves pain. Radium seeds planted beneath the skin into the tumors are also palliative.

Prognosis (Table 4)

The prognosis is more favorable when the patient is young and is female and when the primary lesion is small. If cervical lymph nodes are involved, the prognosis is unfavorable and is even worse when there is bilateral involvement and the nodes are fixed. The time of recurrence after initial treatment is important. Recurrence after two years is associated with a better prognosis than earlier recurrence, as earlier recurrence denotes a more aggressive tumor.

TABLE 4
Average Five-year Survival in Nasopharyngeal Carcinoma

Lesion	Per cent
Early, without metastasis	50
Late, with cervical nodes involved	30
Far advanced	10

The histologic type is also an important factor in prognosis. The lymphoepithelioma and the transitional cell carcinoma are associated with a better progress than is the squamous cell carcinoma. Lymphosarcomas are rare, but respond well to irradiation. The prognosis is poor when the tumors are unclassified.

Summary

Cancer of the nasopharynx is a serious disease for which present modalities of treatment are far from optimal. Early diagnosis, prior to metastasis, offers the patient a better prognosis. Early diagnosis can be accomplished if every physician maintains a high index of suspicion when a patient has symptoms associated with the nasopharynx, ears, eyes, or nerves of the head and neck. The nasopharynx and neck must be carefully examined. The prognosis is poor for patients with nosopharyngeal carcinomas because of the insidious nature of the tumors and their tendency for early metastasis even before any symptoms are manifest.

Iodine Metabolism in Thyroid Function

HEINZ W. WAHNER, M.D.*

In analyzing thyroid function one wishes to elucidate two factors: (1) the level of the metabolic function of the body—that is, of hypothyroid, euthyroid, or hyperthyroid; and (2) the nature of the thyroid disease. In both of these approaches we make use of radioactive tracers, since the metabolism of the thyroid hormone is closely related to the metabolism of iodine. An understanding of thyroid function and a reasonable approach to the interpretation of thyroid function tests necessitates a thorough understanding of iodine metabolism.

Isotopes of Iodine

The isotopes of iodine used in thyroid testing and investigation are shown in Table 1. All emit gamma rays of various energies, ranging from 27 to 780 kev, and have half-lives ranging from two hours to 57 days. Some also emit beta particles. Beta particles emitted from isotopes of iodine cannot be used for external counting in-vivo because of their small tissue half-value layer, but they are effective in treating thyroid disease. ^{131}I and ^{125}I are used most frequently for clinical diagnostic and therapeutic purposes.

Regulation of Iodine Metabolism

The regulatory mechanism of iodine metabolism is diagrammed in Figure 1. Thyroid hormone acts on peripheral tissue to set the level of metabolism and is in turn itself degraded. As hormone is used in the peripheral tissue, the blood level decreases. This change is sensed by the pituitary and hypothalamus, TSH secretion is increased, and more thyroid hormone is secreted by the thyroid gland. The tissue action is the prime element in this sequence. The remaining elements serve to provide a constant supply to the tissues. This feedback mechanism regulates important parameters of iodine metabolism and is an important step which can be evaluated by laboratory methods such as the T3 suppression[1] and TSH stimulation tests.[2] TSH also can be measured directly by radioimmunoassay.[3] These three tests allow a differential diagnosis of primary (thyroid) and secondary (pituitary) hypothyroidism.

TABLE 1
Isotopes Useful in the Investigation, Diagnosis, and Treatment of Thyroid Disorders

Isotope	Half-life	Average β Emission (kev)	Equivalent β Emission Xray (kev)	Predominant γ Emission (kev)
^{123}I	13 hr	0	31	160
^{125}I	57 days	0	21	27
^{131}I	8 days	190	Negligible	364
^{132}I	2.3 hr	490	Negligible	670
				780
^{99m}Tc	6 hr	0	14	140

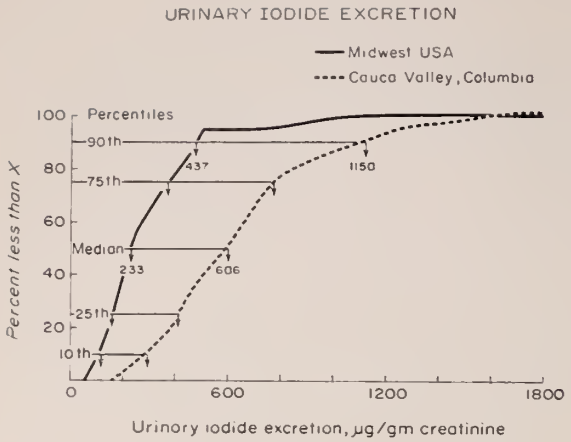

Fig. 2—Urinary iodide excretion in 185 subjects from endemic goiter area of Colombia, South America, and 66 subjects from middle western United States. Note higher urinary iodide excretion in subjects from Colombia.

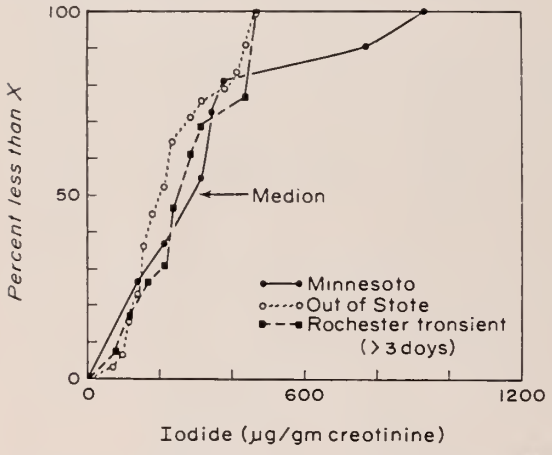

Fig. 3—Iodide excretion in 11 subjects from Minnesota, 42 subjects from other states of United States, and 15 subjects living in Rochester for more than three days. Note that there is very little difference in these groups.

Iodine Intake

Dietary iodine intake may vary from less than 50 µg/day, when we call the diet iodine-deficient, to more than 3,000 µg/day, as seen in the seaweed eaters in some Japanese islands. Other sources of iodine are drugs, food preservatives, skin lotions, and roentgenographic contrast media. The amount of iodine ingested is of paramount importance for the interpretation of all tests using radioactive tracers in—vivo. Therefore, before normal values are defined for a population, the range and the mean of the daily ingestion of iodine should be established. An accepted way to estimate the daily iodine intake is to measure the daily urinary iodine excretion.

The magnitude of the variation in iodine intake which may be expected is shown in Figure 2 which compares a population from Colombia, South America, and one from Rochester, Minnesota. That patients from various parts of the United States have about the same iodine intake is shown in Figure 3. In our affluent society, national food sources and habits are more important than location within a country. Several recent articles have demonstrated that normal ^{131}I uptake values are lower now than 10 years ago. This is because of an increase in dietary intake.

Metabolism of Inorganic Iodide

Ingested iodide is absorbed rapidly through the mucosa of the entire gut. Because of this rapid absorption, no clearcut evidence of iodine deficiency due to malabsorption has ever been documented. The iodide then circulates in the blood

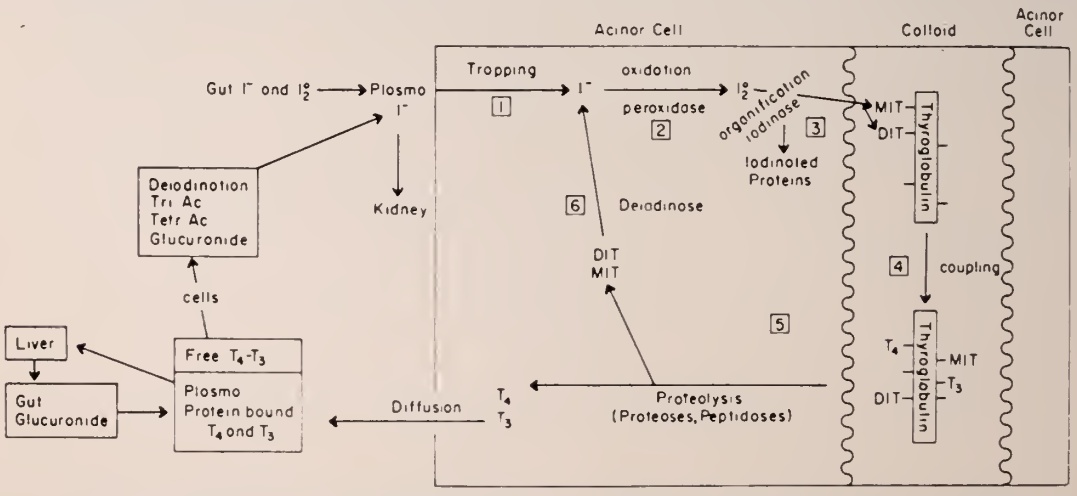

Fig. 4—Schematic representation of iodine metabolism. Arabic numerals depict known steps in hormone synthesis. (From Goodman, R. M.: Genetic Disorders of Man. Boston, Little, Brown & Company, 1970, p. 654. By permission.)

and is actively transported into thyroid tissue which maintains a 20- to 40-fold concentration gradient over the level of plasma (No. 1 in Figure 4). The iodide trap is estimated by early uptake measurements, Berson clearance, and techniques with pertechnetate ^{99m}Tc. Iodide can be discharged from the trap by perchlorate or thiocyanate, which is the basis for the perchlorate discharge test.

Through the action of a peroxidase and peroxide-forming enzymes, iodide is oxidized (No. 2 in Figure 4) and bound to tyrosine in thyroglobulin (No. 3). Organification is blocked by the thiourea drugs and a number of goitrogens. Iodinated tyrosine molecules in thyroglobulin are coupled to form iodothyronines (T3 and T4) (No. 4).

Thyroglobulin is synthesized on ribosomes in the thyroid cell, is transported slowly from the cell into the colloid, and is iodinated at the interface between cell and colloid. Iodinated thyroglobulin is stored in the colloid for an extensive period, averaging 50 to 100 days in healthy man.

For secretion, the colloid undergoes pinocytosis at the apical cell border, and colloid droplets are formed inside the cell. Fusion of lysosomes with these droplets produces a phagosome with a low internal pH, in which proteolytic enzymes and peptidases can degrade thyroglobulin into its component amino acids (No. 5).

The released T3 and T4 are secreted into the blood while the iodotyrosines are deiodinated and their iodide is recircled inside the gland (No. 6). The sequence so far can be evaluated by the thyroid uptake of ^{131}I. Conversion ratio and PB^{131}I are measurements of the speed with which ^{131}I is transformed into and excreted as hormone.

GENERAL OUTLINE

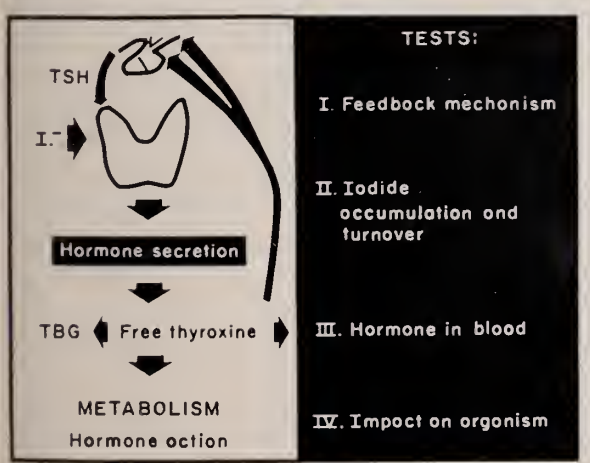

Fig. 5—Relationship of tests to thyroid physiology.

Metabolism of Organic Iodine

Normally, the thyroid gland secretes about 100 μg of thyroxine (T4) and 50μg of triiodothyronine (T3) per day. Alterations in the T4/T3 relationship have only recently been recognized as definable disease entities. The term "T3 hyperthyroidism" has been coined.[4,5] This ratio also may be altered in iodine deficiency,[6] in toxic nodular goiter,[7] as a premonitoring manifestation of thyrotoxicosis,[8] and after treatment with ^{131}I[9]. A correlation between elevated LATS levels and serum T3 levels has been found.[8] When T3 is significantly higher than normal, thyroid function tests may be difficult to interpret. The Sterling method[10] and a radioimmunoassay[11] are now available to measure T3 in serum; the normal value for the Sterling method is 220± 40 (SD) ng/100 ml.[12] About 30% of the total T3 in the blood is derived from conversion of T4 to T3 in the peripheral tissues.

Iodinated albumin is formed in association with iodothyroglobulin and may be released in small amounts normally, but this may be significantly increased in Hashimoto's thyroiditis or in rare patients with thyroid carcinoma. Also, some thyroglobulin is released into the circulation, probably via the lymphatics. Some iodide leaks from the thyroid gland, and iodotyrosines are found in the circulation in the presence of very hyperplastic glands.

In the blood T4 is bound to transporting proteins: thyroxine binding globulin (TBG), 75%; thyroxine binding albumin (TBA), 10 to 15%; and thyroxine binding prealbumin (TBPA), 10%. Approximately 0.05% of thyroid hormone remains free (FT4). An equilibrium exists between the bound and the free hormone. PBI, BEI, and total T4 are measurements of circulating thyroid hormone levels. TBG can be measured electrophoretically or by a simple charcoal adsorption method.[13]

Most modern thyroid laboratory screening tests are based on hormone measurements in the blood. An increase in thyroid binding proteins results in an increase in total circulating T4 but generally not in free T4. Exceptions are recognized. Distinct quantitative abnormalities of TBG, induced or congenital, are recognized and have to be considered in the interpretation of laboratory tests. Here free T4, direct determination of TBG, and T3 uptake tests are of importance.

T4 has a half-life of seven days in the blood. T3 has a half-life of 1.5 days. The disappearance rate of injected labeled hormone can be used as index of the cellular utilization of the hormone for the diagnosis of thyroid disfunction (specific activity test). In the cells thyroid hormone is degraded and the liberated iodine is partly recycled and partly excreted as iodide in the urine. There exists an enterohepatic circulation of conjugated T4, which is excreted in the bile, but this is of minor importance in man, and only in cases of severe gastrointestinal disorders or biliary diversion may it affect some tests.

Information about the size, position, and form of the gland can be obtained from the thyroid scan. The distribution of the tracer within the gland is also of diagnostic importance (cold and hot areas).

Summary

The thyroid lends itself to testing at four levels (Figure 5). The tests we use most frequent are illustrated in Table 2.

Acknowledgment

I acknowledge the help of Dr. C. A. Gorman and Dr. W. M. McConahey in discussions of this subject.

Intussusception: Revisited

The Duluth Experience from 1921—1966

JOHN V. THOMAS, M.D.

A STUDY OF intussusception in Duluth brought to light not only some interesting facts but uncovered a previous report on this same clinical problem presented by Dr. F. H. Magney. Dr. Magney's paper appeared in *Minnesota Medicine* 25 years ago. His study, plus the current data, provide an opportunity to observe this disease as experienced by the physicians in Duluth from 1921 thru 1966.

Summary of Dr. Magney's Study

In 1947 Dr. Magney described 25 years of experience with those cases subjected to surgery for intussusception. He stated: "The majority of Duluth physicians are of the opinion that the treatment is strictly surgical, and the so-called conservative methods were not attempted." Of 31 cases operated, when simple reduction of the intussusception was the only manipulation, there were eight deaths for a mortality of 28%. Of seven cases where resection and anastomosis and/or enterostomy were done, there were four deaths, 57% mortality. The overall mortality of 58 operations for intussusception was 26% (15 deaths). Dr. Magney called attention to improved measures of pre- and postoperative care by pointing out that whereas the mortality from 1921 to 1931 was 46.7%, the succeeding years from 1931 to 1946 showed only an 18% mortality. He underlined this fact by noting only two deaths among 17 patients operated between 1941 and 1946.

Address reprint requests to: John V. Thomas, M.D., 1029 Medical Arts Bldg., Duluth, Minn. 55802.

Present Study

For this report the medical records departments of St. Luke's and St. Mary's Hospitals selected all charts bearing the diagnosis of intussusception for the years 1939 to 1966, inclusive. Only those cases are reported in which a positive diagnosis could be made on the basis of recorded historical and physical findings and radiological or operative confirmation. A total of 86 cases in 84 patients was found. There were eight examples of intussusception in adults. Seventy-eight cases occurred in 76 children, all less than 13 years of age. Five patients died prior to 1951. All were children. The two recurrent cases will be described in detail.

Intussusception in Children

Age incidence in young children is demonstrated in Figure 1. Seven cases occurred from age four to 13 years and are not included in this figure. Seventy-seven percent were less than 24 months of age, and 63% were less than 12 months of age. Annual incidence of intussusception in Duluth between 1939 and 1966 is seen in Figure 2. No

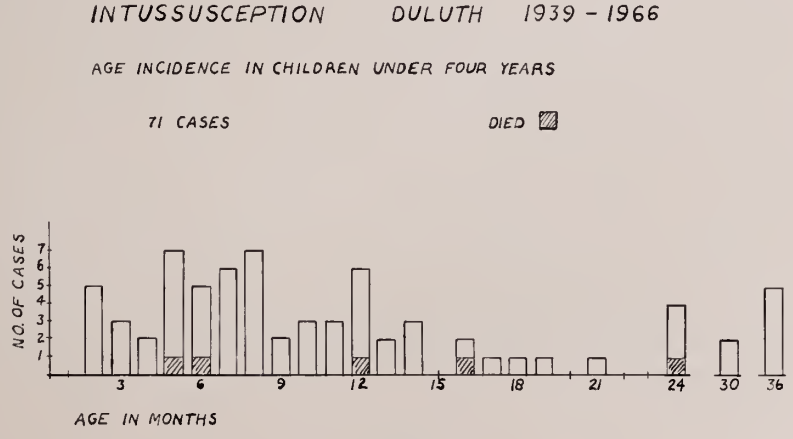

Figure 1

deaths were recorded between 1951 and 1966. Forty-three of the 76 children were male; 33 were female.

Intussusception is usually a sudden, abrupt incident in the life of an otherwise healthy child. Of the 78 examples, 61% exhibited symptoms for less than 24 hours prior to examination, and of these, more than half were examined within 12 hours of the onset of symptoms. Only 13% were first examined between 24 and 48 hours after onset of symptoms, and 23% after more than 48 hours of symptoms.

Dr. Magney emphasized that the three cardinal signs and symptoms of this disorder are intermittent colicky pain, vomiting, and bloody stools. In his report, 75% of 58 children showed all three and all of the cases exhibited at least one of these three symptoms.

In the present series, 65% of children have a history of bloody stool, passed a bloody stool when examined, or showed blood on the examiner's rectal glove. Vomiting occurred in 56%; abdominal cramps in 54%. An abdominal mass palpable in 41%, but in only 22% was the leucocyte count more than 15,000, and only 10% showed abdominal distension.

Treatment of Intussusception in Children

The paper by Dr. Magney, covering the period 1921 through 1945, reports only patients treated surgically. His statement that "the treatment is strictly surgical" reflects the prevailing concept of therapy during this period. Ware and Coffey[7] in 1950 were of the opinion that x-ray studies consumed time to the detriment of the child's welfare and that treatment was always early surgery.

For the present review of intussusception in Duluth, the mode of treatment was used to divide the patients into three groups: those treated by barium enema reduction alone; those treated by operative intervention alone; and those treated by barium enema followed by surgery because of failure of reduction. See Figure 3.

Group A, those treated by barium enema alone, (28 cases). In three patients the barium enema was negative and the charts suggested "spontaneous" reduction or reduction without radiographic demonstration. In 25 cases, hydrostatic reduction was accomplished; in 13 instances from the right colon, six times from the transverse colon, only twice from the left colon, and unspecified in four cases. There were no deaths and no complications recorded in this group.

Group B, those treated by surgery alone, (30 cases). Manual reduction as the only necessary surgical manuever was successful in 22 patients and no obvious mechanical cause for the intussusception was described. Ileo-ileal intussusception occurred only one and in this case two separate sites were reduced. Resectional surgery was necessary in the remaining eight cases. In one patient a necrotic Meckel's diverticulum leading the intussusception was excised, but in two cases where a Meckel's diverticulum was the leading point, it was necessary to include a segment of ileum in the resection. In one patient an ileal segment containing a benign polyp was

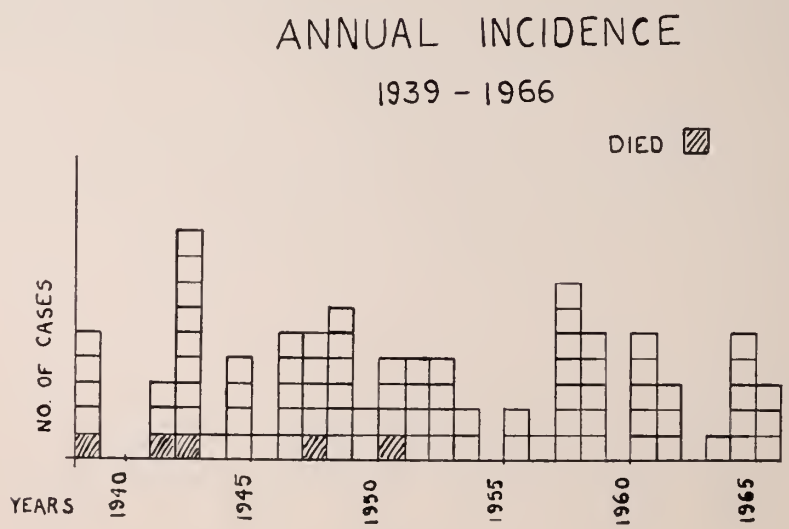

Figure 2

excised. Resection of a necrotic ileal segment was necessary once, right colectomy once, and resection of an ileo-colic segment twice. Appendectomy was performed seven times and the appendix was found to be acutely inflammed in three of these instances. Cecostomy was done in one patient and in five patients suture fixation of the terminal ileum was an additional procedure.

Group C, those treated by barium enema followed by surgical exploration, (20 cases). In two patients, the barium study was negative but the patients were explored, ileo-ileal intussusception found and manually reduced. In four instances, after positive x-ray evidence of obstruction, exploration failed to disclose an intussusception. Manual reduction at operation was successful in 11 cases. In one patient a Meckel's diverticulum was found to be the leading point and was excised. A Meckel's diverticulum, not thought to be causal, was excised from another patient. Segmental ileal resection was necessary twice, and excision of an ileo-colic segment once. In a single case, operative reduction was successful and a Meckel's diverticulum was noted, but excision was deferred and the diverticulum and the appendix were removed at a second operation one month later. Appendectomy was done in six cases; the appendix showed acute inflammation twice. Enterostomy was employed only once.

Complications and Mortality

The table lists all complications which occurred in Groups B and C. Of the 76 children treated for intussusception between 1939 and 1966, there were five deaths, a mortality rate of 6.6%. The five deaths occurred during the first 12 years of this study, among the first 45 cases collected. There were no recorded deaths related to intussusception between 1951 and 1966.

Case Reports

Case 1, 1939

A boy, aged five months, having had diarrhea for three days, bloody for one day, with vomiting, was admitted with a hemoglobin of 9.2 gm %. A barium enema done 24 hours after admission revealed an obstructing mass in the descending colon. At operation, an ileo-colic intussusception was reduced from the descending colon, and the bowel was observed to become pink. Postoperatively fever rose to 105° and the child expired 72 hours later. Autopsy revealed a necrotic right colon with perforation and peritonitis.

Case 2. 1942.

A two-year-old boy, with congential absence of the legs and right hand, was admitted with a five hour history of abdominal cramps, diarrhea and bloody stool. A rectal mass was palpable. Taken to surgery, anesthetic problems were encountered. An ileo-sigmoid intussusception was manually reduced but the child expired a few hours later due to vomiting and aspiration.

Case 3. 1943

A one-year-old female, with mongolism, was ill for 24 hours with abdominal pain and bloody stool, and an abdominal mass was palpable. A barium enema demonstrated an irreducible ileocecal intussusception. At operation successful reduction and excision of a Meckel's diverticulum was accomplished. The child expired five hours later. Autopsy revealed an interventricular septal defect.

Case 4. 1948

A girl, aged six months, had been ill for two days with

TABLE
Complication of Surgical Treatment of Intussusception in Children

	Surgery 30 Cases	B.E. + Surgery 20 Cases
Wound Infection	2	
P.O. Ileus	2	
Dehiscence		1
Fistula		1
"Stormy" Recovery	1	
Death	2	3

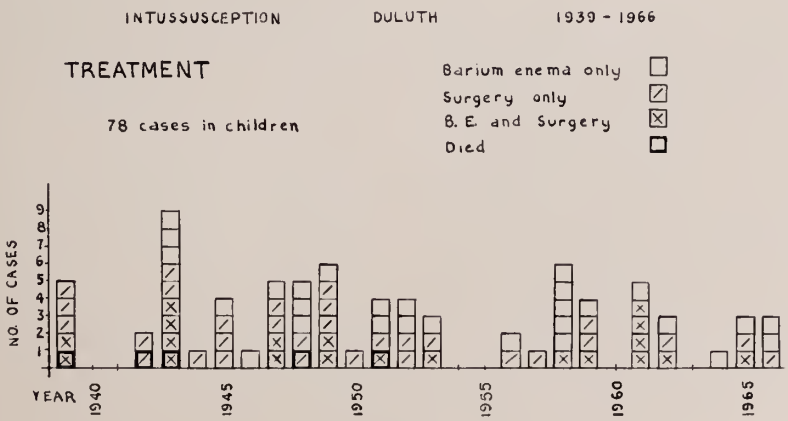

Figure 3

vomiting and bloody diarrhea. Dehydration was marked and a rectal mass palpable. Temperature on admission was 102° and the white count 16,800. She was given parenteral fluids but continued to vomit and have bloody diarrhea. Moribund, she was explored 26 hours after admission. An intussusception was reduced from the sigmoid and a necrotic cecum found. A right colectomy was done but the child expired in surgery.

Case 5. 1951

A girl, 16-months-old, vomited for three days, then had a bloody stool and was admitted. A mass was palpable in the left lower quadrant. A barium enema failed to completely reduce the intussusception. At operation, reduction was completed but gangrene of the terminal ileum required a segmental ileal resection. Postoperatively she was toxic with fever and vomiting. Gastric suction was employed but she expired 72 hours later. Autopsy revealed peritonitis due to anastomatic disruption and also pulmonary atelectasis.

Recurrent Intussusception

Two children exhibited recurrent episodes of intussusception, an incidence of 2.6%.

Case 6

A seven-month-old female, admitted with pain, vomiting and an abdominal mass, produced a bloody stool after an enema. An ileo-colic intussusception was reduced at operation. One month later she was admitted because of a bloody stool and an abdominal mass was again palpable. A barium enema failed to completely reduce the intussusception; operative reduction was successful. At surgery an acutely inflammed appendix was removed.

Case 7

A three-month-old girl was admitted after two hours of abdominal pain and passed bloody mucus from the rectum. A barium enema demonstrated but incompletely reduced an intussusception in the mid-transverse colon. Manual reduction of an ileo-colic intussusception and appendectomy were performed. Three years later, during a bout of upper respiratory infection, she complained of abdominal pain and nausea for 24 hours. No mass was palpable, but barium enema at this time successfully reduced an intussusception from the transverse colon.

Intussusception in Adults

Eight cases were found involving adults from ages 33 to 80 years; five were male. None passed blood by rectum. Pain and vomiting were predominant symptoms. In two cases a mass was palpable. A barium study of the colon was done in only two cases and demonstrated an ileal polyp in one, and a mass in the transverse colon of the other. All but one were surgically explored; the exception was a terminal patient with extensive metastases of melanocarcinoma. Manual reduction of the intussusception was performed in three patients, removing an intramural lipoma from two and the appendix from the third. A segmental ileal resection was necessary in three patients: an intramural lipoma, a fibroma, and a Meckel's diverticulum leading the intussusception in these cases. In one patient a carcinoma of the cecum was the point of the intussusception and necessitated a right colectomy.

Discussion

Although the etiology of intussusception has produced a great deal of speculation, most of the interest in this disease has focused upon treatment. Surgery continues to be the primary approach. Abbott, Cabell and Creech[1] in 1962 reported 96 cases in children, having used hydrostatic reduction in only 13 cases, with successful reduction in ten. Benson, Lloyd and Fischer[2] reported 300 cases in 1963, employing hydrostatic reduction only 25 times. Swenson and Oeconomopoulos[6] in 1962 reported 97 cases in children, using barium enema reduction only eighteen times but adding that the barium study was used diagnostically in twenty additional cases. These latter authors describe the advocates of reduction by barium enema as overenthusiastic. Among their criticisms of the hydrostatic method they included the uncertainty of satisfactory reduction, possible rupture of necrotic bowel, the loss of valuable time, and the fact that ileo-ileal intussusception cannot be reduced.

The 1959 monograph by Ravitch[4] describes in detail the use of hydrostatic reduction of intussusception and reports that 69% of 77 cases were successfully treated by this method without mortality. Dr. Ravitch emphasizes that barium enema reduction is applicable to all cases but that it must be a surgically supervised procedure, simultaneous with gastric lavage, blood and fluid replacement when indicated. The operating room should be in preparation while the barium enema is being administered, and at the first indication of incomplete or unsuccessful reduction laparotomy should be immediately undertaken.

The series here reported indicates that barium enema reduction was employed in 48 of the 78 cases in children, with successful reduction in 28 cases: a 58% success rate. It is also of interest to observe that among the first half of the study, those 39 cases from 1939 through 1950, a barium enema was used 20 times with successful reduction in 10 cases. In the second half of the study a barium enema was attempted 28 times with 18 successful reductions. Surgery was the primary approach in 19 cases of the first half but in only 11 instances from the latter portion of this study.

Recurrent intussusception was observed in two patients, both under one year of age. Soper and Brown[5] reviewed the literature collecting over

5000 cases, including 184 recurrences or 3.35%. However they reported that hydrostatic reduction was followed by a 9.96% recurrence rate, surgical reduction by only 3.1% recurrence. These authors noted that children exhibiting recurrent intussusception are more likely to demonstrate a specific etiologic mechanism, especially those children over eight years of age. They recommend that a second recurrence of intussusception be treated surgically and the involved intestine resected if the intussusception is the same type as had previously occurred.

Summary

This report provides an interesting review of the incidence and treatment of intussusception as observed and altered by the professional community of Duluth from 1921 through 1966. Two major trends are obvious: one, the abrupt change in mortality of this disease which accompanied the gains made in anesthesia, surgical technique, diagnostic methods and pre- and postoperative care; and second, the transition in approach to treatment from that exclusively surgical to a choice of method dependent on clinical features and diagnostic procedures. The low morbidity of barium enema reduction is noteworthy.

With regard to the etiology of intussusception, the reported cases illustrate the infrequency with which the surgeon can demonstrate a mechanical factor in children, and the converse observation in the adult when almost all cases showed a tumor leading the intussusception.

Intussusception does recur and should be considered as an entirely new event, with treatment based on the same tenets, with awareness however that a mechanical factor will be found more frequently in the older child.

Deaths from delay in treatment should not occur. Intussusception presents the physician with a unique example of bowel obstruction, usually in an infant, by nature ill-equipped to withstand abrupt changes in fluid and electrolyte balances. Treatment should be based on careful examination and a cautious trial of radiologically controlled hydrostatic reduction. Supportive measures include fluid and blood replacement when indicated. Prompt surgical intervention is dictated by signs of intestinal perforation or failure of hydrostatic reduction.

Screening for Something That Makes A Difference

"Aim high. Aim for something that makes a difference."—Peter F. Drucker

EACH YEAR 600,000 Americans die from coronary artery disease or its consequences. 165,000 of them are under 65.

One of the ways to cut this coronary count is to spot the man who's coronary prone.

Measuring Cholesterol and Triglycerides

How? We know of no better way than measuring a man's cholesterol and triglyceride levels, then, if either is elevated, determining his type of hyperlipoproteinemia.

Levels in Men with Infarcts

Consider this evidence. If you take a group of "normal" men in their fifties and measure their cholesterol and triglycerides, about 25 percent will have an elevated value of one or another test.[1] But take a group under 55 who have had myocardial infarcts, and the incidence of abnormal lipids jumps to nearly 60 percent.

Higher the Levels, Greater the Risks

Or look at it this way. Men who have cholesterol or triglyceride levels in the upper "quintile" (upper 20 percent of lipid levels in the population) run five to seven times the risk of myocardial infarction as those in the lower quintile.[2]

Phenotypes

Now, a little on hyperlipoproteinemia phenotypes: I, II, III, IV, and V. For practical purposes type I (a rare familial disease occurring mostly in children) and type V (a heterogeneous disorder characterized by abdominal crises and often secondary to other disease) have nothing to do with myocardial infarctions or coronary artery disease.

Types II, III, and IV

This leaves types II, III, and IV. Of these, type II and IV account for most people suffering from coronary artery disease. Type III is less common and usually manifests itself as peripheral arteriosclerosis. Other than these clinical differences, the main reason for separating hyperlipoproteinemias into types is that each type responds to different diets and drugs.

Preventing Infarcts

If we're going to prevent myocardial infarcts, we'll have to identify who's susceptible early enough. At present, the best way to do that is to measure serum cholesterol and triglycerides.

Knowing these levels could make a difference.

Any pathologist wishing to contribute material for this section is invited to do so.

Femininity & Vaginiti

Many women still believe that a douche is a cure-all for vaginal secretions and malodor. Mother tells daughter and the myth is perpetuated.

Other cosmetic products are not much better. Though they may be effective in some minor infections, they cannot touch the real medical problem, which very often is trichomonal vaginitis.

Medicine's most effective cure for trichomonal vaginitis is Flagyl® (metronidazole). It is also pleasantly feminine because it provides the simplicity of oral medication . . . frees women from the unpleasant mess and bother of douches.

When the problem is trichomonal vaginitis . . . remember Flagyl. It cures trichomoniasis with an unmatched high degree of effectiveness.

Flagyl is indicated for the treatment of trichomoniasis in both male and female patients and the sexual partners of patients with a recurrence of the infection provided trichomonads have been demonstrated by wet smear or culture.

Flagyl®

brand of (metronidazole)

Indications: For the treatment of trichomoniasis in both male and female patients and the sexual partners of patients with a recurrence of the infection provided trichomonads have been demonstrated by wet smear or culture. The oral form is indicated also for intestinal amebiasis and amebic liver abscess.

Contraindications: Evidence or history of blood dyscrasia, active organic disease of the CNS, the first trimester of pregnancy and a history of hypersensitivity to metronidazole.

Warnings: Use with discretion during the second and third trimesters of pregnancy and restrict to those pregnant patients not cured by topical measures. Flagyl (metronidazole) is secreted in the breast milk of nursing mothers. It is not known whether this can be injurious to the newborn.

Precautions: Mild leukopenia has been reported during Flagyl use; total and differential leukocyte counts are recommended before and after treatment with the drug, especially if a second course is necessary. Avoid alcoholic beverages during Flagyl therapy because abdominal cramps, vomiting and flushing may occur. Discontinue Flagyl promptly if abnormal neurologic signs occur. Exacerbation of moniliasis may occur. In amebic liver abscess, aspirate pus during metronidazole therapy.

Adverse Reactions: Nausea, headache, anorexia, vomiting, diarrhea, epigastric distress, abdominal cramping, constipation, a metallic, sharp and unpleasant taste, furry or sore tongue, glossitis and stomatitis possibly associated with a sudden overgrowth of *Monilia*, exacerbation of vaginal moniliasis, an occasional reversible moderate leukopenia, dizziness, vertigo, incoordination and ataxia, numbness or paresthesia of an extremity, fleeting joint pains, confusion, irritability, depression, insomnia, mild erythematous eruptions, "weakness," urticaria, flushing, dryness of the mouth, vagina or vulva, pruritus, dysuria, cystitis, a sense of pelvic pressure, dyspareunia, fever, polyuria, incontinence, decrease of libido, nasal congestion, proctitis, pyuria and darkened urine have occurred in patients receiving the drug. Patients receiving Flagyl may experience abdominal distress, nausea, vomiting or headache if alcoholic beverages are consumed. The taste of alcoholic beverages may also be modified. Flattening of the T wave may be seen in EKG tracings.

Dosage and Administration

For Trichomoniasis. In the Female: One 250-mg. tablet orally three times daily for ten days. Courses may be repeated if required in especially stubborn cases; in such patients an interval of four to six weeks between courses and total and differential leukocyte counts before, during, and after treatment are recommended. Vaginal inserts of 500 mg. are available for use, particularly in stubborn cases. *When the vaginal inserts are used,* one 500-mg. insert is placed high in the vaginal vault each day for ten days and the oral dosage is reduced to two 250-mg. tablets daily during the ten-day course of treatment. Do not use the vaginal inserts as the sole form of therapy. *In the Male:* Prescribe Flagyl only when trichomonads are demonstrated in the urogenital tract, one 250-mg. tablet two times daily for ten days. Flagyl should be taken by both partners over the same ten-day period when it is prescribed for the male in conjunction with the treatment of his female partner.

For Amebiasis. Adults: For acute intestinal amebiasis, 750 mg. orally three times daily for 5 to 10 days. For amebic liver abscess, 500 to 750 mg. orally three times daily for 5 to 10 days.

Children: 35 to 50 mg./kg. of body weight/24 hours, divided into three doses, orally for ten days.

Dosage forms: Oral tablets 250 mg.
Vaginal inserts 500 mg.

DYAZIDE®

Trademark

Each capsule contains 50 mg. of Dyrenium®
(brand of triamterene) and 25 mg. of hydrochlorothiazide.

CAN STOP POTASSIUM DEPLETION BEFORE IT STARTS

WITH NO SACRIFICE OF THIAZIDE EFFECTIVENESS

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

*Indications: Edema associated with congestive heart failure, cirrhosis of the liver, the nephrotic syndrome; steroid-induced and idiopathic edema; edema resistant to other diuretic therapy. Also, mild to moderate hypertension.

Contraindications: Pre-existing elevated serum potassium. Hypersensitivity to either component. Continued use in progressive renal or hepatic dysfunction or developing hyperkalemia.

Warnings: Do not use dietary potassium supplements or potassium salts unless hypokalemia develops or dietary potassium intake is markedly impaired. Enteric-coated potassium salts may cause small bowel stenosis with or without ulceration. Hyperkalemia (>5.4 mEq/L) has been reported in 4% of patients under 60 years, in 12% of patients over 60 years, and in less than 8% of patients overall. Rarely, cases have been associated with cardiac irregularities. Accordingly, check serum potassium during therapy, particularly in patients with suspected or confirmed renal insufficiency (e.g., elderly or diabetics). If hyperkalemia develops, substitute a thiazide alone. If spironolactone is used concomitantly with 'Dyazide', check serum potassium frequently—both can cause potassium retention and sometimes hyperkalemia. Two deaths have been reported in patients on such combined therapy (in one, recommended dosage was exceeded; in the other, serum electrolytes were not properly monitored). Observe patients on 'Dyazide' regularly for possible blood dyscrasias, liver damage or other idiosyncratic reactions. Blood dyscrasias have been reported in patients receiving Dyrenium (triamterene, SK&F). Rarely, leukopenia, thrombocytopenia, agranulocytosis, and aplastic anemia have been reported with the thiazides. Watch for signs of impending coma in acutely ill cirrhotics. Thiazides are reported to cross the placental barrier and appear in breast milk. This may result in fetal or neonatal hyperbilirubinemia, thrombocytopenia, altered carbohydrate metabolism and possibly other adverse reactions that have occurred in the adult. When used during pregnancy or in women who might bear children, weigh potential benefits against possible hazards to fetus.

Precautions: Do periodic serum electrolyte and BUN determinations. Do periodic hematologic studies in cirrhotics with splenomegaly. Antihypertensive effects may be enhanced in postsympathectomy patients. The following may occur: hyperuricemia and gout, reversible nitrogen retention, decreasing alkali reserve with possible metabolic acidosis, hyperglycemia and glycosuria (diabetic insulin requirements may be altered), digitalis intoxication (in hypokalemia). Use cautiously in surgical patients. Concomitant use with antihypertensive agents may result in an additive hypotensive effect.

Adverse Reactions: Muscle cramps, weakness, dizziness, headache, dry mouth; anaphylaxis; rash, urticaria, photosensitivity, purpura, other dermatological conditions; nausea and vomiting (may indicate electrolyte imbalance), diarrhea, constipation, other gastrointestinal disturbances. Rarely, necrotizing vasculitis, paresthesias, icterus, pancreatitis, and xanthopsia have occurred with thiazides alone.

Supplied: Bottles of 100 capsules.

1922: A Vintage Year for Minnesota Medicine

A DISTINGUISHED group of physicians began their practice in Minnesota in 1922 and now are being honored by induction into the Fifty Year Club of the Minnesota State Medical Association.

At the time of their graduation, most of them from the University of Minnesota Medical school, Warren G. Harding was the president soon to be replaced by his vice president, Calvin Coolidge. Jacob Preuss was Governor of Minnesota and J. F. Corbett, president of the MSMA. On the local scene in 1922 Lawrence Hodgson was mayor of St. Paul and across the river the mayor was General George E. Leach.

At the Palace Theater was playing "Adventures of Tarzan" with Elmo Lincoln, a serial with 15 electrifying episodes.

Thumbing through the *Saturday Evening Post* for 1922 one finds advertisements for versatile kitchen stoves that would burn coal, wood, *and* gas. One could buy marvelous cars with names like Jordan, Kissel, and Maxwell that certainly were beyond the reach of the medical class of '22. The affluent could buy a Chevrolet or Ford Roadster for about $500, but the majority transported their dates about town on the yellow street-cars that took them anywhere for five cents. However in the newspapers were letters to the editor complaining of the imminent raise of fare to six cents.

The Minneapolis Journal reported, "Minneapolis Symphony Orchestra, Emil Oberhoffer, conductor, soloist Engelbert Roentgen, violoncellist, perform a concert at 3:30 in the Minneapolis Auditorium."

Should children be deprived of milk because of "lactose intolerance?"

No, according to the Protein Advisory Group of the United Nations.

In a special report, the PAG stated, "It would be highly inappropriate, on the basis of present evidence, to discourage programs to improve milk supplies and increase milk consumption among children because of fear of milk intolerance." The statement emphasizes that low lactase activity and results obtained in tests with high lactose loads are not adequate indications of milk intolerance.
